

D F 1700

Dual Channel, 8x Oversampling DIGITAL FILTER

FEATURES

- DUAL CHANNEL DIGITAL INTERPOLATION FILTERS
- ACCEPTS 16-BIT INPUT DATA
- USER-SELECTABLE FOR 16-, 18-, OR 20-BIT OUTPUT DATA
- SERIAL OUTPUT IS COMPATIBLE WITH PCM1700 AND PCM63 DACs
- PASSBAND RIPPLE < 0.00005dB
- STOPBAND ATTENUATION > 110dB
- SINGLE +5V POWER SUPPLY FOR LOW POWER DISSIPATION OF 250mW Max
- PLASTIC 28-PIN DIP AND 40-PIN SOIC PACKAGES

DESCRIPTION

The DF1700 is a high performance, 8x oversampling CMOS digital filter. This filter accepts 16-bit input data and is user-selectable for 16-, 18-, or 20-bit output data. The 8x oversampling feature converts the input data frequency (f_s) to an output data frequency of $8 \times f_s$ by digital interpolation. By providing 8x oversampled data to an audio DAC, lower order analog filters can be used at the DAC's output, thus reducing filter phase non-linearities. Oversampling with the DF1700 simultaneously improves the fidelity of the analog reconstruction and reduces analog filter complexity at the output of the DAC.

The DF1700 is available in a plastic 28-pin DIP and a 40-pin SOIC package, and is designed for compatibility with the Burr-Brown PCM1700 and PCM63 digital-to-analog converters.

Timing Waveform

The diagram shows a square wave signal labeled XTI. The signal has three horizontal levels: a high level labeled "Min 0.7V_{DD}", a middle level labeled "0.5V_{DD}", and a low level labeled "Max 0.3V_{DD}". The signal transitions between these levels. Two horizontal arrows indicate the pulse width, labeled "t_{CW}". A longer horizontal arrow indicates the cycle time, labeled "t_{CY}".

Timing Waveform

The timing diagram illustrates the relationship between the XTI clock signal and the BCKO output signal. The top two waveforms show XTI (CKDV = L) and XTI (CKDV = H) with a period T_{sys} and a reference level $V_{DD}/2$. Below, the BCKO signal is shown at 1.5V, with transitions occurring at XTI edges. The output delay t_{bdL} and t_{bdH} are indicated for the DOL, DOR, DGL, DGR, and WCKO signals. Setup and hold times t_{sbH} , t_{sbL} , t_{xbH} , and t_{xbL} are also shown.

ORDERING INFORMATION

Basic Model Number	DF1700	()
Package Code		
P: 28-pin Plastic DIP		
U: 40-pin Plastic SOIC		

ABSOLUTE MAXIMUM RATINGS

+V _{DD}	-0.3V to 7.0V
Input Voltage	-0.3 to V _{DD} + 0.3V
Soldering Temperature	255°C
Soldering Time	10s
Storage Temperature	-40°C to +125°C
Stresses above these ratings may permanently damage the device.	

ELECTROSTATIC DISCHARGE SENSITIVITY

Electrostatic discharge can cause damage ranging from performance degradation to complete device failure. Burr-Brown Corporation recommends that all integrated circuits be handled and stored using appropriate ESD protection methods.

THEORETICAL FILTER CHARACTERISTICS

PARAMETER	CHARACTERISTICS
Passband	0 - 0.4535fs
Stopband	0.5465fs - 7.4535fs
Passband Ripple	Within ± 0.00005 dB
Stopband Attenuation	More than 110dB
Group Delay Time	Constant

THEORY OF OPERATION

The DF1700 has dual filters. Each filter consists of three cascaded, 2x oversampling finite impulse response (FIR) filters as shown in Figure 1. The output of the first, 153-tap filter is again 2x oversampled by the second, 29-tap filter. This 4x oversampled data is again 2x oversampled by a third, 17-tap filter. This oversampling technique further separates the desired analog signal and the sampling frequency. This is

desirable because a low-pass filter is required at the output of a DAC to remove all unwanted frequency components caused by the sampling frequency. With the analog signal frequency further separated from the sampling frequency, a lower order analog filter with much better phase characteristics can be used at the output of the DAC without worrying about fold-over noise.

FIGURE 1. Block Diagram of Channel Filter.

FUNCTIONAL DESCRIPTION

SYSTEM CLOCK

The internal system clock of the DF1700 is generated by either a crystal oscillator connected across pins XTI and XTO driving the internal clock generator, or an external clock applied at pin XTI. Four different XTI clock frequencies can be obtained with the control of pins CKDV and CKSL. This

will provide the correct clock period of the internal system clock as indicated in Table I. For XTI clock frequencies of 384fs and 512fs, the clock is divided by two for internal use. The system clock signal of the same frequency as pin XTI is available at pin CKO.

DATA

Serial Data Input

The 16-bit input data format is two's complement and MSB first. The serial data input timing is the rising edge of BCKI (Figure 2). Consequently the input serial data must be changed at the falling edge of BCKI. The input data is latched to the internal register at the edge of LRCI.

Serial Data Output

The serial data output mode is selected by pins $\overline{OW18}$ and $\overline{OW20}$ as shown in Table II.

The output data format is MSB first and either two's complement or complementary offset binary (COB). The format of output data is selected by the COB pin:

$\overline{COB} = H$ Two's complement
 $\overline{COB} = L$ Complement Offset Binary (COB)

The output data from the DF1700 can be fed directly to the data inputs of either the PCM1700 or PCM63 with the BCKO clock output serving as the input clock to these DACs. The data bits will be clocked into the DAC on the rising edges of BCKO (Figure 3).

CONDITION		XTI CLOCK (F_{xt})	CLOCK PERIOD OF INTERNAL SYSTEM CLOCK
CKDV	CKSL		
H	H	192fs	$1/F_{xt}$
H	L	256fs	$1/F_{xt}$
L	H	384fs	$2/F_{xt}$
L	L	512fs	$2/F_{xt}$

NOTE: fs = sampling frequency.

$\overline{OW18}$	$\overline{OW20}$	NO. OF OUTPUT DATA BITS
H	H	16
L	H	18
H	L	20

TABLE II. Programming the Number of Output Data Bits.

CLOCK SYNCHRONIZATION

The internal clock for the arithmetic circuitry and output interface is derived by the system clock from the XTI pin, and is independent of the input circuitry timing from the BCKI and LRCI input clocks. There are two synchronization modes: the Free-Running Mode and the Forced Synchronization Mode.

FIGURE 2. Input Timing Waveforms for Clocking Data into the DF1700.

FIGURE 3. Output Data Timing Waveforms.

Free-Running Mode (SYN = H)

No adjustment of the internal clock takes place for phase differences between the internal clock and the LRCI clock of up to $\pm 3/8$ of the input data sample period ($1/f_s$). Hence, internal timing is not affected even if jitter is present on the LRCI clock input, and no jitter or timing glitches appear on the data output. If the clock phase differences exceed the $\pm 3/8 f_s$ limit, or if the RESET function is executed, the internal clock is synchronized to the rising edge of LRCI.

Forced Synchronization Mode (SYN = L)

In this mode the internal clock is resynchronized at each rising edge of LRCI. Note that device misoperation may occur if jitter in the LRCI input shortens the LRCI period below the required system clock period. Furthermore, if the LRCI period is too long, internal arithmetic operations will function correctly, but output timing is adversely affected. The internal timing clock derived from the system clock is available at the FSCO pin.

FIGURE 4. System Reset Circuit.

SYSTEM RESET (SYN = H). It is not necessary to reset in the forced synchroThe RESET function is useful for synchronizing the internal nization mode. Reset is also not required if the output timing arithmetic circuitry and output section clock with the LRCI needs not be synchronized with LRCI. Figure 4 shows the external input clock when operating in the free-running mode connection to reset the DF1700 on power-up.

TIMING DIAGRAMS

APPLICATIONS

The most common application for the DF1700 is in high performance digital audio playback such as compact disc players. Digital information from a compact disc is often formatted using a digital interface format receiver chip (DIFRC). The DF1700 can be interfaced directly to the output of many popular DIFRCs as shown in Figure 5.

The fs data stream which has been formatted by the DIFRC is 8x oversampled by the DF1700 and separated into left and right channel data for input to the PCM1700 DAC (Figure 6). The analog stereo outputs from the PCM1700 each pass

through a three pole Generalized Immittance Converter (GIC) low-pass filter which has extremely low distortion and negligible phase shift. An evaluation board, the DEM 1143, is available from Burr-Brown for the PCM 1700/DF1700. This board has the features mentioned above as well as an AES/EBU interface and breadboard area for user experimentation. Figure 7 shows a similar circuit diagram with the DF1700 providing 8x oversampled data to a pair of PCM63 DACs.
