μPD8259A PROGRAMMABLE INTERRUPT CONTROLLER

Description

The μ PD8259A is a programmable interrupt controller directly compatible with the 8080A/8085A/8086/8088 microprocessors. It can service eight levels of interrupts and contains on-chip logic to expand interrupt capabilities up to 64 levels with the addition of other μ PD8259A's. The user can choose a selection of priority algorithms to tailor the priority processing to meet his system requirements. These algorithms can be dynamically modified during operation, which expands the versatility of the system. The μ PD8259A is completely upward compatible with the μ PD8259-5, allowing software written for the μ PD8259-5 to run on the μ PD8259A/-2.

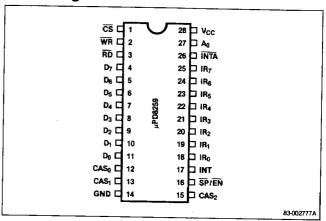

Features

	Eight-level priority controller
	Programmable base vector address
	Expandable to 64 levels
	Programmable interrupt modes (algorithms)
	Individual request mask capability
	Single +5 V power supply (no clocks)
	Full compatibility with 8080A /8085A /8086 /80

Ordering Information

Part Number	Package Type
μPD8259AC	28-pin plastic DIP
μPD8259AC-2	28-pin plastic DIP

Pin Configuration

Pin Identification

No.	Symbol	Function
1	CS	Chip select input
2	WR	Write input
3	RD	Read input
4-11	D ₇ -D ₀	Bidirectional data bus
12, 13, 15	CAS ₀ -CAS ₂	Cascade lines
14	GND	Ground
16	SP/EN	Slave program input / enable buffer output
17	INT	Interrupt output
18-25	IR ₀ -IR ₇	Interrupt request inputs
26	INTA	Interrupt acknowledge input
27	A ₀	Command select address input
28	V _{CC}	+5 V power supply

Pin Functions

Bidirectional Data Bus (D7-D0)

Three-state data bus used for interfacing to the system data bus. This bus carries control words, status information, and interrupt vector information.

Interrupt Request Inputs (IR₀-IR₇)

These are eight asynchronous inputs that operate in two modes. In the edge-triggered mode, the IR input must be raised from low to high and held high until it is acknowledged. In the level-triggered mode, the IR input requires only a high.

Cascade Lines (CAS₀-CAS₂)

These lines are used as a bus which controls multiple μ PD8259As in a master/slave configuration. When an μ PD8259A is a master, these lines are outputs. When a μ PD8259A is used as a slave, the lines are inputs.

Chip Select (CS)

When $\overline{\text{CS}}$ is low, the CPU can read and write to the $\mu\text{PD8259A}$. The INTA input operates independently of $\overline{\text{CS}}$.

Command Select Address Input (A₀)

The $\mu PD8259A$ uses this input with \overline{CS} and \overline{WR} to decode command words written by the CPU. A_0 is used with \overline{CS} and \overline{RD} to decode controller status information for the CPU to read. Typically, A_0 is connected to the A_0 address lines on the CPU.

Interrupt (INT)

When the μ PD8259A receives a valid interrupt request, the INT output goes high to interrupt the CPU. This pin should be connected directly to the interrupt pin on the CPU.

Interrupt Acknowledge (INTA)

This input line goes active low to indicate that the CPU has received an interrupt request from the μ PD8259A. INTA enables interrupt vector data onto the data bus.

Read Input (RD)

When both \overline{RD} and \overline{CS} are low, the $\mu PD8259A$ sends its status information to the data bus so the CPU can read it

Write Input (WR)

The μPD8259A can receive command words from the CPU when both WR and CS are low.

Slave Program Input/Enable Buffer Output (SP/EN)

This is a dual function pin. In the buffered mode, the enable buffer output is used to enable the buffer transceivers. In the non-buffered mode, when the \overline{SP} input is high, the μ PD8259A operates as a master and when the \overline{SP} input is low, the μ PD8259A operates as a slave.

Ground (GND)

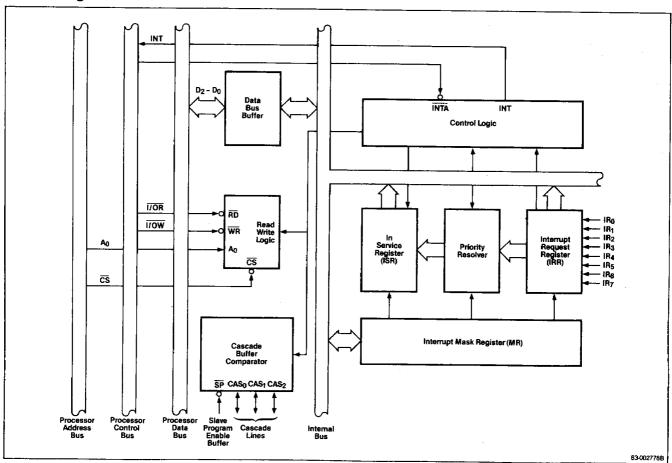

Ground

Power Supply (V_{CC})

Power supply input, +5 volts.

Block Diagram

Block Diagram Description

Interrupt Request Register (IRR) and In-Service Register (ISR)

The interrupt request and in-service registers store the incoming interrupt request signals appearing on the IR₀-IR₇ lines. The inputs requesting service are stored in the IRR while the interrupts actually being serviced are stored in the ISR. Refer to functional block diagram.

A positive transition on an IR input sets the corresponding bit in the interrupt request register. At the same time, the INT output of the $\mu\text{PD8259A}$ is set high. The IR input line must remain high until the first $\overline{\text{INTA}}$ input has been received. Multiple non-masked interrupts occurring simultaneously can be stored in the IRR. The incoming INTA sets the appropriate ISR bit, which is determined by the programmed interrupt algorithm, and resets the corresponding IRR bit. The ISR bit stays active high during the interrupt service subroutine until it is reset by the programmed end of interrupt command (EOI).

Priority Resolver

The priority resolver decides the priority of the interrupt levels in the IRR. When the highest priority interrupt is determined, it is loaded into the appropriate bit of the ISR by the first INTA pulse.

Data Bus Buffer

The three state 8-bit bidirectional data bus buffer interfaces the μ PD8259A to the systems data bus. It buffers the control word and status information being transferred between the μ PD8259A and the processor.

Read/Write Logic

The read/write logic accepts processor commands and stores them in its initialization command word (ICW) and operation command word (OCW) registers. This logic also controls the transfer of status information to the processor.

Chip Select (CS)

The μ PD8259A is enabled when this input receives an active low signal. When the \overline{CS} input is high, reading or writing of the μ PD8259A is inhibited.

Write (WR)

This active low signal instructs the $\mu PD8259A$ to receive command data from the processor.

Read (RD)

When the \overline{RD} input receives an active low signal, the status of the interrupt request register, in-service register, interrupt mask register or binary code of the interrupt level is placed on the data bus.

Interrupt (INT)

The interrupt output from the μ PD8259A is directly connected to the processor's INT input. The voltage levels of this output are compatible with the 8080A/8085A/8086/8088.

Interrupt Mask Register (IMR)

The interrupt mask register stores the bits which will mask the individual interrupt lines. The IMR masks the data in the ISR. Lower priority lines are not affected by masking a higher priority line.

Interrupt Acknowledge (INTA)

 $\overline{\text{INTA}}$ pulses cause the $\mu\text{PD8259A}$ to put vectoring information on the bus. The number of pulses depend upon whether the $\mu\text{PD8259A}$ is in the $\mu\text{PD8085A}$ mode or 8086/8088 mode.

Command Select Address Input (A₀)

 A_0 is usually connected to the processor's data bus. Together with \overline{RD} and $\overline{WR},$ it signals the loading of data into the command register or the reading of status data. Table 1 illustrates the basic operations performed. Note that it is divided into three functions: input, output, and bus disable distinguished by the $\overline{RD}, \overline{WR},$ and \overline{CS} inputs.

Table 1. µPD8259A Basic Operation

A ₀	D ₄	D ₃	RD	WR	<u>CS</u>	Operation
						Processor Input (Read)
0			0	1	0	IRR, ISR or IR → data bus (Note 1)
1			0	1	0	IMR → data bus
						Processor Output (Write)
0	0	0	1	0	0	Data bus → 0CW2
0	0	1	1	0	0	Data bus → OCW3
0	1	χ	1	0	0	Data bus → ICW1
1	X	Х	1	0	0	Data bus → OCW1, ICW2, ICW3, ICW4 (Note 2)
						Disable Function
X	Х	Х	1	1	0	Data bus → high impedance state
X	Χ	Χ	Χ	X	1	Data bus → high impedance state

Note:

- (1) The contents of OCW3 written prior to the read operation governs the selection of IRR, ISR or the interrupt level.
- (2) The sequencer logic on the μPD8259A aligns these commands in the proper order.

Cascade Buffer/Comparator

The IDs of all μ PD8259As are buffered and compared in the cascade buffer/comparator. See figure 4. The master μ PD8259A sends the ID of the interrupting slave device along the CAS₀, CAS₁ and CAS₂ lines to all slave devices. The cascade buffer/comparator compares its preprogrammed ID to the CAS₀, CAS₁ and CAS₂ lines. The next two INTA pulses strobe the preprogrammed, 2 byte call routine address onto the data bus from the slave whose ID matches the code on the CAS₀, CAS₁ and CAS₂ lines.

Slave Program (SP)

The interrupt capability can be expanded to 64 levels by cascading multiple $\mu PD8259As$ in a master plus slaves array. See figure 4. The master controls the slaves through the CAS₀, CAS₁ and CAS₂ lines. The \overline{SP} input to the device selects the CAS₀, CAS₁ and CAS₂ lines as either outputs ($\overline{SP}=1$) for the master or as inputs ($\overline{SP}=0$) for the slaves. If only one $\mu PD8259A$ is used, the SP input must be set to a logic 1, since it is functioning as a master.

Absolute Maximum Ratings

 $T_A = 25$ °C

Power supply voltage, V _{CC}	-0.5 to +7.0 V(Note 1)
Input voltage, V _I	$-1.0 \text{ V to V}_{CC} + 1.0 \text{ V}$
Output voltage, V ₀	-0.5 V to V _{CC} + 0.5 V
Operating temperature, T _{OPT}	0 to +70°C
Storage temperature, T _{STG}	-65 to +150°C
Power dissipation, P _D	1.0 W

Note:

(1) With respect to ground.

Comment: Exposing the device to stresses above those listed in Absolute Maximum Ratings could cause permanent damage. The device is not meant to be operated under conditions outside the limits described in the operational sections of the specification. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Functional Description

The μ PD8259A functions are described in following paragraphs under these major headings:

- Interrupt Sequence
- 8080/8085A Mode
- 8086/8088 Mode
- · Initialization Command Words
- Operational Command Words
- Reading µPD8259A Status

Interrupt Sequence

The $\mu PD8259A$ derives its versatility from programmable interrupt modes and the ability to jump to any memory address through programmable CALL instructions.

The sequence used by the $\mu PD8259A$ to handle an interrupt depends upon whether an 8080A/8085A or 8080/8088 CPU is being used.

The following sequence demonstrates how the $\mu\text{PD8259A}$ interacts with the 8080A/8085A systems.

- (1) An interrupt(s) appearing on IR₀-IR₇ sets the corresponding IR bit(s) high. This in turn sets the corresponding IRR bit(s) high.
- (2) Once the IRR bit(s) has been set, the μPD8259A will resolve priorities according to the preprogrammed interrupt algorithm. It then issues an INT signal to the processor.
- (3) When the processor receives an INT, it issues an INTA to the μ PD8259A.
- (4) The NTA input to the μPD8259A from the processor group sets the highest priority ISR bit and resets the corresponding IRR bit. The NTA also signals the μPD8259A to place an 8-bit CALL instruction opcode (11001101) onto its data bus lines.
- (5) The CALL instruction code instructs the processor group to issue two more INTA pulses to the $\mu PD8259A$.

- (6) The two INTA pulses signal the μPD8259A to place its preprogrammed interrupt vector address onto the data bus. The first INTA releases the low order 8 bits of the address and the second INTA releases the high order 8 bits.
- (7) The μ PD8259As CALL instruction sequence is complete. A preprogrammed EOI command is issued to the μ PD8259A at the end of the interrupt service routine. This resets the ISR bit and allows the μ PD8259A to service the next interrupt.

The following sequence demonstrates how the µPD8259A interacts with the 8086/8088 systems.

- (1), (2), (3) Same as for 8080A/8085A.
- (4) During the first INTA from the processor, the μPD8259A does not drive the data bus. The highest priority ISR bit is set and the corresponding IRR bit is reset.
- (5) The μ PD8259A puts vector information onto the data bus on the second INTA pulse from the 8086/8088.
- (6) There is no third INTA pulse in this mode. In the AEOI mode the ISR bit is reset at the end of the second INTA pulse, or it remains set until an EOI command is issued.

8080/8085A Mode

For these processors, the μ PD8259A is controlled by three INTA pulses. The first INTA pulse will cause the μ PD8259A to put the CALL opcode onto the data bus. See table 2. The second and third INTA pulses will cause the upper and lower address of the interrupt vector to be released on the bus. See tables 3 and 4.

8086/8088 Mode

In this mode only two $\overline{\text{INTA}}$ pulses are sent to the $\mu\text{PD8259A}$. After the first $\overline{\text{INTA}}$ pulse, the $\mu\text{PD8259A}$ does not output a CALL but internally sets priority resolution. If it is a master, it sets the cascade lines. The interrupt vector is output to the data bus on the second $\overline{\text{INTA}}$ pulse. See table 5.

Initialization Command Words

ICW1 and ICW2

LTIM If LTIM = 1, then the μ PD8259A operates in the level interrupt mode. Edge detect logic on the interrupt inputs is disabled.

ADI CALL address interval. If ADI = 1 then the interval is four; if ADI = 0 then the interval is eight.

SNGL (Single) Indicates that there is only one μ PD8259A in the system. If SNGL=1, no ICW3 is issued.

IC4 If this bit is set, ICW4 has to be read. If ICW4 is not needed, set IC4 to logic 0.

A5-A₁₅ Defines the page starting address of the service routines. In an 8085A system, the eight request levels generate CALLs to eight locations equally spaced in memory. These can be programmed to be spaced at intervals of four or eight memory locations, allowing eight routines to occupy a page of 32 or 64 bytes, respectively.

The address form is two bytes long (A_0 - A_{15}). When the routine interval is four, A_0 - A_4 are automatically inserted by the μ PD8259A, while A_5 - A_{15} are programmed externally. When the routine interval is eight, A_0 - A_5 are automatically inserted by the μ PD8259A, while A_6 - A_{15} are programmed externally.

The eight-byte interval maintains compatibility with current software, while the four-byte interval is best for a compact jump table.

In an 8086/8088 system, $T_7\text{--}T_3$ are inserted in the five most significant bits of the vectoring byte. The $\mu\text{PD8259A}$ sets the three least significant bits according to the interrupt level.

ICW3

This word is read only when there is more than one $\mu PD8259A$ in the system and cascading will be used. SNGL of ICW1 is programmed for logic 0. ICW3 will load the 8-bit slave register. The functions of this register are, in the master mode, when $\overline{SP}=1$ or BUF = 1 and M/S = 1 in ICW4, a 1 is set for each slave in the system. The master then releases byte 1 of the call sequence (for 8080A/8085A system) and enables the corresponding slave via the cascade lines to release vector bytes 2 and 3 (byte 2 only for 8086/8088).

In the slave mode, when $\overline{SP}=0$ or BUF = 1 and M/S = 0 in ICW4, bits ID₂-ID₀ identify the slave. The slave compares its cascade input with these bits and if they are equal, vector bytes 2 and 3 of the call sequence (byte 2 only for 8086/8088) are released by the slave on the data bus.

ICW4

M/S

SNFM If SNFM = 1, the special fully nested mode is programmed.

BUF If BUF = 1, the buffered mode is programmed. In the buffered mode, SP/EN becomes an enable output and the master/slave determination is by M/S.

If the buffered mode is selected, M/S=1 means the μ PD8259A is programmed to be a master, M/S=0 means the μ PD8259A is

programmed to be a slave. If BUF = 0, M/S

has no function.

AEOI If AEOI = 1, the automatic end of interrupt

mode is programmed.

 μ PM Microprocessor mode: μ PM = 0 sets the

 μ PD8259A for 8085A system operation; μ PM = 1 sets the μ PD8259A for 8086 system

operation.

Figure 1 illustrates the command word initialization sequence.

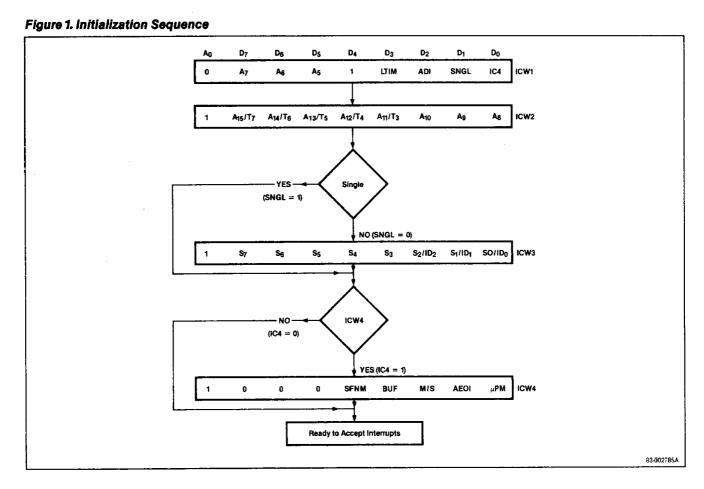

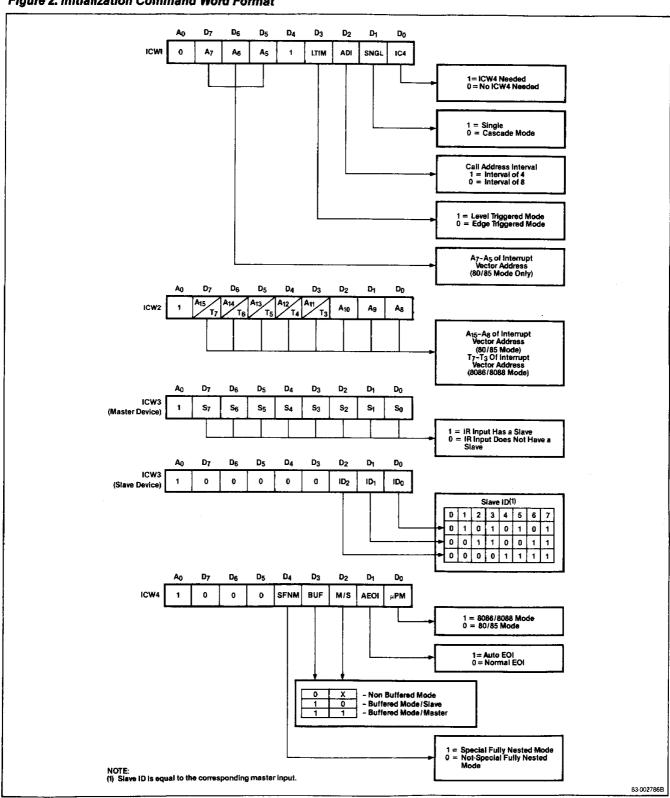

Figure 2 illustrates the initialization command word format.

Figure 2. Initialization Command Word Format

Operational Command Words

Once the μ PD8259A has been programmed with initialization command words, it can be programmed for the appropriate interrupt algorithm by the operation command words (OCW). See figure 3. Interrupt algorithms in the μ PD8259A can be changed at any time during program operation by issuing another set of operation command words. The following sections describe the various algorithms available and their associated OCWs.

Interrupt Masks

The individual interrupt request input lines are maskable by setting the corresponding bits in the interrupt mask register to a logic 1 through OCW1. The actual masking is performed upon the contents of the inservice register. For example, if interrupt request line 3 is to be masked, then only bit 3 of the IMR is set to logic 1. The IMR in turn acts upon the contents of the ISR to mask bit 3.

Once the μ PD8259A has acknowledged an interrrupt, the masked interrupt input inhibits lower priority requests from being acknowledged. There are two means of enabling these lower priority interrupt lines. The first is by issuing an end of interrupt (EOI) through operation command word 2 (OCW2), thereby resetting the appropriate ISR bit. The second approach is to select the special mask mode through OCW3. The special mask mode (SMM) and end of interrupt (EOI) are described later.

Fully Nested Mode

The fully nested mode is the μ PD8259A's basic operating mode. It will operate in this mode after the initialization sequence without requiring operation command words for formatting. The order of priority is determined by IR0–IR7. IR0 has the highest priority. After the interrupt has been acknowledged by the processor and system controller, only higher priorities will be serviced. Upon receiving an $\overline{\text{INTA}}$, the priority resolver determines the priority of the interrupt, sets the corresponding IR bit, and outputs the vector address to the data bus. The EOI command resets the corresponding ISR bits at the end of its service routines.

Rotating Priority Mode Commands

The two variations of rotating priorities are the auto rotate and specific rotate modes. These two modes are typically used to service interrupting devices of equivalent priorities.

Auto Rotate Mode. Programming the auto rotate mode through OCW2 assigns priorities 0–7 to the interrupt request inputs. Interrupt line IR₀ is set to the highest priority and IR₇ to the lowest. Once an interrupt has been

serviced, it is automatically assigned the lowest priority. That same input must then wait for the devices ahead of it to be serviced before it can be acknowledged again. The auto rotate mode is selected by programming OCW2 in the following way: set rotate priority bit R to a logic 1, program EOI to a logic 1 and SECOI to a logic 0. The EOI and SEOI commands are discussed later. The following is an example of the auto rotate mode with devices requesting interrupts on line IR2 and IR5.

(1) Before interrupts are serviced:

In-service register

IS ₇	IS ₆	IS ₅	IS ₄	IS ₃	IS ₂	IS ₁	IS _O
0	0	1	0	0	1	0	0

Priority status register highest priority IR7 IR6 IR5 IR4 IR3 IR2 IR1 IR0

According to the priority status register, IR_2 has a higher priority than IR_5 and will be serviced first.

(2) After interrupts are serviced:

In-service register

IS ₇	IS ₆	IS ₅	IS ₄	IS ₃	IS ₂	IS ₁	IS ₀
0	0	1	0	0	0	0	0

Priority	status	registe		highest prior					
IR ₂	IR ₁	IR _O	IR ₇	IR ₆	IR ₅	IR ₄	IR ₃		

At the completion of IR₂'s service routine, the corresponding in-service register bit (IS₂) is reset to logic 0 by the preprogrammed EOI command. IR₂ is then assigned the lowest priority level in the priority status register. The μ PD8259A is now ready to service the next highest interrupt, which, in this case, happens to be IR₅.

Specific Rotate Mode. The priorities are set by programming the lowest level via OCW2. Then, the μ PD8259A automatically assigns the highest priority. If, for example, IR₃ is set to the lowest priority (bits L₂, L₁, L₀ form the binary code of the bottom priority level), then IR₄ will be set to the highest priority. The specific rotate mode is selected by programming OCW2 in the following manner: set rotate priority bit R to a logic 1, program EOI to a logic 0, SEOI to a logic 1 and L₂, L₁, L₀ to the lowest priority level. If EOI is set to a logic 1, the ISR bit defined by L₂, L₁, L₀ is reset.

8-102

End of Interrupt (EOI) and Specific End of Interrupt (SEOI)

The end of interrupt (EOI) or specific end of interrupt (SEOI) command must be issued to reset the appropriate in-service register bit before the completion of a service routine. Once the ISR bit has been reset to logic 0, the μ PD8259A is ready to service the next interrupt.

Two types of EOI's are available to clear the appropriate ISR bit depending on the μ PD8259A's operating mode.

Non-Specific End of Interrupt (EOI). When operating in interrupt modes where the priority order of the interrupt inputs is preserved, such as the fully nested mode, the particular ISR bit to be reset at the completion of the service routine can be determined. A non-specific EOI command automatically resets the highest priority ISR bit of those set. The highest priority ISR bit must necessarily be the interrupt being serviced and must necessarily be the service subroutine returned from.

Specific End of Interrupt (SEOI). When operating in interrupt modes where the priority order of the interrupt inputs is not preserved, such as the rotating priority mode, the last serviced interrupt level may not be known. In these modes, a specific end of interrupt must be issued to clear the ISR bit at the completion of the interrupt service routine. The SEOI is programmed by setting the appropriate bits in OCW2 to logic 1's. See figure 3. Both the EOI and SEOI bits of OCW2 must be set to a logic 1 with L_2 , L_1 , L_0 forming the binary code of the ISR bit to be reset.

Special Mask Mode

Setting up an interrupt mask through the interrupt mask register by setting the appropriate bits in OCW1 to a logic 1 inhibits lower priority interrupts being acknowledged. In applications requiring that the lower priorities be enabled while the IMR is set, the special mask mode can be used. The SMM is programmed in OCW3 by setting the appropriate bits to a logic 1. Once the SMM is set, the μ PD8259A remains in this mode until it is reset. The special mask mode does not affect the higher priority interrupts.

Poll Mode

In poll mode, the processor must be instructed to disable its interrupt input (INT). Interrupt service is initiated through software by a poll command. Poll mode is programmed by setting the poll mode bit in OCW3 to logic 1 during a WR Pulse. The following RD pulse is then considered as an interrupt acknowledge. If an interrupt input is present, the $\overline{\text{RD}}$ pulse sets the appropriate ISR bit and reads the interrupt priority level. Poll mode is a one time operation and must be programmed through OCW3 before every read. The

word format which is strobed onto the data bus during the poll mode follows:

D ₇	D ₆	05	D ₄	D_3	D ₂	D ₁	Do
1	Х	X	х	х	W ₂	W ₁	W ₀

where:

- I = 1 if there is an interrupt requesting service
- I = 0 if there are no interrupts
- $\mbox{W}_2\mbox{-}\mbox{W}_0$ forms the binary code of the highest priority level of the interrupts requesting service.

Poll mode can be used when an interrupt service routine is common to several interrupt inputs. The INTA sequence is no longer required; this saves ROM space. Poll mode can also be used to expand the number of interrupts beyond 64.

Reading µPD8259A Status

The following major registers' status is available to the processor by appropriately formatting OCW3 and issuing RD command.

Interrupt Request Register

The 8-bit interrupt request register stores the interrupt levels awaiting acknowledgement. The highest priority in-service bit is reset once it has been acknowledged. Note that the interrupt mask register has no effect on the IRR. Prior to the issuing of the RD command, a WR command must be issued with OCW3. Programmable logic bits RIS and ERIS of OCW3 determine whether the IRR or ISR register is to be read. To read the contents of the IRR, ERIS must be a logic 1, and RIS a logic 0.

In-Service Register

The 8-bit in-service register stores the priorities of the interrupt levels being serviced. Assertion of an end of interrupt (EOI) updates the ISR to the next priority level. A WR command must be issued with OCW3 prior to issuing the RD command. both ERIS and RIS should be set to logic 1.

Interrupt Mask Register

The 8-bit interrupt mask register holds mask data modifying interrupt levels. A \overline{WR} pulse preceding the \overline{RD} is not necessary to read the IMR status. The IMR data is available to the data bus when \overline{RD} is asserted with A₀ at logic 1.

A single OCW3 is sufficient to enable succesive status reads providing it is of the same register. A status read is overridden by the poll mode when bits P and ERIS of OCW3 are set to logic 1.

Figure 3. Operation Command Word Format

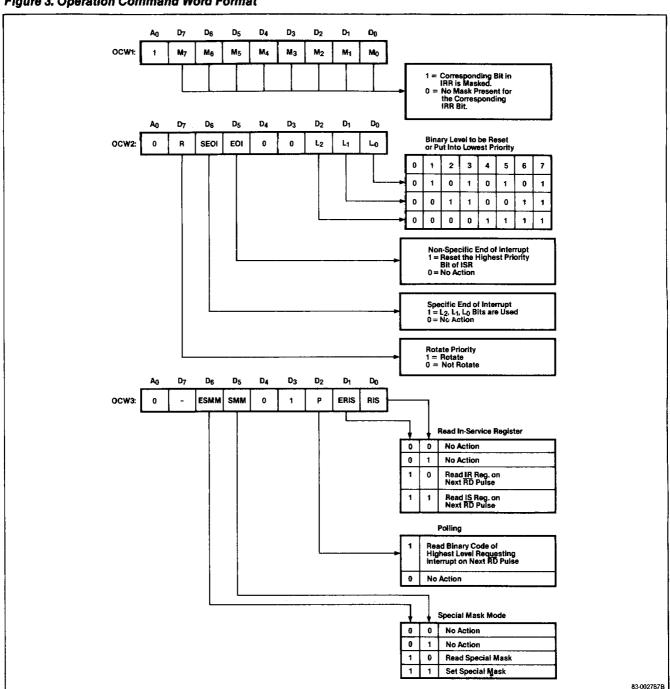

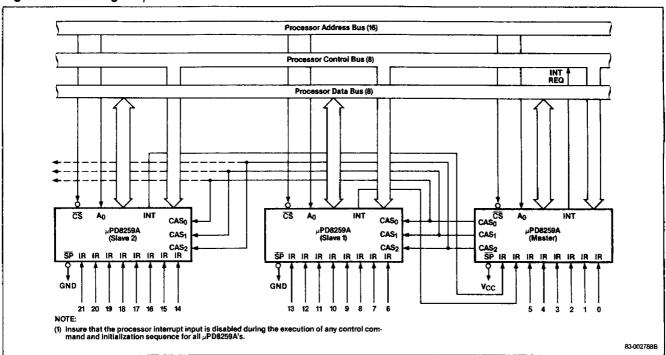

Table 6. Summary of Operation Command Word Programming

	A ₀	D ₄	D ₃				
OCW1	1	Χ	X		M ₇ -M ₀		IMR (interrupt mask register) WR loads IMR data while RD reads status
OCW2	0	0	0	R	SEOI	EOI	
				0	0	0	No action
				0	0	1	Non-specific end of interrupt
				0	1	0	No action
				0	1	1	Specific end of interrupt L ₂ , L ₁ L ₀ forms binary representation of level to be reset
				1	0	0	No action
			•	1	0	1	Rotate priority at end of inter- rupt (auto mode)
			•	1	1	0	Rotate priority, L ₂ , L ₁ , L ₀ specifies bottom priority without end of interrupt
			•	1	1	1	Rotate priority at end of inter- rupt (specific mode). L ₂ , L ₁ , L ₁ specifies bottom priority, and it is in-service register bit is reset.

	A ₀	D ₄	D3				· · · · · · · · · · · · · · · · · · ·
OCW3	0	0	1	ESMM	SMM		
				0	0	}	Special mask not affected
				0	1		Special mask not affected
				1	0		Reset special mask
				1	1		Set special mask
				ERIS	RIS		
				0	0	}	No action
				0	1		No action
				1	0		Read IR register status
				1	1		Read IS register status
