

# CY14B104K/CY14B104M

# 4-Mbit (512 K × 8/256 K × 16) nvSRAM with Real Time Clock

### Features

- 25 ns and 45 ns access times
- Internally organized as 512 K × 8 (CY14B104K) or 256 K × 16 (CY14B104M)
- Hands off automatic STORE on power-down with only a small capacitor
- STORE to QuantumTrap nonvolatile elements is initiated by software, device pin, or AutoStore on power-down
- RECALL to SRAM is initiated by software or power-up
- High reliability
- Infinite read, write, and RECALL cycles
- 1 million STORE cycles to QuantumTrap
- 20 year data retention
- Single 3 V +20%, -10% operation
- Data integrity of Cypress nvSRAM combined with full-featured real time clock (RTC)

- Watchdog timer
- Clock alarm with programmable interrupts
- Capacitor or battery backup for RTC
- Industrial temperature
- 44-pin and 54-pin thin small outline package (TSOP) Type II
- Pb-free and restriction of hazardous substances (RoHS) compliant

### **Functional Description**

The Cypress CY14B104K and CY14B104M combines a 4-Mbit nonvolatile static RAM (nvSRAM) with a full-featured RTC in a monolithic integrated circuit. The embedded nonvolatile elements incorporate QuantumTrap technology producing the world's most reliable nonvolatile memory. The SRAM is read and written infinite number of times, while independent nonvolatile data resides in the nonvolatile elements.

The RTC function provides an accurate clock with leap year tracking and a programmable, high accuracy oscillator. The alarm function is programmable for periodic minutes, hours, days, or months alarms. There is also a programmable watchdog timer for process control.

## **Pin Definitions**

| Pin Name                           | I/O Type     | Description  |
|------------------------------------|--------------|--|
| $A_0 - A_{18}$                     | Input        | Address inputs. Used to select one of the 524,288 bytes of the nvSRAM for × 8 configuration.   |
| $A_0 - A_{17}$                     |              | Address inputs. Used to select one of the 262,144 words of the nvSRAM for × 16 configuration.  |
| $DQ_0 - DQ_7$                      | Input/Output | Bidirectional data I/O lines for × 8 configuration. Used as input or output lines depending on operation.  |
| DQ <sub>0</sub> – DQ <sub>15</sub> |              | Bidirectional data I/O lines for × 16 configuration. Used as input or output lines depending on operation.   |
| NC                                 | No connect   | No connects. This pin is not connected to the die.   |
| WE                                 | Input        | Write Enable input, Active LOW. When selected LOW, data on the I/O pins is written to the specific address location.   |
| CE                                 | Input        | Chip Enable input, Active LOW. When LOW, selects the chip. When HIGH, deselects the chip.  |
| ŌĒ                                 | Input        | <b>Output Enable, Active LOW</b> . The active LOW OE input enables the data output buffers during read cycles. Deasserting OE HIGH causes the I/O pins to tristate.                          |
| BHE                                | Input        | Byte High Enable, Active LOW. Controls DQ <sub>15</sub> -DQ <sub>8</sub> .   |
| BLE                                | Input        | Byte Low Enable, Active LOW. Controls DQ7-DQ0.   |
| X <sub>out</sub> <sup>[6]</sup>    | Output       | Crystal connection. Drives crystal on startup.   |
| X <sub>in</sub> <sup>[6]</sup>     | Input        | Crystal connection. For 32.768 kHz crystal.  |
| V <sub>RTCcap</sub> <sup>[6]</sup> | Power supply | Capacitor supplied backup RTC supply voltage. Left unconnected if V <sub>RTCbat</sub> is used.   |
| V <sub>RTCbat</sub> <sup>[6]</sup> | Power supply | Battery supplied backup RTC supply voltage. Left unconnected if V <sub>RTCcap</sub> is used.   |
| INT <sup>[6]</sup>                 | Output       | <b>Interrupt output</b> . Programmable to respond to the clock alarm, the watchdog timer, and the power monitor. Also programmable to either active HIGH (push or pull) or LOW (open drain). |

#### Notes

Address expansion for 8-Mbit. NC pin not connected to die.
 Address expansion for 16-Mbit. NC pin not connected to die.
 Left unconnected if RTC feature is not used.

| <b>Pin Definitions</b> | (continued) |
|------------------------|-------------|
|------------------------|-------------|

| Pin Name         | I/O Type     | Description   |
|------------------|--------------|---|
| V <sub>SS</sub>  | Ground       | Ground for the device. Must be connected to ground of the system.   |
| V <sub>CC</sub>  | Power supply | Power supply inputs to the device. 3.0 V +20%, -10%   |
| HSB              |              | Hardware STORE Busy (HSB)<br>Output: Indicates busy status of nvSRAM when LOW. After each Hardware and Software STORE<br>operation, HSB is driven HIGH for a short time (t <sub>HHHD</sub> ) with standard output high current and then a<br>weak internal pull-up resistor keeps this pin HIGH (external pull-up resistor connection optional).<br>Input: Hardware STORE implemented by pulling this pin LOW externally. |
| V <sub>CAP</sub> | Power supply | AutoStore capacitor. Supplies power to the nvSRAM during power loss to store data from SRAM to nonvolatile elements.  |

## **Device Operation**

The CY14B104K/CY14B104M nvSRAM is made up of two functional components paired in the same physical cell. These are a SRAM memory cell and a nonvolatile QuantumTrap cell. The SRAM memory cell operates as a standard fast static RAM. Data in the SRAM is transferred to the nonvolatile cell (the STORE operation), or from the nonvolatile cell to the SRAM (the RECALL operation). Using this unique architecture, all cells are stored and recalled in parallel. During the STORE and RECALL operations SRAM read and write operations are inhibited. The CY14B104K/CY14B104M supports infinite reads and writes similar to a typical SRAM. In addition, it provides infinite RECALL operations. See Truth Table For SRAM Operations on page 25 for a complete description of read and write modes.

### SRAM Read

The <u>CY14B104K/CY14B104M</u> performs a read cycle when  $\overline{CE}$ and  $\overline{OE}$  are LOW, and WE and HSB are HIGH. The address specified on pins A<sub>0-18</sub> or A<sub>0-17</sub> determines which of the 524,288 data bytes or 262,144 words of 16 bits each are accessed. Byte enables (BHE, BLE) determine which bytes are enabled to the output, in the case of 16-bit words. When the read is initiated by an address transition, the outputs are valid after a delay of t<sub>AA</sub> (read cycle 1). If the read is initiated by CE or OE, the outputs are valid at t<sub>ACE</sub> or at t<sub>DOE</sub>, whichever is later (read cycle 2). The data output repeatedly responds to address changes within the t<sub>AA</sub> access time without the need for transitions on any control input pins. <u>This</u> remains valid until <u>another ad</u>dress change or until CE or OE is brought HIGH, or WE or HSB is brought LOW.

### **SRAM Write**

A write cycle is performed when  $\overline{CE}$  and  $\overline{WE}$  are LOW and  $\overline{HSB}$  is HIGH. The address inputs must be stable before entering the write cycle and must remain stable until  $\overline{CE}$  or  $\overline{WE}$  goes HIGH at the end of the cycle. The data on the common I/O pins  $DO_{0-15}$  are written into the memory if it is valid  $t_{SD}$  before the end of a  $\overline{WE}$  controlled write or before the end of an  $\overline{CE}$  controlled write. The Byte Enable inputs (BHE, BLE) determine which bytes are written, in the case of 16-bit words. It is recommended that  $\overline{OE}$  be kept HIGH during the entire write cycle to avoid data bus contention on common I/O lines. If  $\overline{OE}$  is left LOW, internal circuitry turns off the output buffers  $t_{HZWE}$  after  $\overline{WE}$  goes LOW.

### AutoStore Operation

The CY14B104K/CY14B104M stores data to the nvSRAM using one of three storage operations. The<u>se three</u> operations are: Hardware STORE, activated by the HSB; Software STORE, activated by an address sequence; AutoStore, on device power-down. The AutoStore operation is a unique feature of QuantumTrap technology and is enabled by default on the CY14B104K/CY14B104M.

During a normal operation, the device draws current from  $V_{CC}$  to charge a capacitor connected to the  $V_{CAP}$  pin. This stored charge is used by the chip to perform a single STORE operation. If the voltage on the  $V_{CC}$  pin drops below  $V_{SWITCH}$ , the part automatically disconnects the  $V_{CAP}$  pin from  $V_{CC}$ . A STORE operation is initiated with power provided by the  $V_{CAP}$  capacitor.

**Note** If the capacitor is not connected to  $V_{CAP}$  pin, AutoStore must be disabled using the soft sequence specified in Preventing AutoStore on page 6. In case AutoStore is enabled without a capacitor on  $V_{CAP}$  pin, the device attempts an AutoStore operation without sufficient charge to complete the Store. This corrupts the data stored in nvSRAM.

chip. A pull-up should be placed on  $\overline{\text{WE}}$  to hold it inactive during power-up. This pull-up is effective only if the  $\overline{\text{WE}}$  signal is tristate during power-up. Many MPUs tristate their controls on power-up. This should be verified when using the pull-up. When the nvSRAM comes out of power-on-RECALL, the MPU must be active or the WE held inactive until the MPU comes out of reset.

To reduce unnecessary nonvolatile STOREs, AutoStore, and Hardware STORE operations are ignored unless at least one write operation has taken place since the most recent STORE or RECALL cycle. Software initiated STORE cycles are performed regardless of whether a write operation has taken place.

### Hardware STORE (HSB) Operation

The CY14B104K/CY14B104M provides the  $\overline{\text{HSB}}$  pin to control and acknowledge the STORE operations. The  $\overline{\text{HSB}}$  pin is used to request a Hardware STORE cycle. When the HSB pin is driven LOW, the CY14B104K/CY14B104M conditionally initiates a STORE operation after t<sub>DELAY</sub>. An actual STORE cycle begins only if a write to the SRAM has taken place since the last STORE or RECALL cycle. The HSB pin also acts as an open drain driver (internal 100 k $\Omega$  weak pull-up resistor) that is internally driven LOW to indicate a busy condition when the STORE (initiated by any means) is in progress.

**Note** After each Hardware and Software STORE operation  $\overline{\text{HSB}}$  is driven HIGH for a short time ( $t_{\text{HHHD}}$ ) with standard output high current and then remains HIGH by internal 100 k $\Omega$  pull-up resistor.

SRAM write operations that are in progress when  $\overline{\text{HSB}}$  is driven LOW by any means are given time ( $t_{\text{DELAY}}$ ) to complete before the STORE operation is initiated. However, any SRAM write cycles requested after  $\overline{\text{HSB}}$  goes LOW are in<u>hibited</u> until  $\overline{\text{HSB}}$ returns HIGH. In case the write latch is not set,  $\overline{\text{HSB}}$  is not driven LOW by the CY14B104K/CY14B104M. But any SRAM read and write cycles are inhibited until  $\overline{\text{HSB}}$  is returned HIGH by MPU or other external source.

During any STORE operation, regardless of how it is initiated, the CY14B104K/CY14B104M continues to drive the HSB pin LOW, releasing it only when the STORE is complete. Upon completion of the STORE operation, the nvSRAM memory access is inhibited for  $t_{LZHSB}$  time after HSB pin returns HIGH. Leave the HSB unconnected if it is not used.

### Hardware RECALL (Power-Up)

During power-up or after any low power condition ( $V_{CC}$ <br/> $V_{SWITCH}$ ), an internal RECALL request is latched. When V<sub>CC</sub> again exceeds the V<sub>SWITCH</sub> on powerup, a RECALL cycle is automatically initiated and takes t<sub>HRECALL</sub> to complete. During this time, the HSB pin is driven LOW by the HSB driver and all reads and writes to nvSRAM are inhibited.

#### Software STORE

Data is transferred from the SRAM to the nonvolatile memory by a software address sequence. The CY14B104K/CY14B104M <u>Software STORE cycle is initiated by executing sequential CE or</u> OE controlled read cycles from six specific address locations in exact order. During the STORE cycle, an erase of the previous nonvolatile data is first performed, followed by a program of the nonvolatile elements. After a STORE cycle is initiate, further input and output are disabled until the cycle is completed.

Because a sequence of reads from specific addresses is used for STORE initiation, it is important that no other read or write accesses intervene in the sequence, or the sequence is aborted and no STORE or RECALL takes place. To initiate the Software STORE cycle, the following read sequence must be performed:

- 1. Read address 0x4E38 Valid READ
- 2. Read address 0xB1C7 Valid READ
- 3. Read address 0x83E0 Valid READ
- 4. Read address 0x7C1F Valid READ
- 5. Read address 0x703F Valid READ
- 6. Read address 0x8FC0 Initiate STORE cycle

The software sequence may be clocked with  $\overline{CE}$  controlled reads or  $\overline{OE}$  controlled reads, with  $\overline{WE}$  kept HIGH for all the six READ sequences. After the sixth address in the sequence is entered, the STORE cycle commences and the chip is disabled. HSB is driven LOW. After the t<sub>STORE</sub> cycle time is fulfilled, the SRAM is activated again for the read and write operation.

#### Software RECALL

Data is transferred from the nonvolatile memory to the SRAM by a software address sequence. A software RECALL cycle is initiated with a sequence of read operations in a manner similar to the Software STORE initiation. To initiate the RECALL cycle, perform the following sequence of CE or OE controlled read operations:

- 1. Read address 0x4E38 Valid READ
- 2. Read address 0xB1C7 Valid READ
- 3. Read address 0x83E0 Valid READ
- 4. Read address 0x7C1F Valid READ
- 5. Read address 0x703F Valid READ
- 6. Read address 0x4C63 Initiate RECALL cycle

Internally, RECALL is a two step procedure. First, the SRAM data is cleared; then, the nonvolatile information is transferred into the SRAM cells. After the  $t_{RECALL}$  cycle time, the SRAM is again ready for read and write operations. The RECALL operation does not alter the data in the nonvolatile elements.

#### Table 1. Mode Selection

| CE | WE | OE | BHE, BLE <sup>[7]</sup> | A <sub>15</sub> –A <sub>0</sub> <sup>[8]</sup>           | Mode   | I/O  | Power                                  |

### **Preventing AutoStore**

The AutoStore function is disabled by initiating an AutoStore disable sequence. A sequence of read operations is performed in a manner similar to the Software STORE initiation. To initiate the AutoStore disable sequence, the following sequence of CE or OE controlled read operations must be performed:

- 1. Read address 0x4E38 Valid READ
- 2. Read address 0xB1C7 Valid READ
- 3. Read address 0x83E0 Valid READ
- 4. Read address 0x7C1F Valid READ
- 5. Read address 0x703F Valid READ
- 6. Read address 0x8B45 AutoStore Disable

The AutoStore is re-enabled by initiating an AutoStore enable sequence. A sequence of read operations is performed in a manner similar to the software RECALL initiation. To initiate the

AutoStore enable sequence, the following sequence of  $\overline{CE}$  or  $\overline{OE}$  controlled read operations must be performed:

- 1. Read address 0x4E38 Valid READ
- 2. Read address 0xB1C7 Valid READ
- 3. Read address 0x83E0 Valid READ
- 4. Read address 0x7C1F Valid READ
- 5. Read address 0x703F Valid READ
- 6. Read address 0x4B46 AutoStore Enable

If the AutoStore function is disabled or re-enabled, a manual STORE operation (hardware or software) must be issued to save the AutoStore state through subsequent power-down cycles. The part comes from the factory with AutoStore enabled and 0x00 written in all cells.

- 7. BHE and BLE are applicable for × 16 configuration only.
- While there are 19 address lines on the CY14B104K (18 address lines on the CY14B104M), only 13 address lines (A<sub>14</sub>-A<sub>2</sub>) are used to control software modes. The remaining address lines are don't care.
- The six consecutive address locations must be in the order listed. WE must be HIGH during all six cycles to enable a nonvolatile cycle.

The CY14B104K/CY14B104M protects data from corruption during low-voltage conditions by inhibiting all externally initiated STORE and write operations. The low-voltage condition is detected when  $V_{CC}$  is less than  $V_{SWITCH}$ . If the CY14B104K/CY14B104M is in a write mode (both CE and WE are LOW) at power-up, after a RECALL or STORE, the write is inhibited until the SRAM is enabled after t<sub>LZHSB</sub> (HSB to output active). This protects against inadvertent writes during power-up or brown out conditions.

## Real Time Clock Operation

### nvTIME Operation

The CY14B104K/CY14B104M offers internal registers that contain clock, alarm, watchdog, interrupt, and control functions. RTC registers use the last 16 address locations of the SRAM. Internal double buffering of the clock and timer information registers prevents accessing transitional internal clock data during a read or write operation. Double buffering also circumvents disrupting normal timing counts or the clock acturacy of the internal clock when accessing clock data. Clock and alarm registers store data in BCD format.

RTC functionality is described with respect to CY14B104K in the following sections. The same description applies to CY14B104M, except for the RTC register addresses. The RTC register addresses for CY14B104K range from 0x7FFF0 to 0x7FFFF, while those for CY14B104M range from 0x3FFF0 to 0x3FFFF. Refer to Table 3 on page 12 and Table 4 on page 13 for a detailed Register Map description.

### **Clock Operations**

The clock registers maintain time up to 9,999 years in one-second increments. The time can be set to any calendar time and the clock automatically keeps track of days of the week and month, leap years, and century transitions. There are eight registers dedicated to the clock functions, which are used to set time with a write cycle and to read time with a read cycle. These registers contain the time of day in BCD format. Bits defined as '0' are currently not used and are reserved for future use by Cypress.

### Reading the Clock

The double buffered RTC register structure reduces the chance of reading incorrect data from the clock. Internal updates to the CY14B104K time keeping registers are stopped when the read bit 'R' (in the Flags register at 0x7FFF0) is set to '1' before reading clock data to prevent reading of data in transition. Stopping the register updates does not affect clock accuracy.

When a read sequence of RTC device is initiated, the update of the user timekeeping registers stops and does not restart until a '0' is written to the read bit 'R' (in the Flags register at 0x7FFF0). After the end of read sequence, all the RTC registers are simultaneously updated within 20 ms.

### Setting the Clock

A write access to the RTC device stops updates to the time keeping registers and enables the time to be set when the write bit 'W' (in the Flags register at 0x7FFF0) is set to '1'. The correct day, date, and time is then written into the registers and must be

in 24 hour BCD format. The time written is referred to as the "Base Time". This value is stored in nonvolatile registers and used in the calculation of the current time. When the write bit 'W' is cleared by writing '0' to it, the values of timekeeping registers are transferred to the actual clock counters after which the clock resumes normal operation.

If the time written to the timekeeping registers is not in the correct BCD format, each invalid nibble of the RTC registers continue counting to 0xF before rolling over to 0x0 after which RTC resumes normal operation.

**Note** After 'W' bit is set to '0', values written into the timekeeping, alarm, calibration, and interrupt registers are transferred to the RTC time keeping counters in  $t_{RTCp}$  time. These counter values must be saved to nonvolatile memory either by initiating a Software/Hardware STORE or AutoStore operation. While working in AutoStore disabled mode, perform a STORE operation after  $t_{RTCp}$  time while writing into the RTC registers for the modifications to be correctly recorded.

#### **Backup Power**

The RTC in the CY14B104K is intended for permanently powered operation. The V<sub>RTCcap</sub> or V<sub>RTCbat</sub> pin is connected depending on whether a capacitor or battery is chosen for the application. When the primary power, V<sub>CC</sub>, fails and drops below V<sub>SWITCH</sub> the device switches to the backup power supply.

The clock oscillator uses very little current, which maximizes the backup time available from the backup source. Regardless of the clock operation with the primary source removed, the data stored in the nvSRAM is secure, having been stored in the nonvolatile elements when power was lost.

During backup operation, the CY14B104K consumes a  $0.35 \,\mu$ A (Typ) at room temperature. The user must choose capacitor or battery values according to the application.

**Note**: If a battery is applied to V<sub>RTCbat</sub> pin prior to V<sub>CC</sub>, the chip will draw high I<sub>BAK</sub> current. This occurs even if the oscillator is disabled. In order to maximize battery life, V<sub>CC</sub> must be applied before a battery is applied to V<sub>RTCbat</sub> pin.

Backup time values based on maximum current specifications are shown in the following Table 2. Nominal backup times are approximately two times longer.

| Capacitor Value | Backup Time |
|-----------------|-------------|
| 0.1 F           | 72 hours    |
| 0.47 F          | 14 days     |
| 1.0 F           | 30 days     |

Using a capacitor has the obvious advantage of recharging the backup source each time the system is powered up. If a battery is used, a 3 V lithium is recommended and the CY14B104K sources current only from the battery when the primary power is removed. However the battery is not recharged at any time by the CY14B104K. The battery capacity must be chosen for total anticipated cumulative down time required over the life of the system.

### Stopping and Starting the Oscillator

The OSCEN bit in the calibration register at 0x7FFF8 controls the enable and disable of the oscillator. This bit is nonvolatile and is shipped to customers in the "enabled" (set to '0') state. To preserve the battery life when the system is in storage, OSCEN must be set to '1'. This turns off the oscillator circuit, extending the battery life. If the OSCEN bit goes from disabled to enabled, it takes approximately one second (two seconds maximum) for the oscillator to start.

While system power is off, if the voltage on the backup supply ( $V_{RTCcap}$  or  $V_{RTCbat}$ ) falls below their respective minimum level, the oscillator may fail. The CY14B104K has the ability to detect oscillator failure when system power is restored. This is recorded in the Oscillator Fail Flag (OSCF) of the Flags register at the address 0x7FFF0. When the device is powered on ( $V_{CC}$  goes above  $V_{SWITCH}$ ) the OSCEN bit is checked for the 'enabled' status. If the OSCEN bit is enabled and the oscillator is not active within the first 5 ms, the OSCF bit is set to '1'. The system must check for this condition and then write '0' to clear the flag.

Note that in addition to setting the OSCF flag bit, the time registers are reset to the 'Base Time', which is the value last written to the timekeeping registers. The control or calibration registers and the OSCEN bit are not affected by the 'oscillator failed' condition.

The value of OSCF must be reset to '0' when the time registers are written for the first time. This initializes the state of this bit which may have become set when the system was first powered on.

To reset OSCF, set the write bit 'W' (in the Flags register at 0x7FFF0) to a '1' to enable writes to the Flags register. Write a '0' to the OSCF bit and then reset the write bit to '0' to disable writes.

### Calibrating the Clock

The RTC is driven by a quartz controlled crystal with a nominal frequency of 32.768 kHz. Clock accuracy depends on the quality of the crystal and calibration. The crystals available in market typically have an error of  $\pm$ 20 ppm to  $\pm$ 35 ppm. However, CY14B104K employs a calibration circuit that improves the accuracy to +1/–2 ppm at 25 °C. This implies an error of +2.5 seconds to –5 seconds per month.

The calibration circuit adds or subtracts counts from the oscillator divider circuit to achieve this accuracy. The number of pulses that are suppressed (subtracted, negative calibration) or split (added, positive calibration) depends upon the value loaded into the five calibration bits found in Calibration register at 0x7FFF8. The calibration bits occupy the five lower order bits in the Calibration register. These bits are set to represent any value between '0' and 31 in binary form. Bit D5 is a sign bit, where a '1' indicates positive calibration and a '0' indicates negative calibration. Adding counts speeds the clock up and subtracting counts slows the clock down. If a binary '1' is loaded into the register, it corresponds to an adjustment of 4.068 or -2.034 ppm offset in oscillator error, depending on the sign.

Calibration occurs within a 64-minute cycle. The first 62 minutes in the cycle may, once every minute, have one second shortened by 128 or lengthened by 256 oscillator cycles. If a binary '1' is loaded into the register, only the first two minutes of the 64-minute cycle are modified. If a binary 6 is loaded, the first 12 are affected, and so on. Therefore, each calibration step has the effect of adding 512 or subtracting 256 oscillator cycles for every 125,829,120 actual oscillator cycles, that is, 4.068 or -2.034 ppm of adjustment per calibration step in the Calibration register.

To determine the required calibration, the CAL bit in the Flags register (0x7FFF0) must be set to '1'. This causes the INT pin to toggle at a nominal frequency of 512 Hz. Any deviation measured from the 512 Hz indicates the degree and direction of the required correction. For example, a reading of 512.01024 Hz indicates a +20 ppm error. Hence, a decimal value of -10 (001010b) must be loaded into the Calibration register to offset this error.

**Note** Setting or changing the Calibration register does not affect the test output frequency.

To set or clear CAL, set the write bit 'W' (in the Flags register at 0x7FFF0) to '1' to enable writes to the Flags register. Write a value to CAL, and then reset the write bit to '0' to disable writes.

#### Alarm

The alarm function compares user programmed values of alarm time and date (stored in the registers 0x7FFF1-5) with the corresponding time of day and date values. When a match occurs, the alarm internal flag (AF) is set and an interrupt is generated on INT pin if Alarm Interrupt Enable (AIE) bit is set.

There are four alarm match fields – date, hours, minutes, and seconds. Each of these fields has a match bit that is used to determine if the field is used in the alarm match logic. Setting the match bit to '0' indicates that the corresponding field is used in the match process. Depending on the match bits, the alarm occurs as specifically as once a month or as frequently as once every minute. Selecting none of the match bits (all 1s) indicates that no match bits (all 0s) causes an exact time and date match.

There are two ways to detect an alarm event: by reading the AF flag or monitoring the INT pin. The AF flag in the Flags register at 0x7FFF0 indicates that a date or time match has occurred. The AF bit is set to '1' when a match occurs. Reading the Flags register clears the alarm flag bit (and all others). A hardware interrupt pin may also be used to detect an alarm event.

To set, clear or enable an alarm, set the 'W' bit (in Flags Register - 0x7FFF0) to '1' to enable writes to Alarm Registers. After writing the alarm value, clear the 'W' bit back to '0' for the changes to take effect.

**Note** CY14B104K requires the alarm match bit for seconds (bit 'D7' in Alarm-Seconds register 0x7FFF2) to be set to '0' for proper operation of Alarm Flag and Interrupt.

### Watchdog Timer

The watchdog timer is a free running down counter that uses the 32-Hz clock (31.25 ms) derived from the crystal oscillator. The oscillator must be running for the watchdog to function. It begins counting down from the value loaded in the watchdog timer register.

The timer consists of a loadable register and a free running counter. On power-up, the watchdog time out value in register 0x7FFF7 is loaded into the counter load register. Counting begins on power-up and restarts from the loadable value any time the watchdog strobe (WDS) bit is set to '1'. The counter is compared to the terminal value of '0'. If the counter reaches this value, it causes an internal flag and an optional interrupt output.

You can prevent the time out interrupt by setting WDS bit to '1' prior to the counter reaching '0'. This causes the counter to reload with the watchdog time out value and to be restarted. As long as the user sets the WDS bit prior to the counter reaching the terminal value, the interrupt and WDT flag never occur.

New time out values are written by setting the watchdog write bit to '0'. When the WDW is '0', new writes to the watchdog time out value bits D5–D0 are enabled to modify the time out value. When WDW is '1', writes to bits D5–D0 are ignored. The WDW function enables a user to set the WDS bit without concern that the watchdog timer value is modified. A logical diagram of the watchdog timer is shown in Figure 3. Note that setting the watchdog time out value to '0' disables the watchdog function.

The output of the watchdog timer is the flag bit WDF that is set if the watchdog is allowed to time out. If the watchdog interrupt enable (WIE) bit in the interrupt register is set, a hardware interrupt on INT pin is also generated on watchdog timeout. The flag and the hardware interrupt are both cleared when user reads the flags registers.

### **Power Monitor**

The CY14B104K provides a power management scheme with power fail interrupt capability. It also controls the internal switch to backup power for the clock and protects the memory from low  $V_{CC}$  access. The power monitor is based on an internal band gap reference circuit that compares the  $V_{CC}$  voltage to  $V_{SWITCH}$  threshold.

As described in the section AutoStore Operation on page 4, when V<sub>SWITCH</sub> is reached as V<sub>CC</sub> decays from power loss, a data STORE operation is initiated from SRAM to the nonvolatile elements, securing the last SRAM data state. Power is also switched from V<sub>CC</sub> to the backup supply (battery or capacitor) to operate the RTC oscillator.

When operating from the backup source, read and write operations to nvSRAM are inhibited and the RTC functions are not available to the user. The RTC clock continues to operate in the background. The updated RTC time keeping registers data are available to the user after  $V_{CC}$  is restored to the device (see AutoStore/Power-Up RECALL on page 22).

#### Interrupts

The CY14B104K has flags register, interrupt register, and interrupt logic that can signal interrupt to the microcontroller. There are three potential sources for interrupt: watchdog timer, power monitor, and alarm timer. Each of these can be individually enabled to drive the INT pin by appropriate setting in the Interrupt register (0x7FFF6). In addition, each has an associated flag bit in the flags register (0x7FFF0) that the host processor uses to determine the cause of the interrupt. The INT pin driver has two bits that specify its behavior when an interrupt occurs.

An interrupt is raised only if both a flag is raised by one of the three sources and the respective interrupt enable bit in interrupts register is enabled (set to '1'). After an interrupt source is active, two programmable bits, H/L and P/L, determine the behavior of the output pin driver on INT pin. These two bits are located in the interrupt register and can be used to drive level or pulse mode output from the INT pin. In pulse mode, the pulse width is internally fixed at approximately 200 ms. This mode is intended to reset a host microcontroller. In the level mode, the pin goes to its active polarity until the flags register is read by the user. This mode is used as an interrupt to a host microcontroller. The control bits are summarized in the following section.

Interrupts are only generated while working on normal power and are not triggered when system is running in backup power mode.

**Note** CY14B104K generates valid interrupts only after the Power-up RECALL sequence is completed. All events on INT pin must be ignored for  $t_{HRECALL}$  duration after powerup.

#### Interrupt Register

**Watchdog Interrupt Enable (WIE)**: When set to '1', the watchdog timer drives the INT pin and an internal flag when a watchdog time out occurs. When WIE is set to '0', the watchdog timer only affects the WDF flag in flags register.

Alarm Interrupt Enable (AIE): When set to '1', the alarm match drives the INT pin and an internal flag. When AIE is set to '0', the alarm match only affects the AF flag in flags register.

**Power Fail Interrupt Enable (PFE)**: When set to '1', the power fail monitor drives the pin and an internal flag. When PFE is set to '0', the power fail monitor only affects the PF flag in flags register.

**High/Low (H/L)**: When set to a '1', the INT pin is active HIGH and the driver mode is push pull. The INT pin drives HIGH only when  $V_{CC}$  is greater than  $V_{SWITCH}$ . When set to a '0', the INT pin is active LOW and the drive mode is open drain. The INT pin must be pulled up to Vcc by a 10 k resistor while using the interrupt in active LOW mode.

**Pulse/Level (P/L)**: When set to a '1' and an interrupt occurs, the INT pin is driven for approximately 200 ms. When P/L is set to a '0', the INT pin is driven HIGH or LOW (determined by H/L) until the flags register is read.

When an enabled interrupt source activates the INT pin, an external host reads the flags registers to determine the cause. Remember that all flags are cleared when the register is read. If the INT pin is programmed for Level mode, then the condition clears and the INT pin returns to its inactive state. If the pin is programmed for pulse mode, then reading the flag also clears the flag and the pin. The pulse does not complete its specified duration if the flags register is read. If the INT pin is used as a host reset, the flags register is not read during a reset.

### **Flags Register**

The flags register has three flag bits: WDF, AF, and PF, which can be used to generate an interrupt. These flags are set by the watchdog timeout, alarm match, or power fail monitor respectively. The processor can either poll this register or enable interrupts when a flag is set. These flags are automatically reset when the register is read. The flags register is automatically loaded with the value 0x00 on power-up (except for the OSCF bit. See Stopping and Starting the Oscillator on page 8).

### **RTC External Components**

The RTC requires connecting an external 32.768 kHz crystal and  $C_1$ ,  $C_2$  load capacitance as shown in the Figure 5. The figure shows the recommnded RTC external component values. The load capacitances  $C_1$  and  $C_2$  are inclusive of parasitic of the printed circuit board (PCB). The PCB parasitic includes the capacitance due to land pattern of crystal pads/pins,  $X_{in}/X_{out}$  pads and copper traces connecting crystal and device pins.

Recommended Values  $Y_1 = 32.768 \text{ kHz} (12.5 \text{ pF})$   $C_1 = 12 \text{ pF}$  $C_2 = 69 \text{ pF}$ 

Note The recommended values for C1 and C2 include board trace capacitance.

#### Note

10. For nonvolatile static random access memory (nvSRAM) real time clock (RTC) design guidelines and best practices, see application note AN61546.

## PCB Design Considerations for RTC

RTC crystal oscillator is a low current circuit with high impedance nodes on their crystal pins. Due to lower timekeeping current of RTC, the crystal connections are very sensitive to noise on the board. Hence it is necessary to isolate the RTC circuit from other signals on the board.

It is also critical to minimize the stray capacitance on the PCB. Stray capacitances add to the overall crystal load capacitance and therefore cause oscillation frequency errors. Proper bypassing and careful layout are required to achieve the optimum RTC performance.

#### Layout requirements

The board layout must adhere to (but not limited to) the following guidelines during routing RTC circuitry. Following these guidelines help you achieve optimum performance from the RTC design.

It is important to place the crystal as close as possible to the X<sub>in</sub> and X<sub>out</sub> pins. Keep the trace lengths between the crystal and RTC equal in length and as short as possible to reduce the probability of noise coupling by reducing the length of the antenna.

- Keep X<sub>in</sub> and X<sub>out</sub> trace width lesser than 8 mils. Wider trace width leads to larger trace capacitance. The larger these bond pads and traces are, the more likely it is that noise can couple from adjacent signals.
- Shield the X<sub>in</sub> and X<sub>out</sub> signals by providing a guard ring around the crystal circuitry. This guard ring prevents noise coupling from neighboring signals.
- Take care while routing any other high speed signal in the vicinity of RTC traces. The more the crystal is isolated from other signals on the board, the less likely it is that noise is coupled into the crystal. Maintain a minimum of 200 mil separation between the X<sub>in</sub>, X<sub>out</sub> traces and any other high speed signal on the board.
- No signals should run underneath crystal components on the same PCB layer.
- Create an isolated solid copper plane on adjacent PCB layer and underneath the crystal circuitry to prevent unwanted noise coupled from traces routed on the other signal layers of the PCB. The local plane should be separated by at least 40 mils from the neighboring plane on the same PCB layer. The solid plane should be in the vicinity of RTC components only and its perimeter should be kept equal to the guard ring perimeter. Figure 6 shows the recommended layout for RTC circuit.

Figure 6. Recommended Layout for RTC

Notes

11. Upper byte D<sub>15</sub>–D<sub>8</sub> (CY14B104M) of RTC registers are reserved for future use. 12. ( ) designates values shipped from the factory.

This is a binary value, not a BCD value.
 This is a binary value, not a BCD value.
 When user resets OSCF flag bit, the flags register will be updated after t<sub>RTCp</sub> time.

| WE                              | W         | (D5–D0). T<br>Setting this  | Watchdog write enable. Setting this bit to 1 disables any WRITE to the watchdog timeout value (D5–D0). This allows the user to set the watchdog strobe bit without disturbing the timeout value. Setting this bit to 0 allows bits D5–D0 to be written to the watchdog register when the next write cycle is complete. This function is explained in more detail in Watchdog Timer on page 8. |   |                |               |                |               |               |  |
| WI                              | DT        | Watchdog timeout selection. The watchdog timer interval is selected by the 6-bit value in this register. It represents a multiplier of the 32 Hz count (31.25 ms). The range of timeout value is 31.25 ms (a setting of '1') to 2 seconds (setting of 3 Fh). Setting the watchdog timer register to '0' disables the timer. These bits can be written only if the WDW bit was set to 0 on a previous cycle. |   |   |                |               |                |               |               |  |
| 0x7FFF6                         | 0x3FFF6   | Interrupt Status/Control  |   |   |                |               |                |               |               |  |

 <sup>15.</sup> Typical values are at 25 °C, V<sub>CC</sub> = V<sub>CC(Typ)</sub>. Not 100% tested.
 16. The HSB pin has I<sub>OUT</sub> = -2 μA for V<sub>OH</sub> of 2.4 V when both active HIGH and LOW drivers are disabled. When they are enabled standard V<sub>OH</sub> and V<sub>OL</sub> are valid. This parameter is characterized but not tested.

### DC Electrical Characteristics (continued)

### Over the Operating Range

| Parameter                             | Description  | Test Conditions                    | Min | <b>Typ</b> <sup>[15]</sup> | Max             | Unit |
|---------------------------------------|--|------------------------------------|-----|----------------------------|-----------------|------|
| V <sub>CAP</sub> <sup>[17]</sup>      | Storage capacitor  | Between $V_{CAP}$ pin and $V_{SS}$ | 61  | 68                         | 180             | μF   |
| V <sub>VCAP</sub> <sup>[18, 19]</sup> | Maximum voltage driven on $V_{\mbox{CAP}}$ pin by the device | V <sub>CC</sub> = Max              | -   | _                          | V <sub>CC</sub> | V    |

### **Data Retention and Endurance**

Over the Operating Range

| Parameter         | Description                  | Min   | Unit  |
|-------------------|------------------------------|-------|-------|
| DATA <sub>R</sub> | Data retention               | 20    | Years |
| NV <sub>C</sub>   | Nonvolatile STORE operations | 1,000 | K     |

### Capacitance

| Parameter <sup>[19]</sup> | Description                                 | Test Conditions  | Max | Unit |
|---------------------------|---|--|-----|------|
| C <sub>IN</sub>           | Input capacitance (except BHE, BLE and HSB) | $T_A = 25 \text{ °C}, f = 1 \text{ MHz}, V_{CC} = V_{CC(Typ)}$ | 7   | pF   |
|                           | Input capacitance (for BHE, BLE and HSB)    |  | 8   | pF   |
| C <sub>OUT</sub>          | Output capacitance (except HSB)             |  | 7   | pF   |
|                           | Output capacitance (for HSB)                |  | 8   | pF   |

### **Thermal Resistance**

| Parameter <sup>[19]</sup> | Description                                 | Test Conditions   | 44-pin TSOP II | 54-pin TSOP II | Unit |
|---------------------------|---|---|----------------|----------------|------|
| $\Theta_{JA}$             | Thermal resistance<br>(junction to ambient) | Test conditions follow standard test methods and procedures for | 43.3           | 42.03          | °C/W |
| $\Theta^{JC}$             | Thermal resistance<br>(junction to case)    | measuring thermal impedance, in accordance with EIA/JESD51.     | 5.56           | 6.08           | °C/W |

Notes
 17. Min V<sub>CAP</sub> value guarantees that there is a sufficient charge available to complete a successful AutoStore operation. Max V<sub>CAP</sub> value guarantees that the capacitor on V<sub>CAP</sub> is charged to a minimum voltage during a Power-Up RECALL cycle so that an immediate power-down cycle can complete a successful AutoStore. Therefore it is always recommended to use a capacitor within the specified min and max limits. Refer application note AN43593 for more details on V<sub>CAP</sub> options.
 18. Maximum voltage on V<sub>CAP</sub> in (V<sub>VCAP</sub>) is provided for guidance when choosing the V<sub>CAP</sub> capacitor. The voltage rating of the V<sub>CAP</sub> capacitor across the operating temperature range should be higher than the V<sub>VCAP</sub> voltage.
 19. These parameters are guaranteed by design and are not tested.

## **AC Test Loads**

Figure 7. AC Test Loads

## **AC Test Conditions**

| Input pulse levels                       | 0 V to 3 V       |
|--|------------------|
| Input rise and fall times (10%–90%)      | <u>&lt;</u> 3 ns |
| Input and output timing reference levels | 1.5 V            |

# **Switching Waveforms**

- Notes
  23. Test conditions assume signal transition time of 3 ns or less, timing reference levels of V<sub>CC</sub>/2, input pulse levels of 0 to V<sub>CC(typ)</sub>, and output loading of the specified lou/l<sub>OH</sub> and load capacitance shown in Figure 7 on page 18.
  24. WE must be HIGH during SRAM read cycles.
  25. Device is continuously selected with CE, OE and BHE / BLE LOW.
  26. These parameters are only guaranteed by design and are not tested.
  27. Measured ±200 mV from steady state output voltage.
  28. If WE is LOW when CE goes LOW, the outputs remain in the high impedance state.
  29. HSB must remain HIGH during read and write cycles.

### Switching Waveforms (continued)

Figure 9. SRAM Read Cycle 2 (CE and OE Controlled) <sup>[30, 31, 32]</sup>

- Notes

   30. <u>BHE</u> and <u>BLE</u> are applicable for × 16 configuration only.

   31. <u>WE</u> must be HIGH during SRAM read cycles.

   32. <u>HSB</u> must remain HIGH during read and write cycles.

   33. <u>If WE is LOW</u> when CE goes LOW, the outputs remain in the high impedance state.

   34. CE or WE must be  $\geq$  V<sub>IH</sub> during address transitions.

### Switching Waveforms (continued)

Figure 11. SRAM Write Cycle 2 (CE Controlled) <sup>[35, 36, 37, 38]</sup>

Figure 12. SRAM Write Cycle 3 (BHE and BLE Controlled) <sup>[36, 37, 38, 39, 40]</sup>

### (Not applicable for RTC register writes)

- BHE and BLE are applicable for × 16 configuration only.
   If WE is LOW when CE goes LOW, the outputs remain in the high impedance state.
- 37. HSB must remain HIGH during read and write cycles.
- 38.  $\overline{\text{CE}}$  or  $\overline{\text{WE}}$  must be  $\geq V_{IH}$  during address transitions.
- 39. While there are 19 address lines on the CY14B104K (18 address lines on the CY14B104M), only 13 address lines (A14-A2) are used to control software modes. The remaining address lines are don't care. 40. Only  $\overline{CE}$  and  $\overline{WE}$  controlled writes to RTC registers are allowed.  $\overline{BLE}$  pin must be held LOW before  $\overline{CE}$  or  $\overline{WE}$  pin goes LOW for writes to RTC register.

## AutoStore/Power-Up RECALL

### Over the Operating Range

| Parameter                            | Description                               | CY14B104K | Unit   |    |  |

# Switching Waveforms – AutoStore/Power-up RECALL

- 41. t<sub>HRECALL</sub> starts from the time V<sub>CC</sub> rises above V<sub>SWITCH</sub>.
   42. If an SRAM write has not taken place since the last nonvolatile cycle, no AutoStore or Hardware STORE takes place.
- 43. On a Hardware STORE and AutoStore initiation, SRAM write operation continues to be enabled for time t<sub>DELAY</sub>.

- 44. These parameters are only guaranteed by design and are not tested. 45. Read and write cycles are ignored <u>during</u> STORE, REC<u>ALL</u>, and while  $V_{CC}$  is below  $V_{SWITCH}$ . 46. During power-up and power-down, HSB glitches when HSB pin is pulled up through an external resistor.

# Software Controlled STORE and RECALL Cycle

#### Over the Operating Range

| Parameter <sup>[47, 48]</sup>       | Description                        | 25  | ns  | 45  | Unit |     |

| t <sub>SS</sub> <sup>[49, 50]</sup> | Soft sequence processing time      | _   | 100 | _   | 100  | μS  |

## Switching Waveforms – Software Controlled STORE/RECALL Cycle

Figure 14. CE and OE Controlled Software STORE and RECALL Cycle [48]

#### Notes

47. The software sequence is clocked with CE controlled or OE controlled reads.

48. The six consecutive addresses must be read in the order listed in Table 1. WE must be HIGH during all six consecutive cycles.

- 49. This is the amount of time it takes to take action on a soft sequence command.  $V_{CC}$  power must remain HIGH to effectively register command. 50. Commands such as STORE and RECALL lock out I/O until operation is complete which further increases this time. See the specific command. 51. DQ output data at the sixth read may be invalid since the output is disabled at  $t_{DELAY}$  time.

# Hardware STORE Cycle

### Over the Operating Range

| Parameter         | Description  | CY14B104K | Unit |      |
|-------------------|--|-----------|------|------|
| i arameter        | Description  | Min       | Мах  | Onit |
| t <sub>DHSB</sub> | HSB to output active time when write latch not set | _         | 25   | ns   |
| t <sub>PHSB</sub> | Hardware STORE pulse width                         | 15        | _    | ns   |

Figure 16. Hardware STORE Cycle <sup>[52]</sup>

## Switching Waveforms – Hardware STORE Cycle

- 52. If an SRAM write has not taken place since the last nonvolatile cycle, no AutoStore or Hardware STORE takes place.
- 53. This is the amount of time it takes to take action on a soft sequence command. V<sub>CC</sub> power must remain HIGH to effectively register command.

# **Truth Table For SRAM Operations**

HSB should remain HIGH for SRAM Operations.

### Table 5. Truth Table for × 8 Configuration

| CE | WE | OE | Inputs and Outputs <sup>[55]</sup>           | Mode                | Power   |
