# 68HC05K0 Infra-red Remote Control

#### Tony Breslin, MCU Applications Group, Motorola Ltd., East Kilbride, Scotland

The MC68HC05K0 is a low cost, low pin count single chip microcomputer with 504 bytes of user ROM and 32 bytes of RAM. The MC68HC05K0 is a member of the 68HC05K series of devices which are available in 16-pin DIL or SOIC packages. It uses the same CPU as the other devices in the 68HC05 family and has the same instructions and registers. Additionally, the device has a 15-stage multi-function timer and 10 general purpose bi-directional I/0 lines. A mask option is available for software programmable pull-downs on all of the I/O pins and four of the pins are capable of generating interrupts.

The device is ideally suited for remote-control keyboard applications because the pull-downs and the interrupt drivers on the port pins allow keyboards to be built without any external components except the keys themselves. There is no need for external pull-up or pull-down resistors, or diodes for wired-OR interrupts, as these features are already designed into the device.

This application makes use of many of the device features to control an infra-red television remote control. The application could be very easily modified to control any device with a similar transmission protocol. It will run on any of the 'K' devices without modification.

### **Remote Control Specifications**

The basic purpose of a television remote control is to transmit a control instruction to the television. The instruction is generated by a keystroke on the remote control keyboard. The detection and decoding of a key press and the transmission encoding is carried out by the remote control micro controller. When a key on the remote control keypad is pressed, the micro controller must first determine what key is being pressed and generate an individual code for the key. The key code is then converted to a instruction code that is inserted into the transmission command which, using a defined protocol, is transmitted to the television receiver. The command is continually transmitted as long as the key is being held down.

As the remote control is battery powered it needs to use as little power as possible. This is achieved by entering STOP mode when no keys are being pressed and effectively switches off the device. The micro controller comes out of STOP mode upon receipt of an interrupt request that is generated when a key is pressed.

### **Remote Control Keyboard**

The 68HC05K0 has ten general purpose I/O pins. One of these is used for the transmission signal output leaving nine pins for the keyboard control. Of these, four pins on PortA have internal interrupt request hardware. Using these four pins as inputs allows key presses to be detected without any external interrupt hardware. This leaves the five remaining pins for outputs.

Using the internal pull-down facility and the rising edge interrupt request on the four inputs permits interrupts to be generated. If the five outputs are set to logic '1', so driving an input from logic '0' to logic '1' when a key is pressed, an interrupt request can be generated. Using this arrangement a five by four keyboard matrix can be used. An extra four keys can be controlled if the Vdd line is used to drive one row of four keys to logic '1'. Therefore the maximum amount of keys controllable becomes twenty four.

Figure 1 Keyboard layout with associated scanned and transmitted codes

A depressed key will set one of the input columns to logic '1'. By scanning the columns, and setting each row output to logic '0' and then checking if the inputs all become logic '0', the associated row for the key can be determined. If rotating the logic '0' through the five output pins fails to identify a key column, then the key must be connected to the Vdd line. This process gives an individual code for each key which is a combination of the code from the column inputs and the row outputs. This can then be decoded to an instruction that is inserted into the output signal for transmission.

Figure 1 shows the layout of the keyboard on the left and the scanned and transmitted codes on the right. The keyboard layout incorporates the various television controls plus controls for TELETEXT. On the left hand side the codes returned from scanning the keyboard are shown in the upper right-hand corner of each key and the code sent for transmission for that key instruction are shown in the bottom left-hand corner. The I/O pins for each row and column are also shown for each key.

#### **Transmission Protocol**

The transmission protocol in this application is that used by the MC144105 IR Remote Control Transmitter. It uses a binary coded 9-bit data word with the LSB being transmitted first. Each bit of the transmitted signal is in the form of a bi-phase pulse code modulated (PCM) signal, whose bit coding is shown in Figure 2. For a transmitted '0' there is a 512 $\mu$ s pause followed by a 32kHz pulse train for 512 $\mu$ s. For a transmitted '1' there is 32kHz pulse train followed by a 512 $\mu$ s pause. This gives a bit time of 1024 $\mu$ s for all bits.This is shown asFigure 2.

Figure 2 Bit coding of PCM signal

A complete transmission command consists of several messages. Each command begins with a start message of nine 1's followed by the message appropriate to the key pressed. This message is repeatedly transmitted until the key is released. The transmission is terminated after the key is released by a end message of nine 1's.

Every message consists of a pre-bit, a pre-bit pause, a start bit and nine data bits. The pre-bit and the start-bit are always logical '1'. The pre-bit allows for the set up of the automatic gain control in the receiving preamplifier. Figure 3 gives the exact timing relationships for the transmissions. The command timing in Figure 3 shows that after the start transmission the message is continually re-transmitted at intervals of 131ms (approximately 8Hz) until the key is released. This is shown as time (c). The control timing shows the nine bit instruction 111001110 being transmitted starting with the LSB. The pre-bit pause is equal to two bit periods and is followed by a start-bit of logical '1'. The pulse train is continuous during the transition between transmitting a logic '0' and a logic '1'. The modulating pulse train has a frequency of approximately 32kHz with a mark-to-space ratio of one to three.

The signal for transmission is output through one port pin and is used to drive an IR diode amplifier circuit.

#### **Remote Control Operation**

Figure 4 is a flow diagram showing the operation of the remote control on power-up or reset. After the initial set-up of the ports as inputs or outputs the remote control goes into STOP mode. It will remain in STOP mode as long as the device is not reset or a key is not pressed. When a key is pressed an interrupt request is generated. A short time delay makes sure that it is a true key press and not noise and also allows time for any switching effects on the inputs to pass prior to checking the inputs.

The keyboard is then read to find which key has been pressed and the code for the key is decoded into an instruction and transmitted to the television. If the key is held down the instruction is re-transmitted until the key is released. This is useful for the instructions which count through the television channels or adjust the volume, colour or brightness controls.

When the key is released a terminating instruction is sent to the receiver to inform it that the next message received is a separate instruction. This is useful in the case of a one time instruction like sending a channel number. In this example the receiver will tune to a channel only once; to tune to another channel the key must be released and a new instruction sequence received.

After terminating the transmission the ports are reset ready for the next key press and the processor returns to the STOP mode.

Figure 4 Flow diagram

#### Hardware

The remote control circuit is shown in Figure 5. The hardware consists of the keyboard, the oscillator and the infra-red amplifier. The oscillator can be a crystal or a ceramic resonator with a frequency of 2MHz. The oscillator frequency is important since the transmission timing is based around a 1MHz internal clock frequency.

The infra-red amplifier uses two transistors and two standard diodes to limit the current through the IR diodes to approximately 1A. There is a need for a large capacitor close to the IR diodes because of the high switching current of the circuit.

Figure 5 Infra-red remote control

#### Software

The listing of the remote control assembler code is contained at the end of this application note. The first section of the listing sets up the ports prior to going into STOP mode and waiting for a key to be pressed. PortA bits 0-3 are set up as inputs with the pull-downs enabled. Bits 4-7 are set up as outputs logic '1' as is PortB bit 0. PortB bit 1 is set-up as output logic '0' to switch off the IR amplifier before going into STOP mode.

The next section of code named 'presd' is the routine pointed to by the interrupt vector and is entered when a key is pressed. This routine first calls the keyboard scanning routine to determine which key has been pressed. It then calls the decoding routine to convert the code from the keyboard to a code that will be accepted by the television. The start message is then transmitted and is followed by the instruction message. There is then a check to see if the same key is still being pressed. If it is then the instruction message is re-transmitted until the key is released and the end message is transmitted.

As the transmission protocol requires nine data bits and only one byte instructions are being decoded a flag has to be set for the ninth bit of the transmission routine. For the start and end transmissions this flag is set to 1 to give the nine 1's message. For all instructions the ninth bit is 0 so the flag is cleared.

The decoding routine compares the code from the keyboard scan routine with data array 'keydat'. On a match it takes the corresponding element from the array 'tvdat' as the instruction code for transmission.

The values of the instruction codes shown in the right-hand side of Figure 1 are specific for the receiver application. Each receiver using the same communications protocol will receive the same nine bit instruction but what the instruction does is

dependent upon the receiver software. In this example the eight bit instruction '14' changes the channel to number four. In another receiver application the receiver may interpret the instruction code '14' as increase volume.

The transmission routine is entered with the instruction for transmission in 'keyst3'. After the pre-bit and the start-bit are transmitted the instruction byte is rotated (LSB first) into the carry flag. A logic '1' is sent for transmission if the flag is set after rotation and a logic '0' is sent for transmission if the flag is cleared. Each bit is transmitted as shown in Figure 1. The routines 'send0' and 'send1' send a pause of 512us followed by a 32kHz pulse train for 512µs and a 32kHz pulse train for 512µs followed by a 512µs pause respectively. In the situation when a '1' follows a '0' then a pulse train of  $1024\mu s$  is required. To avoid breaks in this pulse train the 'send0' routine checks the next bit to be transmitted to see if a double length pulse train must be transmitted. The 'send1' routine then has to check that a double length pulse train has not been sent in the previous one and a half bit periods before sending a pulse train.

The routine 'burst' produces the 32kHz pulse train for a duration set by a count in the accumulator. As the instruction time for setting the PortB bit 1 pin high or low is five clock cycles then the minimum processor clock period is derived by dividing the minimum output state time, which is 8 $\mu$ s when the output is high, by the minimum number of clock cycles to change this state. This gives an internal clock period of 8 $\mu$ s/5 equalling 1.6 $\mu$ s. Adding a three cycle delay will require an internal clock period of 8 $\mu$ s/8 = 1 $\mu$ s, allowing a 2MHz oscillator to be used.

The code size is approximately 300 bytes, leaving memory space for more features to be added to the controller.

On applying power to the circuit the RESET vector will initialise the program counter at the beginning of the software. When examining the output at PortB bit 1 with an oscilloscope or logic analyser it should be noted that when trying to capture the signal by pressing a key the first signal out will be the start message of nine 1's. To capture the instruction the key should be held down and as the instruction will be continually re-transmitted then the capture can be initiated at this point.
