## Pin Definitions

Pin Name	Pin No.	Pin Type	Pin Description
REF	1	I	<b>Reference Input:</b> The output signals Q0:3 will be synchronized to this signal unless the device is programmed to bypass the PLL.
Q0:3	2, 3, 5, 7	O	<b>Outputs:</b> These signals will be synchronous and of equal frequency to the signal input at pin 1.
QFB	8	O	<b>Feedback Output:</b> This output signal does not vary from signals Q0:3 in function, but is noted as the signal used to establish the propagation delay of nearly 0.
VDD	6	P	<b>Power Connections:</b> Connect to 3.3V. Use ferrite beads to help reduce noise for optimal jitter performance.
GND	4	P	<b>Ground Connections:</b> Connect all grounds to the common system ground plane.

## Overview

The W163 products are five-output zero delay buffers. A Phase-Locked Loop (PLL) is used to take a time-varying signal and provide five copies of that same signal out. The internal feedback to the PLL provides outputs in phase with the reference inputs.

the result is a significant amount of tracking skew which may cause problems in systems requiring synchronization.

For more details on Spread Spectrum timing technology, please see the Cypress Application note titled, "EMI Suppression Techniques with Spread Spectrum Frequency Timing Generator (SSFTG) ICs."

## Schematic

## Spread Aware

Many systems being designed now utilize a technology called Spread Spectrum Frequency Timing Generation. Cypress has been one of the pioneers of SSFTG development, and we designed this product so as not to filter off the Spread Spectrum feature of the Reference input, assuming it exists. When a zero delay buffer is not designed to pass the SS feature through,

### Notes:

- Longer input rise and fall time will degrade skew and jitter performance.
- All AC specifications are measured with a 50 $\Omega$  transmission line, load terminated with 50 $\Omega$  to 1.4V.
- Skew is measured at 1.4V on rising edges.
- Duty cycle is measured at 1.4V.
- For the higher drive -15, the load is 20 pF.
