

Features

- Low start-up power supply voltage :1.7V(CH6)
- Wide supply voltage range from 2.4V to 6.5V (CH6); 3.6V to 6.5V(CH1~5)
- Up to 1MHz operating frequency
- Supports for down and up/down Zeta synchronous rectification conversion(CH1)
- Supports for up and up/down SEPIC synchronous rectification conversion(CH2, CH5)
- Supports for up, flyback and up/down SEPIC conversion
- AT1393/C: CH2,CH3, CH4 , CH5 and CH6
- AT1393A/B:CH2,CH3,CH5 and CH6
- Supports for inverting conversion
- AT1393A:CH4
- Synchronized rectification on CH1,CH2,CH5
- Power ON/OFF control function
- Built-in Soft-Start function
- Built-in Short-Circuit Protection circuit.
- LQFP 48 package

General Description

The AT1393 provides a complete power solution for digital still and video cameras through the integration of synchronous rectification topology , soft start function and short circuit detection function. This IC is ideal for applications that use either 2 or 3 alkaline or NIMH batteries as well as those using a single Li-ion battery.

Applications

- Digital Cameras
- CCD Imaging Devices
- Camcorders

Block Diagram

Application Circuit

Typical Characteristics

Function Description

1. Power Converter

* Reference voltage block

A temperature independent voltage of typical value at 2.50V is generated from the power source by the reference voltage circuit, which is used as a reference voltage for all internal circuitry and supplies load current to external device up to 1 mA.

* Triangular oscillator block

A triangular oscillation waveform is generated by connecting a timing resistor (RT) to pin 25 and a timing capacitor (CT) to pin 26. The resulting waveforms CT (amplitude at 0.3V to 0.8V), CT1 (in phase with CT with amplitude at 1.1V to 1.8V) and CT2 (reverse phase with CT with amplitude at 1.1V to 1.8V) serve as input to the PWM comparator.

* Error amplifier block

The error amplifier controls the error signal to the PWM comparator by sensing the DC/DC converter output voltage. Furthermore, by connecting feedback resistor and capacitor from the output pin to the inverted input pin of the error amplifier, an arbitrary loop gain can be set to make the system stable.

* Inverting amplifier block

The inverting amplifier detects the negative DC/DC converter output voltage and sends a control signal to the error amplifier.

* PWM comparator block

The PWM comparator converts the input voltage to pulse width and thereby the duty cycle of the DC/DC converter.

Channels 1, 2, and 5 main sides, channel 3, 4, and 6 : The comparator keeps the output transistor turn on while the error amplifier output voltage and DTC voltage are higher than the triangular wave voltage.

Channels 1, 2, and 5 synchronous rectification sides : The comparator keeps the output transistor turn on while the error amplifier output voltage are lower than the triangular wave voltage.

* Output block

A totem pole configuration is designed for the output block and can drive external MOSFET or transistor.

2. Channel Control

The channels are turned on and turned off according to the voltage levels at the CTL, CTL12, CTL3, CTL4, and CTL5 as described in the following table.

Voltage level at control (CTL) pin					Channel on/off status				
CTL	CTL1,2	CTL3	CTL4	CTL5	CH6	CH1,2	CH3	CH4	CH5
L	X	X	X	X	OFF (standby state)				
H	L	L	L	L	ON	OFF	OFF	OFF	OFF
				H					ON
			H	L				ON	OFF
				H					ON
		H	L	L		ON	ON	OFF	OFF
				H					ON
			H	L				ON	OFF
				H					ON
	H	L	L	L		ON	OFF	OFF	OFF
				H					ON
			H	L				ON	OFF
				H					ON
		H	L	L			ON	OFF	OFF
				H					ON
			H	L				ON	OFF
				H					ON

X : Don't care

3. Protective Functions

* Short circuit protection and timer latch

The comparator for short circuit detection in each channel detects the output voltage level of the power converter. When the output voltage falls below the short detection level, there will be a constant bias current charging the external capacitor C_{SCP} that is connected to the CSCP pin until the capacitor voltage level reaches about 0.7V and the output transistor turned off consequently. The actuated protection can be reset by restarting the power source.

* Under-voltage lockout protection

The under-voltage lockout protection is triggered when the supply voltage momentarily drops during transient, which may cause the IC to malfunction. To prevent such malfunctions, the under-voltage lockout protection circuit will turn off the output transistor, set the dead time to 100%, and hold the CSCP pin at the “L” level after detecting a decrease in internal reference voltage with respect to the power supply voltage,.

* Output switch control

When the power is turned on, output switch control circuit (SWIN = “L”) prevents the reactive current from flowing to external CH5 and CH6. After releasing UVLO and the C+IN6 pin voltage goes above 0.9V, if SWIN is “H” then SWOUT becomes “L” to turn on the external MOSFET and generate output voltage.

4. Soft Start Function

* The CTL, CTL1,2, CTL3, CTL4, and CTL5 terminals are driven to high level at the same time. The driving scheme is described in the following diagram.

* After CH6 soft start and driving the CTL1,2, CTL3, CTL4, and CTL5 to high level. The driving scheme is described in following diagram.

- (1) to (2) : CH6 soft start interval
(3) : VREF output start
(4) to (5) : CH1 to CH2 soft start interval
(6) to (7) : CH3 to CH5 soft start interval

* Soft start setting (for CH6)

Consider the input voltage and the load current to decide the value of the capacitor connected to the CIN6 pin. The soft start time $T_s(s)$ until the DC/DC converter output voltage of CH6 reaches 95% can be calculated by:

$$T_s(s) = 0.45 * C_1(\mu F)$$

* Soft start setting (for CH1 to CH5)

$$T_s(s) = 1.25 * C_s(\mu F)$$

Note : It could be disabled soft start function by floating CIN6 pin or CS pin.

Determine Oscillator Frequency

The triangular oscillator frequency is decided by the timing capacitor (C_T) and timing resistor (R_T) according to the following formula:

$$f_{osc}(KHz) = 900000 / (R_T(K\Omega) * C_T(pF))$$

DC/DC Output Voltage

* For CH1 to CH3, CH5 and CH6

* For CH4

*Using AT1393A CH4 as Inverting structure

*Using AT1383/AT1393 CH4 as negative voltage feedback structure

The CH6 Source Current

The output circuit of CH6 is illustrated in the following diagram. It can determine the output source current by defining the value of resistor R_B .

Note that the source current can be calculated by the following equation.

$$\text{Output source current} = (V_{RB}/R_B) * 210 \quad (\text{A})$$

Setting Time of Short Circuit Protection

The SCP comparator in each channel detects the output voltage to decide whether the power converter works at normal condition. At the same time, the voltage level of CSCP pin is held at low level. If the output load of these converters rapidly malfunction or become shorted, causing the output voltage to drop, the SCP comparator detects that and enables short circuit protection. The time period for short circuit protection is shown in the following equation.

Short detection time ($t_{PE}(s)$)

$$t_{PE}(s) = 0.7 * C_{SCP} (\mu F)$$

Note : It could be disabled short circuit protection function by connecting CSCP pin into the ground.

Setting the Dead Time Control Level

When using step up or Zeta or flyback DC/DC converter, it must prevent that output transistor works at full-ON state (ON duty = 100%). To prevent this situation, set the maximum duty of these channels. The dead time control circuit is implemented as below. When the voltage at the DTC1 pin is higher than the triangular wave voltage (CT1), the output transistor is turned on. The maximum duty calculation formula assuming that triangular wave amplitude = 0.7V and triangular wave minimum voltage = 1.1V.

$$Duty = [(V_d - 1.1) / 0.7] \times 100\%$$

Note 1 : The circuit is suitable at CH1 to CH5.

Note 2 : Shorting DTC and VREF to disable dead time control function.

Using CH4 Inv Amp.

When not using the CH4 INV Amp., connect the INA4 and OUTA4 each other.
