

Motor Drivers for Printers

Three-phase Brushless Motor Pre-drivers for Paper Feed

BD6761FS,BD6762FV

No.10016EAT01

Description

This product is the motor predriver for high-side/low-side N-channel MOS-FET drive, which has the built-in booster (step-up) circuit. BD6761FS uses the drive type controlled by the servo signal input from outside and BD6762FV incorporates a servo circuit (Speed discriminator + PLL servo).

Features

- 1) Predriver for high-side/low-side N-channel MOS-FET
- 2) Built-in booster (step-up) circuit
- 3) Built-in FG and hysteresis amplifiers
- 4) Built-in current limit circuit
- 5) Built-in thermal shutdown circuit
- 6) Built-in forward/reverse rotation switching circuit (BD6761FS, FD6762FV)
- 7) Built-in short brake circuit (BD6761FS, BD6762FV)
- 8) Built-in low voltage protection circuit (BD6761FS, BD6762FV)
- 9) Built-in speed lock detection circuit (BD6762FV)
- 10) Built-in motor lock protection circuit (BD6762FV)
- 11) Built-in start-stop circuit (BD6762FV)
- 12) Built-in servo circuit (Speed discriminator + PLL) (BD6762FV)
- 13) Built-in frequency multiplication circuit (BD6762FV)
- 14) 180°, direct PWM drive (BD6761FS)
- 15) 120°, slope switchable direct PWM drive (BD6762FV)

Applications

Main motor for paper feed of the laser beam printer and PPC

●Absolute Maximum Ratings (Ta=25°C)

Baramatar	Symbol	Rat	Lipit	
Falameter	Symbol	BD6761FS	BD6762FV	Unit
Applied voltage	VCC	36	36	V
Applied voltage	VG	36	36	V
Pin input voltage	Vin	VREG	VREG	V
Power dissipation	Pd	950 ^(※1)	1100 ^(※2)	mW
Operating temperature range	TOPR	-35 ~ +75	-25 ~ +75	S
Storage temperature range	TSTG	-40 ~ +150	-40 ~ +150	°C
Junction temperature	Tjmax	150	150	C

%1 Reduced by 7.6 mW/°C over 25°°C, when mounted on a glass epoxy board (70 mm × 70 mm × 1.6 mm). %2 Reduced by 8.8 mW/°C over 25°C, when mounted on a glass epoxy board (70 mm × 70 mm × 1.6 mm).

IC Operation

1) Hall input and output

For the hall input signal, the wave is shaped by the hall amplifier to generate the drive signal. This drive signal is amplified in the predriver block and the gate voltage is output for N-channel MOS FET.

2) PWM operation

PWM oscillating frequency is determined by the triangular waveform frequency which is decided by the external constant. This triangular waveform voltage and the listed voltage in the following chart are compared to perform PWM drive.

	Rfe, RFE	Cfe, CFE	Cfe, CFE pin charge/discharge current I	Frequency (Typ.)	Comparison voltage
BD6761FS	50kΩ	1000pF	1.6V/R	16.5kHz	Drive signal shaped by the hall amplifier
BD6762FV	20kΩ	1000pF	VRFE/R	16kHz	Integration amplifier output pin voltage

3) Booster circuit (step-up circuit) (common)

BD6761FS (Frequency = 62.5 kHz) and BD6762FV (Frequency = 125 kHz) generate the triangular waveform when the internal oscillator generates free-run oscillation and the rectangular waveform is generated at CP1. When a capacitor is connected between CP1 and CP2, and VG and GND, the step-up voltage is generated at VG pin. In this case, set VCC so that VG does not exceed the absolute maximum ratings (36 V).

	Triangular waveform oscillating	Charge pump voltage (VG pin
	frequency	voltage)
BD6761FS	62.5 kHz	VCC+6V
BD6762FV	125 kHz	VCC+6.7V

4) FG amplifier (common)

Set the FG amplifier gain so that the FGOUT pin is within the range of high and low output voltage and the amplitude is higher than the hysteresis width (250 mV: max) of the HYS amplifier.

FGSOUT pin uses an open collector format. Use in the condition as it is pulled up to the power supply with the resistor. At this time, pay attention so that the voltage higher than 36 V is not applied to the FGSOUT pin.

5) ACC, DEC circuits (BD6761FS)

When a resistor is connected to the RCP pin and the low voltage is input to the ACC pin, the current flows out from the CPOUT pin. When the low signal is input to the DEC pin, the current flows in to the CPOUT pin. Furthermore, when the ACC pin and DEC pin both set to low, the current flows in to the CPOUT pin. This current can be converted to the voltage by connecting a filter between the CPOUT and GND pins.

The voltage generated at the CPOUT pin controls the PWM's on-duty and maintains the constant motor rotation by inputting the controlled signal to ACC and DEC pins.

6) Current limit operation

When the CL voltage (BD6761FS) and RF voltage (BD6762FV) become the current limit voltage, the current limit circuit operates and works to limit PWM on_dutty. It also turns off the current limit circuit (current limit clear) at the peak of PWM triangular waveform and makes the current flow again. Output current lomax at this time are shown in the table.

	Current limit current
BA6761FS	lomax=0.48/RNF [A]
BA6762FV	Iomax=0.26/RNF [A]

7) Output simultaneous on prevention circuit (BD6761FS, BD6762FV)

When the low-side gate voltage becomes high while the high-side gate voltage is low, or when the high-side gate voltage becomes high while the low-side gate voltage is low, the simultaneous on prevention time is provided with t=3.2 μ s (TYP value). When the input capacity of external FET is C and the gate connection resistor is R, set R to satisfy the following equation so that the simultaneous on prevention time as mentioned above is not exceeded.

$$C \leq \frac{1.6\mu}{10 \times (24 + R)}$$

1 Q.

Check that the simultaneous on is not made in the actual operation and then set C and R.

Fig.13 High/Low-side Simultaneous On Prevention Timing Chart

8) Short brake (BD6761FS and BD6762FV)

BD6761FS operates the short brake action with the ACC and DEC pins set to low, and BD6762FV does with the SB pin set to OPEN or high. At the time of short brake, the high-side gate is turned off and the low-side is turned on. At the time of short brake operating, the current flows to the output FET, which is decided by the motor's counter electromotive voltage and coil impedance. Since this current flows via path which does not run through the overcurrent protection (current limit) detection resistor, the overcurrent protection does not operate as IC operating. Therefore, the current more than the overcurrent protection set current may flow to the output FET, pay attention so that it does not exceed the output FET rating.

9) Forward/reverse rotation circuit (BD6761FS and BD6762FV)

Forward /reverse rotation of motor can be switched according to the FR pin input conditions. Logics of the hall input and output conditions according to the FR pin input conditions are shown in the I/O conditions table (P.10). If the FR pin is switched during the motor rotation, since the simultaneous on prevention circuit in IC operates, the feed through current does not flow. However, since the motor current flows in the direction to the power source due to the electromotive force, the voltage may be raised if the power source does not have the power supply voltage absorption ability. Examine the capacitor characteristics between the power supply and ground sufficiently and then pay attention so that the power supply voltage and step-up voltage do not exceed the absolute maximum ratings. When the physical measures are taken such as increasing the capacitor value which is connected between the power supply and ground, check the characteristics enough prior to use.

10) Start/stop circuit (BD6762FV)

When the ST/SP pin is in the sate of OPEN or high, IC becomes standby. In the case of standby, some circuits operation are turned off to reduce the current consumption.

When the ST/SP pin is in the state of low, IC becomes operating.

11) Low voltage protection circuit (BD6761FS and BD6762FV)

This IC builds in the low voltage protection circuit. When VCC becomes lower than 11.5 V (Typ.), the high-side and low-side gates are both turned off to make the coil turn off. Protection off voltage is 12.0 V (Typ.) and hysteresis width is 0.5 V (Typ.). Since the motor locking protection detection circuit operates in BD6762FV during the low voltage protection operation, if the low voltage protection operating time becomes longer than the motor locking protection detection time, the operation moves to the motor locking protection operation after the low voltage protection.

12) Built-in 120° slope PWM logic (BD6762FV)

It is possible to perform 120° drive by setting 120/SL pin to OPEN or making high. 120° slope drive is possible by setting the 120/SL pin to OPEN or making high. Low noise design is realized by reducing the electromagnetic sound generated at the time of phase switching by means of gradually changing the output PWM on-duty during 120° slope energization. However, at the time of startup or the hall input frequency is lower than about 3 Hz (Typ. value), it becomes 120° drive. When the hall input frequency is more than about 3 Hz (Typ. value) and the rise of hall U-phase is detected 7 times, it switches to the 120° slope drive.

13) Servo circuit (BD6762FV)

Frequency multiplication circuit (Dividing period) (BD6762FV)

This IC builds in the frequency multiplication circuit.

Servo circuit is composed of the feedback loop as shown in the diagram and flows in/out the current ($22 \mu A$: Typ.) to the LPF pin (30 pin) by detecting the phase difference between the CLKIN pin (29 pin) and the frequency dividing unit output FCOMP. The phase difference signal output to the LPF pin (30 pin) is smoothed by the filter which is connected at the IC external of the LPF pin (30 pin) and this voltage is input to the VCO (Voltage control oscillation circuit) to decide the frequency for the internal signal FVCO. Since the dividing ratio of this frequency dividing unit is set to 1024, the relation of

FVCO[Hz]=1024 · FCOMP[Hz]

can be obtained, and the FCOMP and CLKIN have the same frequency according to the feedback loop as shown in the following diagram, therefore the multiplied frequency of 1024 times of FCOMP or CLKIN is acquired as the FVCO frequency.

Speed discriminator (BD6762FV)

The FGSOUT signal (28 pin) which detects the motor rotation speed and the reference clock in IC are compared and the acceleration/deceleration signal is output to the DOUT pin (32 pin). Reference clock is the signal (FVCO) that the CLKIN signal (29 pin) is multiplied by 1024. When the FG period is short to the reference clock period, it is determined that the motor revolution speed is too fast and the difference from the reference clock period is output to the DOUT pin as the deceleration command. When the FG period is long, the difference is output as an accelerating command.

• PLL (BD6762FV)

Phases of the FGSOUT (28 pin) signal which detected the motor revolution speed and the CLKIN (29 pin) input from the external are compared, and if the FG phase leads to CLKIN (28 pin), the difference is output as the deceleration command. If the FG phase lags, the difference is output as the acceleration command. • Integration amplifier (BD6762FV)

Speed error of the reference clock which is obtained in the speed discriminator block and the FG signal, and the phase difference signal of the CLKIN acquired in PLL block and the FG are integrated together and smoothed to become the DC voltage. This smoothed signal determines the PWM on-duty.

14) Speed lock detection circuit (BD6762FV)

When the motor speed is within $\pm 6.25\%$ range to the CLKIN signal (29 pin), L is output to the LD pin (36 pin) output. Since the LD pin (36 pin) has the open/drain output format, use as it is pulled up to the power supply with the resistor (100k Ω). At this time, pay attention so that the voltage more than 36 V is not applied to the LD pin.

15) Motor locking protection (BD6762FV)

Motor locking protection circuit judges he motor is in the locking condition when the motor speed is not in the lock range (preset value: $\pm 6.25\%$) and the motor locking detection time T_{LP} elapsed, the high-side and low-side output gates are both turned off.Motor locking protection can be cleared by making the condition Low after setting the ST/SP pin or the SB pin to OPEN or making high. Motor locking detection time T_{LP} is determined by the capacitor C7 which is connected to the LP pin and the count number CLP (preset value: 96) of the internal counter.

T_{LP}=2×10⁵×C7×CLP [S]

Notes for use

(1) Absolute maximum ratings

This product is subject to a strict quality management regime during its manufacture. Use of the IC in excess of absolute maximum ratings such as the applied voltage or operating temperature range may result in IC damage. Assumptions should not be made regarding the state of the IC (short mode or open mode) when such damage is suffered. A physical safety measure such as a fuse should be implemented when use of the IC in a special mode where the absolute maximum ratings may be exceeded is anticipated.

(2) Connecting the power supply connector backward

Connecting the power supply connector backwards may result in damage to the IC. For the protection of the IC from reversed connections, provide an appropriate measure, such as the insertion of an external diode each between the power supply and the power supply pin of the IC and between the motor coils.

(3) Power supply lines

The regenerated current resulting from the back EMF of the motor will return. Therefore, take an appropriate measure, such as the insertion of a capacitor between the power supply and GND. Determine the capacitance in full consideration of all the characteristics of the electrolytic capacitor, because the electrolytic capacitor may loose some capacitance at low temperatures. If the connected power supply does not have sufficient current absorption capacity, regenerative current will cause the voltage on the power supply line to rise, which combined with the product and its peripheral circuitry may exceed the absolute maximum ratings. It is recommended to implement a physical safety measure such as the insertion of a voltage clamp diode between the power supply and GND pins.

(4) GND potential

Ensure a minimum GND pin potential in all operating conditions.

(5) Setting of heat

Use a thermal design that allows for a sufficient margin in light of the power dissipation (Pd) in actual operating conditions.

(6) Pin shorts and mistake fitting

Use caution when orienting and positioning the IC for mounting on printed circuit boards. Improper mounting may result in damage to the IC. Shorts between output pins or between output pins and the power supply and GND pins caused by the presence of a foreign object may result in damage to the IC.

(7) Actions in strong magnetic field

Use caution when using the IC in the presence of a strong magnetic field as doing so may cause the IC to malfunction.

(8) ASO

When using the IC, set the output transistor so that it does not exceed absolute maximum ratings or ASO.

(9) Thermal shutdown circuit (TSD)

This IC incorporates a TSD circuit. If the chip becomes the following temperature, coil output to the motor will be open. The TSD circuit is designed only to shut the IC off to prevent runaway thermal operation. It is not designed to protect the IC or guarantee its operation. Do not continue to use the IC after operating this circuit or use the IC in an environment where the operation of the TSD circuit is assumed.

	TSD on temperature [°C] (Typ.)	Hysteresis temperature [°C] (Typ.)
BD6761FS	175	35
BD6762FV	175	23

(10) PWM drive

Voltage between the output FET drain and source may exceed the absolute maximum ratings due to the fluctuation of VCC at the time of PWM driving. If there is the threat of this problem, it is recommended to take physical countermeasures for safety such as inserting the capacitor between the VCC pin of FET and the detection resistor pin.

(11) Testing on application boards

When testing the IC on an application board, connecting a capacitor to a pin with low impedance subjects the IC to stress. Always discharge capacitors after each process or step. Ground the IC during assembly steps as an antistatic measure, and use similar caution when transporting or storing the IC. Always turn the IC's power supply off before connecting it to or removing it from a jig or fixture during the inspection process.

(12) Regarding input pin of the IC

This monolithic IC contains P+ isolation and P substrate layers between adjacent elements in order to keep them isolated.

P/N junctions are formed at the intersection of these P layers with the N layers of other elements to create a variety of parasitic elements.

For example, when a resistor and transistor are connected to pins as shown in Fig. 14,

- $\circ\,$ the P/N junction functions as a parasitic diode
- when GND > (Pin A) for the resistor or GND > (Pin B) for the transistor (NPN).
- Similarly, when GND > (Pin B) for the transistor (NPN), the parasitic diode described above combines
- with the N layer of other adjacent elements to operate as a parasitic NPN transistor.

The formation of parasitic elements as a result of the relationships of the potentials of different pins is an inevitable result of the IC's architecture. The operation of parasitic elements can cause interference with circuit operation as well as IC malfunction and damage. For these reasons, it is necessary to use caution so that the IC is not used in a way that will trigger the operation of parasitic elements, such as by the application of voltages lower than the GND (P substrate) voltage to input pins.

Fig. 14 Mimetic Diagram of Parasitic Element

(13) Ground Circuit Pattern

When using both small signal and large current GND patterns, it is recommended to isolate the two ground patterns, placing a single ground point at the application's reference point so that the pattern wiring resistance and voltage variations caused by large currents do not cause variations in the small signal ground voltage. Be careful not to change the GND wiring pattern of any external parts, either.
