

Non-Isolated Buck APFC Offline LED Power Switch

FEATURES

- Active PFC for High PF and Low THD
- PF>0.9 with Universal Input
- Built-in HV Startup and IC Power Supply Circuit
- Internal 550V Power MOSFET
- Quasi-Resonant for High Efficiency
- ±1% CC Regulation
- Very Low VDD Operation Current
- Excellent Line and Load Regulation
- LED Open/Short Protection
- Build in Protections:
 - Output Over Voltage Protection (OVP)
 - Cycle-by-Cycle Current Limiting (OCP)
 - Leading Edge Blanking (LEB)
 - LED Open/Short Protection
 - On-Chip Thermal Foldback (OTP)
- Available in SOP-7 Package

GENERAL DESCRIPTION

DP9126IX1 series are a highly integrated power switch with constant current (CC) control for LED lighting applications. The IC utilizes Quasi-Resonant (QR) Buck topology with active PFC control for high PF, low THD, and high efficiency.

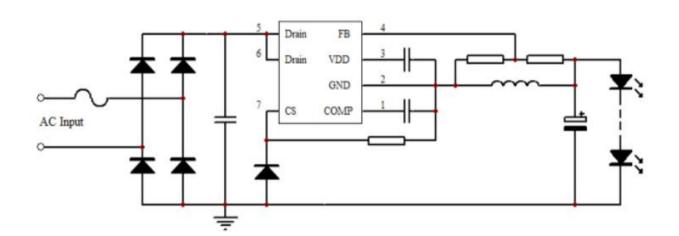

DP9126IX1 integrates 550V power MOSFET with high voltage startup and IC power supply circuit, which requires very few external components. The IC senses the inductor current during the whole switching cycle, which can achieve high precision CC control with excellent line and load regulation.

DP9126IX1 integrates functions and protections of Under Voltage Lockout (UVLO), Cycle-by-cycle Current Limiting (OCP), Thermal Foldack (OTP), Output Over Voltage Protection (OVP), LED Open/Short Protection, etc.

APPLICATIONS

LED Lighting

TYPICAL APPLICATION CIRCUIT

Pin Configuration

Marking Information

SOP-7

Mark:

1. The first or two XX:

Present production version, like 1、 A1、 B1、 C1;

2. The other X;

Present batch ID;

Output Power Table

Part Number	Package	Maximum Output Current (90-265Vac)		
i ait Nullibei	i ackage	36V output	72V output	
DP9126I	SOP-7	250 mA	180 mA	
DP9126IA1	SOP-7	330 mA	240 mA	
DP9126IB1	SOP-7	400 mA	270 mA	
DP9126IC1	SOP-7	420 mA	300 mA	

Pin Description

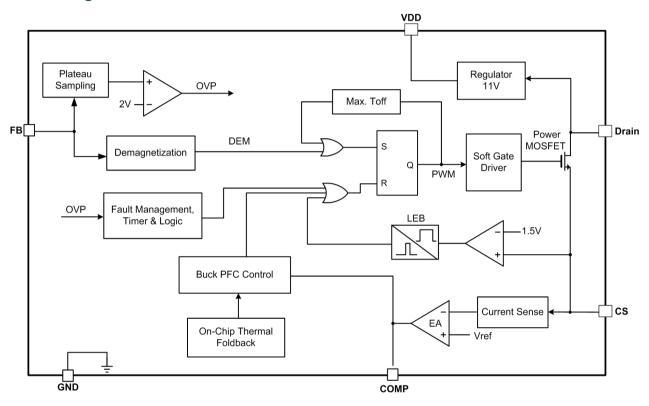

Pin Number	Pin Number	I/O	Description
1	СОМР	I	Loop Compensation Pin. Connect a capacitor between this pin and GND for CC regulation
2	GND	Р	IC Ground Pin
3	VDD	Р	IC Power Supply Pin
4	FB	I	This pin detects the inductor demagnetization signal and the output voltage
5,6	Drain	Р	Internal Power MOSFET Drain Pin
7	CS	I	Current Sense Input Pin

Note 1. Stresses listed as the above "Maximum Ratings" may cause permanent damage to the device. These are for stress ratings. Functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to maximum rating conditions for extended periods may remain possibility to affect device reliability.

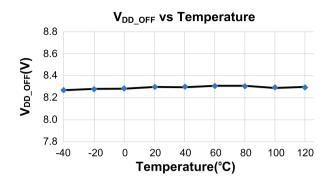

Note 2. The device is not guaranteed to function outside its operating conditions.

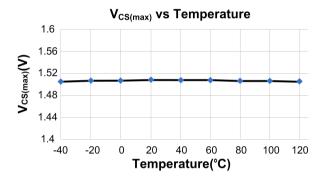

Note 3. Guaranteed by the Design.

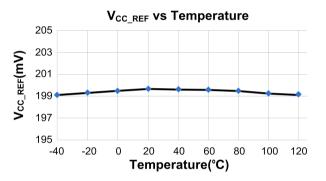

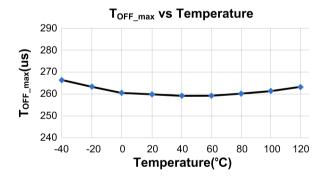

Characterization Plots

Operation Description

DP9126IX1 series are a highly integrated power switch with constant current (CC) control for LED lighting applications. The IC utilizes Quasi-Resonant (QR) Buck topology with active PFC control for high PF, low THD, and high efficiency.

11V Regulator

In DP9126IX1, the 11V regulator charges VDD hold-up capacitor to 11V by drawing a current from the voltage on the Drain pin, whenever the internal power MOSFET is off. When the power MOSFET is on, the charging device runs off of the energy stored in the VDD hold-up capacitor. Extremely low IC power consumption allows DP9126IX1 to operate continuously from the current drawn from the Drain pin. A capacitor value about 1uF is sufficient for both high frequency decoupling and energy storage.

System Start-Up Operation

After system power up, VDD hold up capacitor is charged by the internal HV startup circuit through Drain pin. When VDD pin voltage reaches the turn on threshold, the IC begins working. The COMP pin is pulled up to 0.7V quickly, then the IC begins to work at low switching frequency (typical 3.5KHz), the COMP pin voltage rises up gradually, thus the inductor peak current also rises up. The LED current hence achieves a soft start without over shoot.

Constant Current (CC) Control

DP9126IX1 adopts floating ground structure. The inductor current is sensed during the whole switching cycle. The IC can accurately control the output current by the internal current feedback control loop. The output mean current in constant current (CC) mode can be expressed as:

$$I_{CC_OUT}(mA) = \frac{V_{CC_REF}}{R_{CS}} = \frac{200mV}{Rcs(\Omega)}$$

In the equation above,

Rcs--- the sensing resistor connected between CS and GND.

Leading Edge Blanking (LEB)

Each time the power MOSFET is switched on, a turn-on spike occurs across the sensing resistor. The spike is caused by primary side capacitance and secondary side rectifier reverse recovery. To avoid premature termination of the switching pulse, an internal leading edge blanking circuit is built in. During this blanking period (300ns, typical), the PWM comparator is disabled and cannot switch off the gate driver.

Demagnetization Detection

DP9126IX1 senses the output current zero crossing information through the external resistor feedback network. If FB pin voltage drops below 0.2V, an internal DEM comparator is triggered and a new switching cycle is initiated following the DEM triggering. The power MOSFET is always turned on with zero inductor current such that the turn-on loss and noise can be minimized.

Minimum and Maximum OFF Time

In DP9126IX1, a minimum OFF time (typically 2us) is implemented to suppress ringing when the power MOSFET is off. The minimum OFF time is necessary in applications where the transformer has a large leakage inductance. The maximum OFF time in DP9126IX1 is typically 270us.

Output Over Voltage Protection (OVP)

In DP9126IX1, the output OVP is integrated by

plateau sampling the auxiliary winding in the PWM OFF state. If the sampled plateau voltage exceeds the OVP threshold (2V), an internal counter starts counting subsequent OVP events. If OVP events are detected in successive 3 cycles, the controller assumes a true OVP and it stops all switching operations, as shown in Fig.1. The counter has been added to prevent incorrect OVP detection which might occur during ESD or lightning events. If the output voltage exceeds the OVP threshold less than 3 successive cycles, the internal counter will be cleared and no fault is asserted. Output OVP is auto-recovery mode protection.

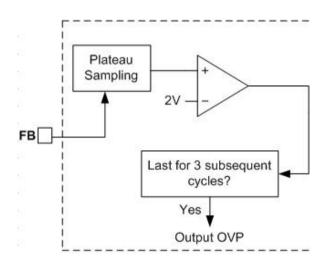

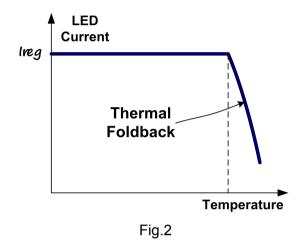

Fig.1

Auto-Restart Protection

In the event of LED open loop condition/output OVP protection, the IC enters into auto-restart and VDD oscillation mode begins, wherein the power MOSFET is disabled. In VDD oscillation mode, the VDD hold-up capacitor voltage will periodically ramp up and down between 11.5V and 8.3V with a digital counter counting the oscillation cycle. When 8 cycles had been counted, the IC will reset and start up the system again. However, if the fault still exists, the system will experience the above mentioned process. If the fault has gone, the system will resume normal operation.

On Chip Thermal Foldback (OTP)

DP9126IX1 integrates thermal foldback function. When the IC temperature is over 150 °C, the system output regulation current is gradually reduced, as shown in Fig.2. Thus, the output power and thermal dissipation are also reduced. In this way, the system temperature is limited and system reliability is also improved.

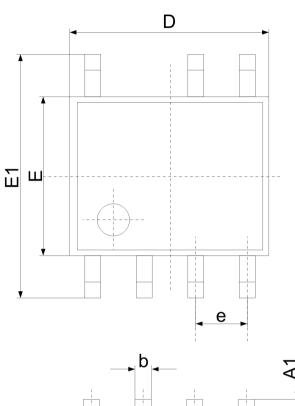

Soft Totem-Pole Gate Driver

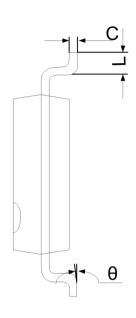

DP9126IX1 has a soft totem-pole gate driver with optimized EMI performance.
