

CYIL2SM1300AA

LUPA 1300-2: High Speed CMOS Image Sensor

Features

- 1280 x 1024 Active Pixels
- 14 μm X 14 μm Square Pixels
- 1" Optical Format
- Monochrome or Color Digital Output
- 500 fps Frame Rate
- On-Chip 10-Bit ADCs
- 12 LVDS Serial Outputs
- Random Programmable ROI Readout
- Pipelined and Triggered Snapshot Shutter
- On-Chip Column FPN Correction
- Serial to Parallel Interface (SPI)
- Limited Supplies: Nominal 2.5V and 3.3V
- 0°C to 70°C Operational Temperature Range
- 168-Pin μPGA Package
- Power Dissipation: 1350 mW

Applications

- High Speed Machine Vision
- Motion Analysis
- Intelligent Traffic System
- Medical Imaging
- Industrial Imaging

Description

The LUPA 1300-2 is an integrated SXGA high speed, high sensitivity CMOS image sensor. This sensor targets high speed machine vision and industrial monitoring applications. The LUPA 1300-2 sensor runs at 500 fps and has triggered and pipelined shutter modes. It packs 24 parallel 10-bit A/D converters with an aggregate conversion rate of 740 MSPS. On-chip digital column FPN correction enables the sensor to output ready to use image data for most applications. To enable simple and reliable system integration, the 12 channels, 1 sync channel, 8 Gbps, and LVDS serial link protocol supports skew correction and serial link integrity monitoring.

The peak responsivity of the 14 μm x 14 μm 6T pixel is 7350 V.m2/W.s. Dynamic range is measured at 57 dB. In full frame video mode, the sensor consumes 1350 mW from the 2.5V power supply. The sensors integrate A/D conversion, on-chip timing for a wide range of operating modes, and has an LVDS interface for easy system integration.

By removing the visually disturbing column patterned noise, this sensor enables building a camera without any offline correction or the need for memory. In addition, the on-chip column FPN correction is more reliable than an offline correction, because it compensates for supply and temperature variations. The sensor requires one master clock for operations up to 500 fps.

The LUPA 1300-2 is housed in a 168 pin μPGA package and is available in a monochrome version and Bayer (RGB) patterned color filter array. The monochrome version is available without glass. Contact your local Cypress office.

Table 1. Marketing Part Number

Marketing Part Number (ES Samples)	Mono/Color	Package
CYIL2SM1300AA-GZDC	mono with glass	168 pin ceramic μPGA
CYIL2SM1300AA-GWCES	mono without glass ^[1]	
CYIL2SC1300AA-GZDC	color with glass	

Note

1. Contact your local sales office for the windowless option.

Overview

This data sheet describes the interface of the LUPA1300-2 image sensor. The SXGA resolution CMOS active pixel sensor features synchronous shutter and a maximal frame rate of 500 fps in full resolution. The readout speed is boosted by sub sampling and the windowed region of interest (ROI) readout. FPN correction cannot be used in conjunction with sub-sampling and windowed region of interest readout. High dynamic range scenes can be captured using the double and multiple slope functionality. User programmable row and column start and stop positions enables windowing. Sub sampling reduces resolution while maintaining the constant field of view and an increased frame rate.

The LUPA1300-2 sensor has 12 LVDS high speed outputs that transfer image data over longer distances. This simplifies the surrounding system. The LVDS interface can receive high speed and wide bandwidth data signals and maintain low noise and distortion. A special training mode enables the receiving system to synchronize the coming data stream when switching to master, slave, or triggered mode. The image sensor also integrates a programmable offset and gain amplifier for each channel.

A 10-bit ADC converts the analog data to a 10-bit digital word stream. The sensor uses a 3-wire Serial-Parallel Interface (SPI). It requires only one master clock for operation up to 500 fps.

The sensor is available in a monochrome version or Bayer (RGB) patterned color filter array. It is placed in a 168-pin ceramic μ PGA package.

Specifications

Table 2. General Specifications

Parameter	Specifications
Active Pixels	1280 (H) x 1024 (V)
Pixel Size	14 μ m x 14 μ m
Pixel Type	6T pixel architecture
Pixel Rate	630 Mbps per channel (12 serial LVDS outputs)
Shutter Type	Pipelined and Triggered Global Shutter
Frame Rate	500 fps at 1.3 Mpixel (boosted by subsampling and windowing)
Master Clock	315 MHz for 500 fps
Windowing (ROI)	Randomly programmable ROI read out up to four multiple windows
Read Out	Windowed, flipped, mirrored, and subsampled read out possible
ADC Resolution	10-bit, on-chip
Sensitivity	10.16 V/lux.s at 550 nm
Extended Dynamic Range	Multiple slope (up to 90 dB optical dynamic range)

Table 3. Electro Optical Specifications

Parameter	Value
Conversion gain	34 μ V/e ⁻
Full well charge	30000e ⁻
Responsivity	7350 V.m ² /W.s at 680 nm
Fill factor	40%
Parasitic light sensitivity	< 1/10000
Dark noise	37e ⁻
QE x FF	35% at 680 nm
FPN	2% rms of the output swing
PRNU	<1% rms of the output signal
Dark signal	170 mV/s at 30°C
Power dissipation	1350 mW

Photovoltaic Response Curve

Spectral Response Curve

Figure 3. Spectral Response of LUPA 1300-2

Figure 4. Spectral Response of LUPA 1300-2 Color Sensor

Electrical Specifications

Exceeding maximum ratings may shorten the useful life of the device. User guidelines are not tested.

Table 4. Absolute Ratings [2]

Symbol	Parameter	Min	Max	Units
V _{DIG}	Core digital supply voltage	-0.5	5.5	V
V _{IN}	Analog supply voltage	-0.5	5.5	V
I _{IO}	DC supply current			mA
ESD: HBM	Human Body Model	2000		V
ESD: CDM	Charged Device Model	500		V
T _J	Temperature range	0	70	°C

Table 5. Power Supply Ratings [3, 4, 5]

Boldface limits apply for T_A=T_{MIN} to T_{MAX}, all other limits T_A=+25°C. Clock = 315 MHz

Symbol	Power Supply	Parameter	Condition	Min	Typ	Max	Units
V _{ANA} , GND _{ANA}	Analog Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		7	20	mA
		Peak Current	Clock enabled, lux=0		16		mA
		Standby current	Shutdown mode, lux=0		1		mA
V _{DIG} , GND _{DIG}	Digital Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		80	120	mA
		Peak Current	Clock enabled, lux=0		130		
		Standby current	Shutdown mode, lux=0		52		mA
V _{PIX} , GND _{PIX}	Pixel Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		6	50	mA
		Peak Current during FOT	Clock enabled, lux=0, transient duration=9 μs		1.4		A
		Peak Current during ROT	Clock enabled, lux=0, transient duration=2.5 μs		35		mA
		Standby current	Shutdown mode, lux=0		1		mA
V _{LVDS} , GND _{LVDS}	LVDS Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		220	275	mA
		Peak current	Clock enabled, lux=0		280		mA
		Standby current	Shutdown mode, lux=0		100		mA
V _{ADC} , GND _{ADC}	ADC Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		210	275	mA
		Peak Current	Clock enabled, lux=0		260		mA
		Standby current	Shutdown mode, lux=0		3		mA
V _{BUF} , GND _{BUF}	Buffer Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		30	50	mA
		Peak Current	Clock enabled, lux=0		85		mA
		Standby current	shutdown mode, lux=0		0.1		mA

Notes

- Absolute ratings are those values beyond which damage to the device may occur.
- All parameters are characterized for DC conditions after thermal equilibrium is established.
- Peak currents were measured without the load capacitor from the LDO (Low Dropout Regulator). The 100 nF capacitor bank was connected to the pin in question.
- This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields. However, it is recommended that normal precautions be taken to avoid application of any voltages higher than the maximum rated voltages to this high impedance circuit.

Table 5. Power Supply Ratings [3, 4, 5] (continued)

Boldface limits apply for $T_A=T_{MIN}$ to T_{MAX} , all other limits $T_A=+25^{\circ}C$. Clock = 315 MHz

Symbol	Power Supply	Parameter	Condition	Min	Typ	Max	Units
V_{SAMPLE}, GND_{SAMPLE}	Sampling Circuitry Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		2		mA
		Peak Current	Clock enabled, lux=0		42		mA
		Standby current	Shutdown mode, lux=0		1		mA
V_{RES}	Reset Supply	Operating voltage		-5%	3.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		2	15	mA
		Peak Current	Clock enabled, lux=0		65		mA
		Standby current	Shutdown mode, lux=0		2		mA
V_{RES_AB}	Antiblooming Supply	Operating voltage		-10%	0.7	+10%	V
		Dynamic Current	Clock enabled, lux=0		1		mA
		Peak Current following edge reset	Clock enabled, lux=0		50		mA
		Standby current	Shutdown mode, lux=0		1		mA
V_{RES_DS}	Reset Dual Slope Supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		0.4	3	mA
		Peak Current	Clock enabled, lux=0		36		mA
V_{RES_TS}	Reset Triple Slope Supply	Operating voltage		-5%	1.8	+5%	V
		Dynamic Current	Clock enabled, lux=0		0.3	2	mA
		Peak Current	Clock enabled, lux=0		14		mA
V_{MEM_L}	Memory Element low level supply	Operating voltage		-5%	2.5	+5%	V
		Dynamic Current	Clock enabled, lux=0		0.2	1	mA
		Peak Current during FOT	Clock enabled, lux=0		62		mA
		Peak Current during FOT	Clock enabled, bright		30		mA
V_{MEM_H}	Memory Element high level supply	Operating voltage		-5%	3.3	+5%	V
		Dynamic Current	Clock enabled, lux=0		1		mA
		Peak Current during FOT	Clock enabled, lux=0		45		mA
V_{PRECH}	Pre_charge Driver Supply	Operating voltage		-10%	0.7	+10%	V
		Dynamic Current	Clock enabled, lux=0		0.3	3	mA
		Peak Current during FOT	Clock enabled, lux=0		32		mA
		Peak Current during FOT	Clock enabled, lux=bright		25		mA

Every module in the image sensor has its own power supply and ground. The grounds can be combined externally, but not all power supply inputs may be combined. Some power supplies must be isolated to reduce electrical crosstalk and improve shielding, dynamic range, and output swing. Internal to the image sensor, the ground lines of each module are kept separate to improve shielding and electrical crosstalk between them.

The LUPA 1300-2 contains circuitry to protect the inputs against damage due to high static voltages or electric fields. However, take normal precautions to avoid voltages higher than the maximum rated voltages in this high impedance circuit. Unused

inputs must always be tied to an appropriate logic level, for example, V_{DD} or GND. All cap_XXX pins must be connected to ground through a 100 nF capacitor.

The recommended combinations of supplies are:

- Analog group of +2.5V supply: $V_{SAMPLE}, V_{RES_DS}, V_{MEM_L}, V_{ADC}, V_{pix}, V_{ANA}, V_{BUF}$
- Digital Group of +2.5V supply: V_{DIG}, V_{LVDS}

Table 6. Power Dissipation ^[3]

These specifications apply for $V_{DD} = 2.5V$, Clock = 315 MHz, 500 fps

Symbol	Parameter	Condition	Typ	Units
PDOWN	Power down	no clock running	400	mW
Power	Average Power Dissipation	lux = 0	1350	mW

Table 7. AC Electrical Characteristics ^[3]

The following specifications apply for $V_{DD} = 2.5V$, Clock = 315 MHz, 500 fps.

Symbol	Parameter	Condition	Typ	Max	Units
F_{CLK}	Input Clock Frequency	fps = 500		315	MHz
DC_{CLK}	Clock Duty Cycle	At maximum clock	50		%
fps	Frame rate	Maximum clock speed		500	fps

Sensor Architecture

The floor plan of the architecture is shown in Figure 5. The sensor consists of a pixel array, analog front end, data block, and LVDS transmitters and receivers. Separate modules for the SPI, clock division, and sequencer are also integrated. The image sensor of 1280 x 1024 pixels is read out in progressive scan.

This architecture enables programmable addressing in the x-direction in steps of 24 pixels, and in the y-direction in steps of one pixel. The starting point of the address can be uploaded by the serial parallel interface (SPI).

The AFE prepares the signal for the digital data block when the data is multiplexed and prepared for the LVDS interface.

Figure 5. Floor Plan of the Sensor

The 6T Pixel

To obtain the global shutter feature combined with a high sensitivity and good parasitic light sensitivity (PLS), implement the pixel architecture shown in [Figure 6](#). This pixel architecture is designed in a 14 µm x 14 µm pixel pitch. The pixel is designed to meet the specifications listed in [Table 2](#) and [Table 3](#) on page 2. This architecture also enables pipelined or triggered mode, as shown in [Figure 6](#).

Figure 6. 6T Pixel Architecture

Frame Rate and Windowing

Frame Rate

The frame rate depends on the input clock, the frame overhead time (FOT), and the row overhead time (ROT). The frame period is calculated by:

$$\text{Frame period} = \text{FOT} + \text{Nr. Lines} * (\text{ROT} + \text{Nr. Pixels} * \text{clock period})$$

Table 8. Frame Rate Parameters

Parameter	Comment	Clarification
FOT	Frame Overhead Time	Programmable: Default 315 MHz granularity clock cycles (5 µs at 630 MHz)
ROT	Row Overhead Time	Programmable: Default 13 granularity clock cycles (206 ns at 630 MHz)
Nr. Lines	Number of lines read out each frame	
Nr. Pixels	Number of pixels read out each line	
Clock Period	1/63 MHz = 15.9 ns	Every channel works at 63 MHz → 12 channels result in 756 MHz data rate

Example

Readout of the full resolution at nominal speed (756 MHz pixel rate = 1.32 ns)

$$\text{Frame period} = 5 \mu\text{s} + (1025 * (206 \text{ ns} + 1.32 \text{ ns} * 1296)) = 1.97 \text{ ms} \Rightarrow 507 \text{ fps}$$

The real speed of the LUPA1300-2 is reduced to 500 fps, because overhead pixels are read out for black level calibration and other on board features.

Windowing

Windowing is easily achieved by SPI. The starting point of the x and y address and the window size can be uploaded. The minimum step size in the x-direction is 24 pixels (choose only multiples of 24 as start or stop addresses). The minimum step size in the y-direction is one line (every line can be addressed) in normal mode, and two lines in sub sampling mode.

The section [Sequencer](#) on page 10 discusses the use of registers to achieve the desired ROI.

Table 9. Typical Frame Rates for 630 MHz Clock

Image Resolution (X*Y)	Frame Rate (fps)	Frame Read Out Time (µs)
1296x1025	507	1970
640 x 512	1842	550
256 x 256	6933	146

Analog to Digital Converter

The sensor has 24 10-bit pipelined ADCs on board. The ADCs nominally operate at 31.5 Msamples/s.

Table 10. ADC Parameters

Parameter	Specification
Data rate	31.5 Msamples/s
Quantization	10 bit
DNL	Typ. < 1 DN
INL	Typ. < 1 DN

Programmable Gain Amplifiers

The PGAs amplify the signal before sending it to the ADCs.

The amplification inside the PGA is controlled by one SPI setting: afemode [5:3].

Six gain steps can be selected by the afemode<5:3> register.

[Table 11](#) lists the six gain settings. The unity gain selection of the PGA is done by the default afemode<5:3> setting.

Table 11. Gain Settings

afemode<5:3>	Gain
000	1
001	1.5
010	2
011	2.25
100	3
101	4

Operation and Signaling

Digital Signals

Depending on the operation mode (Master or Slave), the pixel array of the image sensor requires different digital control signals. The function of each signal is listed in this table.

Table 12. Overview of Digital Signals

Signal Name	I/O	Comments
MONITOR_1	Output	Output pin for integration timing, high during integration
MONITOR_2	Output	Output pin for dual slope integration timing, high during integration
MONITOR_3	Output	Output pin for triple slope integration timing, high during integration
INT_TIME_3	Input	Integration pin triple slope
INT_TIME_2	Input	Integration pin dual slope
INT_TIME_1	Input	Integration pin first slope
RESET_N	Input	Sequencer reset, active LOW
CLK	Input	System clock (630 MHz)
SPI_CS	Input	SPI chip select
SPI_CLK	Input	Clock of the SPI
SPI_IN	Input	Data line of the SPI, serial input
SPI_OUT	Output	Data line of the SPI, serial output

Synchronous Shutter

In a synchronous (snapshot or global) shutter, light integration occurs on all pixels in parallel, although subsequent readout is sequential. [Figure 7](#) shows the integration and readout sequence for the synchronous shutter. All pixels are light sensitive at the same period of time. The whole pixel core is reset simultaneously, and after the integration time, all pixel values are sampled together on the storage node inside each pixel. The pixel core is read out line by line after integration. Note that the integration and readout cycle can occur in parallel or in sequential mode (pipelined or triggered). Refer to the section [Image Sensor Timing and Readout](#) on page 18.

Figure 7. Synchronous Shutter Operation

Non Destructive Readout (NDR)

Figure 8. Principle of Non Destructive Readout

The sensor can also be read out in a nondestructive method. After a pixel is initially reset, it can be read multiple times, without being reset. You can record the initial reset level and all intermediate signals. High light levels saturate the pixels quickly, but a useful signal is obtained from the early samples. For low light levels, the later or latest samples must be used. Essentially, an active pixel array is read multiple times, and reset only once. The external system intelligence interprets the data. [Table 13](#) on page 10 summarizes the advantages and disadvantages of nondestructive readout.

Table 13. Advantages and Disadvantages of Non Destructive Readout

Advantages	Disadvantages
Low noise, because it is true CDS	System memory required to record the reset level and the intermediate samples
High sensitivity. The conversion capacitance is kept low.	Requires multiples readings of each pixel, so there is higher data throughput
High dynamic range. The results include signals for short and long integration times.	Requires system level digital calculations

Note that the amount of samples taken with one initial reset is programmable in the `nr_of_ndr_steps` register. If `nr_of_ndr_steps` is one, the sensor operates in the default method, that is one reset and one sample. This is called the disable nondestructive read out mode.

When `nr_of_ndr_steps` is two, there is one reset and two samples, and so on. In the slave mode, nothing changes on the protocol of the signals `int_time_*`. The sequencer suppresses the internal reset signal to the pixel array.

Sequencer

The sequencer generates the complete internal timing of the pixel array and the readout. The timing can be controlled by the user through the SPI register settings. The sequencer operates on the same clock as the data block. This is a division by 10 of the input clock (internally divided).

[Table 14](#) lists the internal registers. These registers are discussed in detail in the section [Detailed Description of Internal Registers](#) on page 15.

Table 14. Internal Registers

Block	Register Name	Address [6..0]	Field	Reset Value	Description
MBS (reserved)	Fix1	0	[7:0]	0x00	Reserved, fixed value
	Fix2	1	[7:0]	0xFF	Reserved, fixed value

Table 14. Internal Registers (continued)

Block	Register Name	Address [6..0]	Field	Reset Value	Description
Sequencer	seqmode1	56	[0]	0	Enables image capture
			[1]	1	'1': Master mode, integration timing is generated on-chip '0': Slave mode, integration timing is controlled off-chip through INT_TIME1, INT_TIME2 and INT_TIME3 pins
			[2]	0	'0': Pipelined mode '1': Triggered mode
			[3]	0	Enables('1')/disables('0') subsampling
			[4]	0	'1': Color subsampling scheme: 1:1:0:0:1:1:0:0 '0': B&W subsampling scheme: 1:0:1:0:1
			[5]	0	Enable dual slope
			[6]	0	Enable triple slope
			[7]	0	Enables continued row select (that is, assert row select during pixel read out)
	seqmode2	57	[4:0]	'10000'	Must be overwritten with '10001' to this register after startup, before readout.
			[6:5]	'00'	Number of active windows: "00": 1 window "01": 2 windows "10": 3 windows "11": 4 windows
	seqmode3	58	[0]	'1'	Enables the generation of the CRC10 on the data and sync channels
			[1]	'0'	Not applicable
			[2]	'0'	Enable column fpn calibration
			[5:3]	"001"	Number of frames in nondestructive read out: "000": invalid "001": one reset, one sample (default mode) "010": one reset, two samples ...
			[6]	0	Controls the granularity of the timer settings (only for those that have 'granularity selectable' in the description): '0': Expressed in number of lines '1': Expressed in clock cycles (multiplied by 2**seqmode4[3:0])
			[7]	0	Allows delaying the syncing of events that happen outside of ROT to the next ROT. This avoids image artefacts.

Table 14. Internal Registers (continued)

Block	Register Name	Address [6..0]	Field	Reset Value	Description
	seqmode4	59	[3:0]	0x00	Multiplier factor ($=2^{seqmode4[3:0]}$) for the timers when working in clock cycle mode
			[5:4]	0x0	Selects the source signals to put on the digital test pins (monitor pins): "00": integration time settings "01": EOS signals "10": frame sync signals "11": functional test mode
			[6]	'0'	Reverse read out in X direction
			[7]	'0'	Reverse read out in Y direction
	window1_1	60	[7:0]	0x00	Y start address for window 1
	window1_2	61	[1:0]	0x00	Y start address for window 1
			[7:2]	0x00	X start address for window 1

	Fix34	104	[0]	0	Reserved, fixed value, write 0x4 to it

Detailed Description of Internal Registers

The registers must be changed only during idle mode, that is, when seqmode1[0] is '0'. Uploaded registers have an immediate effect on how the frame is read out. Parameters uploaded during readout may have an undesired effect on the data coming out of the images.

MBS Block

The register block contains registers for sensor testing and debugging. All registers in this block must remain unchanged after startup.

LVDS Clock Divider Block

This block controls division of the input clock for the LVDS transmitters or receivers. This block also enables shutting down one or all LVDS channels. For normal operation, this register block must remain untouched after startup.

AFE Block

This register block contains registers to shut down ADC channels or the complete AFE block. This block also contains the register for setting the PGA gain: AFE_mode[5:3]. Refer to [Electrical Specifications](#) on page 5 for more details on the PGA settings.

Biasing Block

This block contains several registers for setting biasing currents for the sensor. Default values after startup must remain unchanged for normal operation of the sensor.

Image Core Block

The registers in this block have an impact on the pixel array itself. Default settings after startup must remain unchanged for normal operation of the image sensor.

Data Block

The data block is positioned in between the analog front end (output stage + ADCs) and the LVDS interface. It muxes the outputs of 2 ADCs to one LVDS block and performs some minor data handling:

■ CRC calculation and insertion

■ Training and test pattern generation

The most important registers in this block are:

Dataconfig. The dataconfig1[7:6] and dataconfig2[7:0] registers insert a training pattern in the LVDS channels to sync the LVDS receivers.

Datachannels. DatachannelX_1 and DatachannelX_2 (with X=0 to 12) are registers that allow you to enable or disable the FPN correction (DatachannelX_1[1]), and generate a test pattern if necessary (datachannelX_1[5:4] and datachannelX_2[7:0]).

Sequencer Block

The sequencer block group registers allow enabling or disabling image sensor features that are driven by the onboard sequencer. This block consists of the following registers:

Seqmode1. The seqmode1 registers have the following subregisters:

Seqmode1[0]: Enables image capture, must be '1' during image acquisition.

Seqmode1[1]: This subregister has two modes:

'1': In this default mode the integration timing is generated on-chip.

'0': In this slave mode, the integration timing must be generated through the int_time1, int_time2, and int_time3 pins.

Seqmode1[2]: This bit enables pipelined (0) or triggered (1) mode.

Seqmode1[3]: Enable (1) or disable (0) subsampling.

Seqmode1[4]: This bit sets the type of subsampling scheme used when subsampling is enabled.

'1': Color (1:1:0:0:1:1:0:0:1...)

'0': Black and White (1:0:1:0:1)

Seqmode1[5]: This bit enables or disables the dual slope integration.

Seqmode1[6]: This bit enables or disables the triple slope integration.

Seqmode2. The seqmode2 register consists of only two subregisters:

Seqmode2[4:0]: Default value after startup is '10000', but this must be overwritten with the new value '10001' immediately after startup.

Seqmode2[6:5]: These two bits set the number of active windows:

'00': 1 window

'01': 2 windows

'10': 3 windows

'11': 4 windows (max)

Seqmode3. The seqmode3 register consists of the following subregisters:

Seqmode3[0]: This bit enables or disables the CRC10 generation on the data and sync channels

Seqmode3[1]: Enables or disables black level calibration

Seqmode3[2]: Enables or disables column FPN correction

Seqmode3[5:3]: Enables or disables, and sets the number of frames grabbed in nondestructive readout mode.

'000': Invalid

'001': Default, 1 reset, 1 sample

'010': 1reset, 2 samples

'011': 1 reset, 3 samples

Seqmode3[6]: Controls the granularity of the timer settings (only for those that have 'granularity selectable' in the description). As a result, all timer settings are set either in number of applied clock cycles, or in the number of 'readout lines'.

'0': expressed in number of lines

'1': expressed in clock cycles (multiplied by 2**seqmode4 [3:0])

Seqmode3[7]: Allows syncing of events that happen outside of ROT to be delayed to the next ROT to avoid image artifacts.

Seqmode4. This register consists of four subregisters:

Seqmode4[3:0]: Multiplier factor (2**seqmode4[3:0]) for the timers when working in clock cycle mode.

Seqmode4[5:4]: Selects the source signals to be put on the digital test pins (monitor1, monitor2, and monitor3 pins)

"00": integration time settings

"01": EOS signals

"10": frame sync signals

"11": functional test mode

Seqmode4[6]: Enables (1) and disables (0) reverse X read out.

Seqmode4[7]: Enables (1) and disables (0) reverse Y read out.

Y1_start (60 and 61, 10 bit). These registers set the Y start address for window 1 (default window).

X1_start (61, 6bit). This register sets the X start address for window 1 (default window).

Y1_end (62 and 63, 10 bit). These registers set the Y end address for window 1 (default window).

X1_kernels (63, 6 bit). This register sets the number of kernels or X width to be read out for window 1 (default window).

Y2_start (64 and 65, 10 bit). These registers set the Y start address for window 2 (if enabled).

X2_start (65, 6bit). This register sets the X start address for window 2 (if enabled).

Y2_end (66 and 67, 10 bit). These registers set the Y end address for window 2 (if enabled).

X2_kernels (67, 6 bit). This register sets the number of kernels or X width to be read out for window 2 (if enabled).

Y3_start (68 and 69, 10 bit). These registers set the Y start address for window 3 (if enabled).

X3_start (69, 6bit). This register sets the X start address for window 3 (if enabled).

Y3_end (70 and 71, 10 bit). These registers set the Y end address for window 3 (if enabled).

X3_kernels (71, 6 bit). This register sets the number of kernels or X width to be read out for window 3 (if enabled).

Y4_start (72 and 73, 10 bit). These registers set the Y start address for window 4 (if enabled).

X4_start (73, 6bit). This register sets the X start address for window 4 (if enabled).

Y4_end (74 and 75, 10 bit). These registers set the Y end address for window 4 (if enabled).

X4_kernels (75, 6 bit). This register sets the number of kernels or X width to be read out for window 4 (if enabled).

Res_length (76 and 77). This register sets the length of the internal pixel array reset (how long are all pixel reset simultaneously). This value is expressed in 'number of lines' or in clock cycles (depends on seqmode3[6]).

Res_dsts_length. This register sets the length of the internal dual and triple slope reset pulses when enabled. This value is expressed in 'number of lines' or in clock cycles (depends on seqmode3[6]).

Tint_timer (79 and 80). This register sets the length of the integration time. This value is expressed in 'number of lines' or in clock cycles (depends on seqmode3[6]).

Tint_ds_timer (81 and 82). This register sets the length of the dual slope integration time. This value is expressed in 'number of lines' or in clock cycles (depends on seqmode3[6]).

Tint_ts_timer (83 and 84). This register sets the length of the triple slope integration time. This value is expressed in 'number of lines' or in clock cycles (depends on seqmode3[6]).

Data Interface (SPI)

The serial 4-wire interface (or Serial to Parallel Interface) uses a serial input or output to shift the data in or out the register buffer. The chip's configuration registers are accessed from the outside world through the SPI protocol. A 4-wire bus runs over the chip and connects the SPI I/Os with the internal register blocks.

The interface consists of:

- cs_n: chip select, when LOW the chip is selected
- clk: the spi clock
- in: Master out, Slave in, the serial input of the register
- out: Master in, Slave out, the serial output of the register

SPI Protocol

The information on the data 'in' line is:

- A command bit C, indicating a write ('1') or a read ('0') access
- 7-bit address
- 8-bit data word (in case of a write access)

The data 'out' line is generally in High Z mode, except when a read request is performed.

Data is always written on the bus on the falling edge of the clock, and sampled on the rising edge, as seen in [Figure 9](#) and [Figure 10](#). This is valid for both the 'in' and 'out' bus. The system clock must be active to keep the SPI uploads stored on the chip. The SPI clock speed must be slower by a factor of 30 when compared to the system clock (315 MHz nominal speed).

Figure 9. Write Access (C='1')

The out line is held to High Z. The data for the address A is transferred from the shift register to the active register bank (that is, sampled) on a rising edge of cs_n. Only the register block with address A can write its data on the 'out' bus. The data on 'in' is ignored.

Figure 10. Read Access (C='0')

Image Sensor Timing and Readout

The timing of the sensor consists of two parts. The first part is related to the exposure time and the control of the pixel. The second part is related to the read out of the image sensor. Integration and readout are in parallel or triggered. In the first case, the integration time of frame I is ongoing during the readout of frame I-1. **Figure 11** shows this parallel timing structure.

The readout of every frame starts with a FOT, during which the analog value on the pixel diode is transferred to the pixel memory element. After this FOT, the sensor is read out line by line. The read out of every line starts with a ROT, during which the pixel value is put on the column lines. Then the pixels are selected in

groups of 24 (12 on rising edge, and 12 on the falling edge of the internal clock). So in total, 54 kernels of 24 pixels are read out every line. The internal timing is generated by the sequencer. The sequencer can operate in two modes: master mode and slave mode. In master mode, all internal timing is controlled by the sequencer, based on the SPI settings. In slave mode, the integration timing is directly controlled by over three pins, and the readout timing is still controlled by the sequencer. The seqmode1[1] register of the SPI selects between the master and slave modes.

Figure 11. Global Readout Timing (Parallel)

Pipelined Shutter

Integration and readout occur in parallel and are continuous. You only need to start and stop the batch of image captures.

Integration of frame N is always ongoing during readout of frame N-1. The readout of every frame starts with a FOT, during which the analog value on the pixel diode is transferred to the pixel memory element. After this FOT, the sensor is read out line by line. The readout of every line starts with a ROT, during which the pixel value is put on the column lines. Then the pixels are muxed in the correct ADCs, processed, and then sent to the LVDS output block.

Figure 12. Integration and Readout for Pipelined Shutter

You have two options in the pipelined shutter mode. The first option is to program the reset and integration through the configuration interface and let the sequencer handle integration time automatically. This mode is called master mode. The second option is to drive the integration time through an external pin. This mode is called slave mode.

Programming the Exposure Time

In master mode, the exposure time is configured in two distinct methods (controlled by register seqmode3[6]):

- #lines: Obvious, changing signals that control integration time. They are always changed during ROT to avoid any image artefacts.
- #clock cycles: Must be multiplied by $(2^{seqmode4[3:0]})$. When the counter expires, changes are put into effect immediately. Asserting the configuration signal (seqmode3[7]) forces delaying signal updates until the next ROT.

Table 15 lists the user programmable timer settings and how they are interpreted by the hardware.

Table 15. User Programmable Timer Settings

Setting	Granularity
reg_res_length	Lines/cycles
reg_tint_timer	Lines/cycles
reg_tint_ds_timer	Lines/cycles
reg_tint_ts_timer	Lines/cycles
reg_rot_timer	clock cycles
reg_fot_timer	clock cycles
reg_sel_pre_timer	clock cycles
reg_precharge_timer	clock cycles
reg_sample_timer	clock cycles
reg_vmem_timer	clock cycles
reg_delayed_rdt_timer	Lines/cycles

Note that the seqmode3[7] can also be used to sync the user signals in slave mode. The behavior is exactly the same.

Master Mode

In master mode the reset and exposure time is written in registers.

Figure 13. Integration and Image Readout in Master Mode

Ensure that the added value of the registers res_length and tint_timer always exceeds the number of lines that are read out. This is because the sequencer samples a new image after integration is complete, without checking if image readout is finished. Enlarging res_length to accommodate for this has no impact on image capture.

Slave Mode

In slave mode, the register values of `res_length` and `tint_timer` are ignored. The integration time is controlled by the `int_time` pin. The relationship between the input pin and the integration time is shown in Figure 14. When the input pin `int_time` is asserted, the pixel array goes out of reset and exposure can begin. When `int_time` goes low again and the desired exposure time is reached, the image is sampled and read out can begin.

Figure 14. Integration and Image Readout in Slave Mode

Changing a pixel's reset level during line readout might result in image artefacts during a small transient period. As a result, it is advised to only change the value of `int_time` during ROT.

Triggered Shutter

The two main differences in the pipelined shutter mode are:

- One single image is read upon every user action.
- Integration (and read out) is under control of the user through pin `int_time`.

This means that for every frame, you need to manually intervene. The pixel array is kept in reset state until you assert the `int_time` input. Similar to the pipelined shutter mode, there is a master mode in which the sequencer can control the integration time, or a slave mode in which you can define the integration time.

Figure 15. Integration and Readout for Triggered Shutter

www.DataSheet4U.com

The possible applications for this triggered shutter mode are:

- Synchronize external flash with exposure
- Apply extremely long integration times (only in slave mode)

Master Mode

In this mode, a rising edge on `int_time1` pin is used to trigger the start of integration and read out. The `tint_timer` defines the integration time independent of the assertion of the input pin `int_time1`. After the integration time counter runs out, the FOT automatically starts and the image readout is done. During readout, the image array is kept in reset. A request for a new frame is started again when a new rising edge on `int_time` is detected. The time of the falling edge is not important in this mode.

Slave Mode

Integration time control is identical to the pipelined shutter slave mode. The `int_time1` pin controls the start of integration. When `int_time` is deasserted, the FOT starts (analog value on the pixel diode is transferred to the pixel memory element). Only at that time, image read out can start (similar to the pipelined read out). During read out, the image array is kept in reset. A request for a new frame is started when `int_time` goes high again.

Windowing

A fully configurable window can be selected for readout.

Figure 16. Window Selected for Readout

The parameters to configure this window are:

x_start. The sensor reads out 24 pixels in one single clock cycle. The granularity of configuring the X start position is also 24. Every value written to the `windowX_2` register must be multiplied by 24 to find the corresponding column in the pixel array.

x_kernels. The number of columns that is read out ($x_kernels \times 24$ in full frame mode) in subsampling mode $x_kernels \times 48$ represents the number of columns over which subsampling is done. The `x_kernels` value must be written to the `windowX_4` register.

y_start. The starting line of the readout window, granularity of 1. Note that in subsample mode, the correct `y_start` position must be uploaded (exact value depends on color or B/W subsampling mode). This value must be written to the `windowX_1` and `windowX_2` register.

y_end. The end line of the readout window, granularity of 1. In all cases (even in reverse scan), `y_end` are larger than `y_start`. Note that in subsample mode, the correct `y_end` position must be uploaded (exact value depends on color or B/W subsampling mode). This value must be written to the `windowX_3` and `windowX_4` register.

In case of windowing, the effective readout time is smaller than in full frame mode, because only the relevant part of the image array is accessed. As a result, it is possible to achieve higher frame rates.

Reverse Scan

Reverse scanning is supported in the X and Y direction. Line 0 (first line on the output) is the top line in normal mode and the bottom line in reverse scanning, as shown in Figure 17. As a result, the line numbers always increment. When reverse scanning in X, the operation is analogous. To enable reverse readout in X and Y, set the seqmode4[6:7] bits. In addition, the Y_start and X_start addresses must be changed to the new starting address.

Figure 17. Normal and Reverse Scanning in Y

Multiple Windows

The sequencer supports the readout of four different windows, randomly positioned over the pixel array. The images are read out sequentially. That is, window 1 is read out before window 2, even if both windows show some overlap. Next, windows 3 and 4 are read out. You can configure the number of windows used in the application (one to four). Figure 18 shows how to configure two windows spread over the image array.

Figure 18. Multiple Windows Read from the Same Pixel Array

Figure 19 shows the sequence of integration and read out for multiple windows. The handling of integration time is identical to the single window mode (except that in this case, the maximum integration time is equal to the sum of the y_widths of the two windows). Read out starts with a FOT that is similar to single window mode. After the FOT, all lines of window 1 are read, followed by the lines of window 2.

Figure 19. Exposure and Read Out of Multiple Windows

If the X size of the windows are not identical, the integration time in function of the number of lines read presents multiple slopes (proportional to the X size of these windows). Because this can cause confusion when programming the integration time, it is easier to configure all timer registers using the clock cycle configuration instead of the 'line' configuration.

Multiple Slopes

Dynamic range can be extended by the multiple slope capabilities of the sensor. The four colored lines in Figure 20 represent analog signals of the photodiode of four pixels, which decrease as a result of exposure. The slope is determined by the amount of light at each pixel (the more light, the steeper the slope). When the pixels reach the saturation level, the analog does not change despite further exposure. Without the multiple

slope capabilities, the pixels p3 and p4 are saturated before the end of the exposure time, and no signal is received. However, when using multiple slopes, the analog signal is reset to a second or third reset level (lower than the original) before the integration time ends. The analog signal starts decreasing with the same slope as before, and pixels that were saturated before could be nonsaturated at read out time. For pixels that never reach any of the reset levels (for example, p1 and p2) there is no difference between single and multiple slope operation.

By choosing the time stamps of the double and triple slope resets (typical at 90% and 99% of the integration, configurable by the user), it is possible to have a nonsaturated pixel value even for pixels that receive a huge amount of light.

Figure 20. Dynamic Range Extended by Multiple Slope Capability

The reset levels are configured through external (power) pins. In master mode, the time stamps of the double and triple slope resets are configured in a method similar to configuring the exposure time. The time stamps are enabled through the registers seqmode1[5] and seqmode1[6], and their values are expressed in line or clock cycles in the registers reg_tint_ds_timer and reg_tint_ts_timer.

Figure 21. Triple Slope Timing in Master Mode

In slave mode, the values of res_length, tint_timer, tint_DS_timer, and tint_TS_timer in the configuration registers are ignored. You have full control through the pins int_time, int_time_ds, and int_time_ts. You must configure the multiple slope parameters for the application and interpret the pixel data accordingly.

Figure 22. Triple Slope Timing in Slave Mode

Column FPN Correction

The column FPN of the sensor is improved by the offset correction of the columns. At the start of every frame, before read out of the actual lines is done, a fixed voltage is applied at the columns and these values are read out like a real data line. Inside the data block, the 'pixel' data for that line is stored in an on-chip FPN memory. When the correction is enabled, the corresponding FPN value is subtracted from the incoming pixel data.

This FPN correction must be enabled for every output separately. The registers used to configure the correction are:

- **datachannelX_1 with X from 0 to 11.** The field [1] of these registers enables the offset corrections of the specific output channel.

Note Do not change the settings of datachannel12_1. This channel contains synchronization data, not pixel data. If fpn correction is enabled on this channel, the synchronization data becomes corrupt.

- **seqmode3.** The field[2] must be '1'. It enables the generation of the line of reference voltages at the columns.

Figure 23 and Figure 24 show the effect of enabling the column FPN correction. These images are magnified up to five times.

Figure 23. Dark Image Without FPN Correction (5x Amplified)

Figure 24. Dark Image With FPN Correction Enabled (5x Amplified)

Image Format and Read Out Protocol

The active area read out by the sequencer in full frame mode is shown in [Figure 25](#). Before the actual pixels are read out, one dummy line is read to enable column FPN calibration. A reference voltage is applied to the columns and the entire line is read as if real pixel values are placed on the columns.

Pixels are always read in multiples of 24 (one value to every channel in the AFE). The last time slot contains not only valid pixels, but also two dummy columns, six grey columns, and eight black columns.

Figure 25. Sensor Read Out Format

The following sections discuss the appearance of the output (data and synchronization codes) in several relevant configurations. Twelve output channels are connected to the 24 ADCs and handle the data. One additional channel contains all the synchronization codes for the receiver. This indicates, for example, the start of a frame, the end of a frame, whether the data channels contain data, CRC, a training pattern, and so on. The sequencer provides the synchronization channel with the correct synchronization or protocol signals, as shown in Figure 26. The synchronization codes are listed in Table 16. Note that a FS also serves as LS, and vice versa.

Figure 26. Data and Sync Channel Overview

Table 16. Synchronization Codes

Sync code	Abbreviation	10-Bit Code
Frame Start	FS	0x059
Line Start	LS	0x056
Frame End	FE	0x05A
Line End	LE	0x055
Grey/Black Cols	GBC	0x0A9
CRC	CRC	0x0A6
FPN stored values	FPN	0x13C
Normal Data	D	0x193
Training Pattern	T	T

Full Frame Mode

In this operation mode, the entire sensor shown in Figure 25 on page 26 is read out. Figure 27 shows the internal state of the sequencer, and the behavior of the data and sync channels (overview and detail of one line).

Figure 27. Full Frame Mode Read Out

This table provides a detailed overview of remapping one full row read out.

Table 17. Remapping Scheme for One Row

timeslot	ch0	ch1	ch2	ch3	ch4	ch5	ch6	ch7	ch8	ch9	ch10	ch11

CRC												

In this operation mode, only part of the sensor is read out, as shown by the shaded area in [Figure 28](#). A clear distinction is made with the single window mode that does not contain the timeslot 54, because the output synchronization protocol is slightly different.

Figure 29. Waveform for Single Window Containing Timeslot 54

Single Window Mode Not Containing Timeslot 54

In this operation mode, only part of the sensor is read out, as shown in [Figure 30](#). Although the window is defined as not containing any data from timeslot 54, it is read out to provide information on grey and black columns to the user. This results in some minor differences between the waveforms from [Figure 29](#) on page 30 and [Figure 31](#).

Figure 30. Single Window Not Containing Timeslot 54

[Figure 31](#) shows the internal state of the sequencer, and the behavior of the data and sync channels (overview and detail of one line) for this window mode.

Figure 31. Waveform for Single Window NOT Containing Timeslot 54

www.DataSheet4U.com

Note that the dummy black line is read completely.

Reading out multiple windows does not differ from combining the windowed modes in sections [Single Window Mode Containing Timeslot 54](#) on page 30 and [Single Window Mode Not Containing Timeslot 54](#). The dummy black line again spans the entire width of the sensor and is processed only once, before all configured windows are read. The dummy black line is independent of the window sizes.

Package Information

Figure 32. Package Outline Drawing with Glass

The total distance from the bottom of the μ PGA package (same as the PCB plane) to the top of the die surface is 19.016 mm.

Figure 33. Pixel Active Area Dimensions

Package with Glass Cross Section

Figure 34. Package Cross Section

www.DataSheet4U.com

Glass Lid

The LUPA 1300-2 monochrome and color image sensor uses a glass lid without any coatings. Figure 36 shows the transmission characteristics of the glass lid.

As seen in Figure 36, no infrared attenuating color filter glass is used. You must provide this filter in the optical path when color devices are used.

Figure 36. Transmission Characteristics of the Glass lid

Handling Precautions

For proper handling and storage conditions, refer to the Cypress application note AN52561 at www.cypress.com.

Limited Warranty

Cypress Image Sensor Business Unit warrants that the image sensor products mentioned here, if properly used and serviced, conform to the seller's published specifications. They are free from defects in material and workmanship for one (1) year following the date of shipment.

Application Note References

- [AN54468](#): Interfacing the LUPA1300-2 with FPGA.

This application note describes the interface between the LUPA 1300-2 and the FPGA, as implemented in the LUPA 1300-2 demonstration kit CYIL2SM1300-EVAL. It also provides an overview of the architecture of the demonstration kit and the method used to synchronize channels.

Sales, Solutions, and Legal Information

Worldwide Sales and Design Support

Cypress offers standard and customized CMOS image sensors for consumer as well as industrial and professional applications. Consumer applications include solutions for fast growing high speed machine vision, motion monitoring, medical imaging, intelligent traffic systems, security, and barcode applications. Cypress's customized CMOS image sensors are characterized by very high pixel counts, large area, very high frame rates, large dynamic range, and high sensitivity.

Cypress maintains a worldwide network of offices, solution centers, manufacturer's representatives, and distributors. For more information on Image sensors, please contact imagesensors@cypress.com.
