1 General Description

The EM78P346N is an 8-bit microprocessor designed and developed with low-power and high-speed CMOS technology. It has as an on-chip 4K×13-bit Electrical One Time Programmable Read Only Memory (OTP-ROM). It provides a protection bit to prevent intrusion of user's OTP memory code. Three Code option bits are also available to meet user's requirements.

With its enhanced OTP-ROM feature, the device provides a convenient way of developing and verifying user's programs. Moreover, this OTP device offers the advantages of easy and effective program updates, using development and programming tools. User can avail of the ELAN Writer to easily program his development code.

6 Function Description

6.1 Operational Registers

6.1.1 R0 (Indirect Address Register)

R0 is not a physically implemented register. It is used as an indirect address pointer. Any instruction using R0 as a pointer, actually accesses the data pointed by the RAM Select Register (R4).

6.1.2 R1 (Time Clock/Counter)

- Incremented by an external signal edge through the TCC pin, or by the instruction cycle clock.
- External signal of TCC trigger pulse width must be greater than one instruction.
- The signals to increase the counter are determined by Bit 4 and Bit 5 of the CONT register.
- Writable and readable as any other registers.

6.1.3 R2 (Program Counter) and Stack

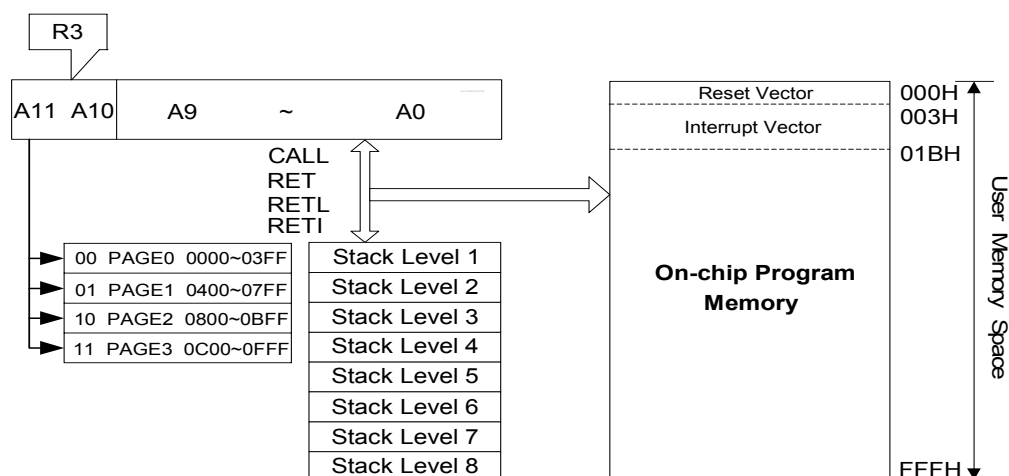

Figure 6-1 Program Counter Organization

- R2 and hardware stacks are 12-bit wide. The structure is depicted in the table under Section 6.1.3.1 *Data Memory Configuration* (next section).
- The configuration structure generates 4K×13 bits on-chip ROM addresses to the relative programming instruction codes. One program page is 1024 words long.
- The contents of R2 are all set to "0"s when a reset condition occurs.
- "JMP" instruction allows direct loading of the lower 10 program counter bits. Thus, "JMP" allows PC to jump to any location within a page.

- "CALL" instruction loads the lower 10 bits of the PC, and then PC+1 is pushed onto the stack. Thus, the subroutine entry address can be located anywhere within a page.
- "RET" ("RETL k", "RETI") instruction loads the program counter with the contents of the top of stack.
- "ADD R2, A" allows a relative address to be added to the current PC, and the ninth and above bits of the PC will increase progressively.
- "MOV R2, A" allows loading of an address from the "A" register to the lower 8 bits of the PC, and the ninth and tenth bits (A8 ~ A9) of the PC will remain unchanged.
- Any instruction (except "ADD R2, A") that is written to R2 (e.g., "MOV R2, A", "BC R2, 6" etc.) will cause the ninth bit and the tenth bit (A8 ~ A9) of the PC to remain unchanged.
- In the case of EM78P346N, the most two significant bits (A11 and A10) will be loaded with the content of PS1 and PS0 in the status register (R3) upon execution of a "JMP", "CALL", or any other instructions set which write to R2.
- All instructions are single instruction cycle (fclk/2 or fclk/4) except for the instructions that are written to R2. Note that these instructions need one or two instructions cycle as determined by Code Option Register CYES bit.

6.3 TCC/WDT and Prescaler

There are two 8-bit counters available as prescalers for the TCC and WDT respectively. The PST0 ~ PST2 bits of the CONT register are used to determine the ratio of the TCC prescaler, and the PWR0 ~ PWR2 bits of the IOCE0 register are used to determine the prescaler of WDT. The prescaler counter is cleared by the instructions each time such instructions are written into TCC. The WDT and prescaler will be cleared by the "WDTC" and "SLEP" instructions. Figure 6-3 depicts the block diagram of TCC/WDT.

TCC (R1) is an 8-bit timer/counter. The TCC clock source can be internal clock or external signal input (edge selectable from the TCC pin). If TCC signal source is from internal clock, TCC will increase by 1 at main oscillator (without prescaler). Referring to Figure 6-3, if the TCC signal source is from the external clock input, TCC will increase by 1 at every falling edge or rising edge of the TCC pin. TCC pin input time length (kept at High or Low level) must be greater than 1CLK.

NOTE

The internal TCC will stop running when sleep mode occurs. However, during AD conversion, when TCC is set to "SLEP" instruction, if the ADWE bit of RE register is enabled, the TCC will keep on running.

The watchdog timer is a free running on-chip RC oscillator. The WDT will keep on running even when the oscillator driver has been turned off (i.e., in sleep mode). During normal operation or sleep mode, a WDT time-out (if enabled) will cause the device to reset. The WDT can be enabled or disabled at any time during normal mode through software programming. Refer to WDTE bit of IOCE0 register (Section

6.2.10 IOCE0 (WDT Control Register). With no prescaler, the WDT time-out duration is approximately 18ms.¹

6.4 I/O Ports

The I/O registers (Port 5, Port 6, Port 7) are bidirectional tri-state I/O ports. The Pull-high, Pull-down, and Open-drain functions can be set internally by IOCB0, IOCC0, and IOCD0 respectively. Port 6 features an input status change interrupt (or wake-up) function. Each I/O pin can be defined as "input" or "output" pin by the I/O control registers (IOC50 ~ IOC70). The I/O registers and I/O control registers are both readable and writable. The I/O interface circuits for Port 5, Port 6, and Port 7 are illustrated in Figures 6-4, 6-5, and 6-6 respectively (see next page). Port 6 with Input Change Interrupt/Wake-up is shown in Figure 6-6.

6.5 Reset and Wake-up

6.5.1 Reset and Wake-up Operation

A reset is initiated by one of the following events:

1. Power-on reset
2. /RESET pin input "low"
3. WDT time-out (if enabled)

The device is kept in a reset condition for a duration of approximately 18ms² after a reset is detected. When in LXT mode, the reset time is 2s~3s. Once reset occurs, the following functions are performed (the initial address is 000h):

- The oscillator continues running, or will be started (if in sleep mode).
- The Program Counter (R2) is set to all "0".
- All I/O port pins are configured as input mode (high-impedance state).
- The Watchdog Timer and prescaler are cleared.
- When power is switched on, the upper three bits of R3 and upper two bits of R4 are cleared.
- The CONT register bits are set to all "1" except for Bit 6 (INT flag).

² VDD=5V, WDT Time-out period = 16.5ms ± 5%.
VDD=3V, WDT Time-out period = 18ms ± 5%.

- The IOCB0 register bits are set to all "1"
- The IOCC0 register bits are set to all "1"
- The IOCD0 register bits are set to all "1"
- Bit 7 of the IOCE0 register is set to "1", and Bits 6~0 are cleared
- Bits 0~6 of RF register and Bits 0~6 of IOCF0 register are cleared

Executing the "SLEP" instruction will assert the sleep (power down) mode. While entering sleep mode, the Oscillator, TCC, Timer 1, Timer 2, and Timer 3 are stopped. The WDT (if enabled) is cleared but keeps on running.

The controller can be awakened by:

Case 1 External reset input on /RESET pin

Case 2 WDT time-out (if enabled)

Case 3 Port 6 input status change (if ICWE is enabled)

Case 4 Comparator output status change (if CMPWE is enabled)

Case 5 AD conversion completed (if ADWE is enabled)

Case 6 Low Voltage Detector (if LVDWE is enabled)

The first two cases (1 & 2) will cause the EM78P346N to reset. The T and P flags of R3 can be used to determine the source of the reset (wake-up). Cases 3, 4, 5, & 6 are considered a continuation of program execution and a global interrupt ("ENI" or "DISI" being executed) determines whether or not the controller branches to the interrupt vector following wake-up. If ENI is executed before SLEP, the instruction will begin to execute from address 0x06 (Case 3), 0x0F (Case 4), 0x0C (Case 5), and 0x1B (Case 6) after wake-up. If DISI is executed before SLEP, the execution will restart from the instruction next to SLEP after wake-up.

Only one of Cases 1 to 6 can be enabled before entering into sleep mode. That is:

Case [a] If WDT is enabled before SLEP, all of the RE bit is disabled. Hence, the EM78P346N can be awakened only with Case 1 or Case 2. Refer to the section on Interrupt (Section 6.6) for further details. In High Crystal mode, wake-up time is 0.8ms (HXT2, 4MHz), no matter what the oscillator type or mode is (except when it's in low Crystal mode). In low Crystal mode, wake-up time is 2s~3s.

Case [b] If Port 6 Input Status Change is used to wake up the EM78P346N and the ICWE bit of the RE register is enabled before SLEP, WDT must be disabled. Hence, the EM78P346N can be awakened only with Case 3. Wake-up time is dependent on oscillator mode. In RC mode the reset time is 32 clocks (for stable oscillators). In High Crystal mode, wake-up time is 0.8ms (HXT2, 4MHz), no matter what the oscillator type or mode is (except when it's in low Crystal mode). In low Crystal mode, wake-up time is 2s~3s.

Case [c] If Comparator output status change is used to wake up the EM78P346N and the CMPWE bit of the RE register is enabled before SLEP, WDT must be disabled by software. Hence, the EM78P346N can be awakened only with Case 4.

Wake-up time is dependent on oscillator mode. In RC mode the reset time is 32 clocks (for stable oscillators). In High Crystal mode, wake-up time is 0.8ms (HXT2, 4MHz), no matter what the oscillator type or mode is (except when it's in low Crystal mode). In low Crystal mode, wake-up time is 2s~3s.

Case [d] If AD conversion completed status is used to wake up the EM78P346N and ADWE bit of the RE register is enabled before SLEP, WDT must be disabled by software. Hence, the EM78P346N can be awakened only with Case 5. The wake-up time is 15 TAD (ADC clock period).

Case [e] If Low voltage detector is used to wake up the EM78P346N and LVDWE bit of BANK0-RE register is enabled before SLEP, WDT must be disabled by software. Hence, the EM78P346N can be awakened only with Case 6. Wake-up time is dependent on oscillator mode. In RC mode the reset time is 32 clocks (for stable oscillators). In High Crystal mode, wake-up time is 0.8ms (HXT2, 4MHz), no matter what the oscillator type or mode is (except when it's in low Crystal mode). In low Crystal mode, wake-up time is 2s~3s.

If Port 6 Input Status Change Interrupt is used to wake up the EM78P346N (as in Case [b] above), the following instructions must be executed before SLEP:

```
BC          R3, 7          ; Select Segment 0
MOV         A, @001110xxb  ; Select WDT prescaler and Disable WDT
IOW         IOCE0
WDTC                    ; Clear WDT and prescaler
MOV         R6, R6        ; Read Port 6
ENI (or DISI)          ; Enable (or disable) global interrupt
MOV         A, @00000x1xb  ; Enable Port 6 input change wake-up bit
MOV         RE
MOV         A, @00000x1xb  ; Enable Port 6 input change interrupt
IOW         IOCF0
SLEP                    ; Sleep
```

Similarly, if the Comparator Interrupt is used to wake up the EM78P346N (as in Case [c] above), the following instructions must be executed before SLEP:

```
BC          R3, 7          ; Select Segment 0
MOV         A, @xxxxxxx10b ; Select an comparator and P60 act as CO pin
IOW         IOCA0
MOV         A, @001110xxb  ; Select WDT prescaler and Disable WDT
IOW         IOCE0
WDTC                    ; Clear WDT and prescaler
ENI (or DISI)          ; Enable (or disable) global interrupt
MOV         A, @000001xxb  ; Enable comparator output status change
                           ; wake-up bit
MOV         RE
MOV         A, @000001xxb  ; Enable comparator output status change
IOW         IOCF0          ; interrupt
SLEP                    ; Sleep
```

6.6 Interrupt

The EM78P346N has six interrupts as listed below:

1. TCC overflow interrupt
2. Port 6 Input Status Change Interrupt
3. External interrupt [(P50, /INT) pin]
4. Analog to Digital conversion completed
5. When TMR1/TMR2/TIMER3 matches with PRD1/PRD2/PRD3 respectively in PWM
6. When the comparators output changes (for EM78P346N-20Pin and 24Pin only)
7. Low voltage detector interrupt

Before the Port 6 Input Status Change Interrupt is enabled, reading Port 6 (e.g., "MOV R6, R6") is necessary. Each Port 6 pin will have this feature if its status changes. Port 6 Input Status Change Interrupt will wake up the EM78P346N from sleep mode if it is enabled prior to going into sleep mode by executing SLEP. When wake up occurs, the controller will continue to execute the succeeding program if the global interrupt is disabled. If enabled, it will branch out to the interrupt Vector 006H.

External interrupt equipped with digital noise rejection circuit (input pulse less than 8 system clock time) is eliminated as noise. However, under Low Crystal oscillator (LXT) mode the noise rejection circuit will be disabled. Edge selection is possible with INTE of CONT. When an interrupt is generated by the External interrupt (when enabled), the next instruction will be fetched from Address 003H. Refer to the Word 1 Bits 8~7 (Section 6.14.2, *Code Option Register (Word 1)*) for digital noise rejection definition.

RF is the interrupt status register that records the interrupt requests in the relative flags/bits. IOCF0 is an interrupt mask register. The global interrupt is enabled by the ENI instruction and is disabled by the DISI instruction. When one of the interrupts (when enabled) occurs, the next instruction will be fetched from interrupt vector address. Once in the interrupt service routine, the source of an interrupt can be determined by polling the flag bits in RF. The interrupt flag bit must be cleared by instructions before leaving the interrupt service routine to avoid recursive interrupts.

The flag (except ICIF bit) in the Interrupt Status Register (RF) is set regardless of the status of its mask bit or of the ENI execution. Note that the result of RF will be the logic AND of RF and IOCF0 (refer to the figure). The RETI instruction ends the interrupt routine and enables the global interrupt (the ENI execution).

During the power source unstable situation, such as external power noise interference or EMS test condition, it will cause the power to vibrate fiercely. At the time wherein the Vdd is unsettled, the voltage supply may be below working voltage. When the system supply voltage Vdd is below the working voltage, the IC kernel must keep all register status automatically.

When an interrupt is generated by the Timer clock/counter (when enabled), the next instruction will be fetched from Address 009, 012, 015, and 018H (TCC, Timer 1, Timer 2, and Timer 3 respectively).

When an interrupt is generated during a Low Voltage Detect (when enabled), the next instruction will be fetched from Address 01 by the Low Voltage Detector.

Before an interrupt subroutine is executed, the contents of ACC and the R3 and R4 registers will be saved by the hardware. If another interrupt occurs, the ACC, R3, and R4 will be replaced by the new interrupt. After the interrupt service routine is completed, the ACC, R3, and R4 registers are restored.

During the power source unstable situation, such as external power noise interference or EMS test condition, such will cause the power to vibrate fiercely. At the time the Vdd is unsettled, the voltage supply may be below working voltage. When the system voltage supply Vdd is below the working voltage, the IC kernel must keep all register status automatically.

6.7 Analog-To-Digital Converter (ADC)

The analog-to-digital circuitry consists of an 8-bit analog multiplexer; three control registers (AISR/R8, ADCON/R9, & ADOC/RA), three data registers (ADDATA1/RB, ADDATA1H/RC, & ADDATA1L/RD) and an ADC with 12-bit resolution as shown in the functional block diagram below. The analog reference voltage (Vref) and the analog ground are connected via separate input pins.

The ADC module utilizes successive approximation to convert the unknown analog signal into a digital value. The result is fed to the ADDATA, ADDATA1H and ADDATA1L. Input channels are selected by the analog input multiplexer via the ADCON register Bits. Connecting to external VREF is more accurate than connection to the internal VDD.

NOTE

The P53/PWM3/VREF pin cannot be applied to PWM3 and VREF at the same time. If P53/PWM3/VREF functions as VREF analog input pin, then PWM3E must be "0".

These bits can only be changed when the ADIF bit and the ADRUN bit are both LOW.

6.7.2 ADC Data Register (ADDATA/RB, ADDATA1H/RC, ADDATA1L/RD)

When the AD conversion is completed, the result is loaded to the ADDATA, ADDATA1H and ADDATA1L registers. The ADRUN bit is cleared, and the ADIF is set.

6.7.3 ADC Sampling Time

The accuracy, linearity, and speed of the successive approximation of AD converter are dependent on the properties of the ADC and the comparator. The source impedance and the internal sampling impedance directly affect the time required to charge the sample holding capacitor. The application program controls the length of the sample time to meet the specified accuracy. Generally speaking, the program should wait for 2 μ s for each K Ω of the analog source impedance and at least 2 μ s for the low-impedance source. The maximum recommended impedance for analog source is 10K Ω at Vdd=5V. After the analog input channel is selected, this acquisition time must be done before the conversion is started.

6.7.4 AD Conversion Time

CKR1 and CKR0 select the conversion time (Tct), in terms of instruction cycles. This allows the MCU to run at the maximum frequency without sacrificing the AD conversion accuracy. For the EM78P346N, the conversion time per bit is about 4 μ s. The table below shows the relationship between Tct and the maximum operating frequencies.

CKR1:CKR0	Operation Mode	Max. Operation Frequency	Max. Conversion Rate/Bit	Max. Conversion Rate
00	Fosc/16	4MHz	250kHz (4 μ s)	15 \times 4 μ s=60 μ s (16.7kHz)
01	Fosc/4	1MHz	250kHz (4 μ s)	15 \times 4 μ s=60 μ s (16.7kHz)
10	Fosc/64	16MHz	250kHz (4 μ s)	15 \times 4 μ s=60 μ s (16.7kHz)
11	Fosc/8	2MHz	250kHz (4 μ s)	15 \times 4 μ s=60 μ s (16.7kHz)

NOTE

- Pin not used as an analog input pin can be used as regular input or output pin.
- During conversion, do not perform output instruction to maintain precision for all of the pins.

6.7.5 ADC Operation during Sleep Mode

In order to obtain a more accurate ADC value and reduce power consumption, the AD conversion remains operational during sleep mode. As the SLEP instruction is executed, all the MCU operations will stop except for the Oscillator, TCC, Timer 1, Timer 2, Timer 3, and AD conversion.

The AD Conversion is considered completed as determined by:

1. The ADRUN bit of R9 register is cleared to "0".
2. Waking up from AD conversion (where it remains in operation during sleep mode).

The results are fed into the ADDATA, ADDATA1H, and ADDATA1L registers when the conversion is completed. If the ADWE is enabled, the device will wake up. Otherwise, the AD conversion will be shut off, no matter what the status of the ADPD bit is.

6.7.6 Programming Process/Considerations

6.7.6.1 Programming Process

Follow these steps to obtain data from the ADC:

1. Write to the eight bits (ADE7: ADE0) on the R8 (AISR) register to define the characteristics of R6 (digital I/O, analog channels, or voltage reference pin)
2. Write to the R9/ADCON register to configure the AD module:
 - a) Select ADC input channel (ADIS2 : ADIS0)
 - b) Define AD conversion clock rate (CKR1 : CKR0)
 - c) Select the VREFS input source of the ADC
 - d) Set the ADPD bit to 1 to begin sampling
3. Set the ADWE bit, if the wake-up function is employed
4. Set the ADIE bit, if the interrupt function is employed
5. Write "ENI" instruction, if the interrupt function is employed
6. Set the ADRUN bit to 1
7. Write "SLEP" instruction or Polling.
8. Wait for wake-up or for the ADRUN bit to be cleared to "0".
9. Read the ADDATA or ADDATA1H and ADDATA1L conversion data registers. If the ADC input channel changes at this time, the ADDATA, ADDATA1H, and ADDATA1L values can be cleared to '0'.
10. Clear the interrupt flag bit (ADIF).
11. For next conversion, go to Step 1 or Step 2 as required. At least two Tct is required before the next acquisition starts.

NOTE

In order to obtain accurate values, it is necessary to avoid any data transition on I/O pins during AD conversion.

6.8 Dual Sets of PWM (Pulse Width Modulation)

6.8.1 Overview

In PWM mode, PWM1, PWM2, and PWM3 pins produce up to a 10-bit resolution PWM output (see the functional block diagram below). A PWM output consists of a time period and a duty cycle, and it keeps the output high. The baud rate of the PWM is the inverse of the time period. Figure 6-12 (*PWM Output Timing*) depicts the relationships between a time period and a duty cycle.

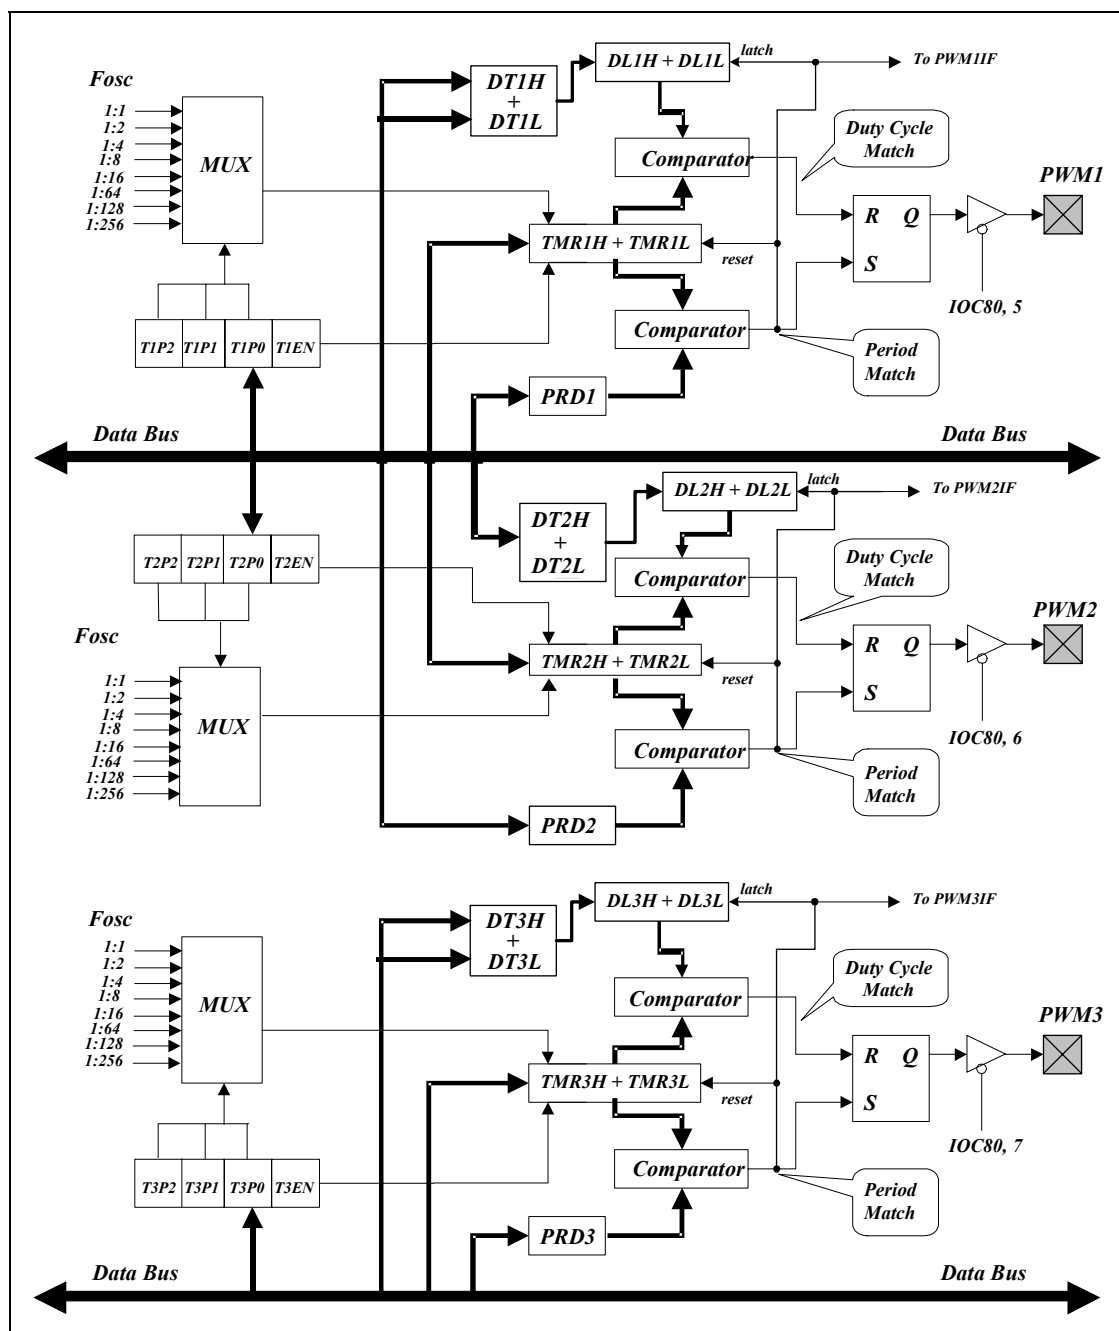

Figure 6-12 The Three PWMs Functional Block Diagram

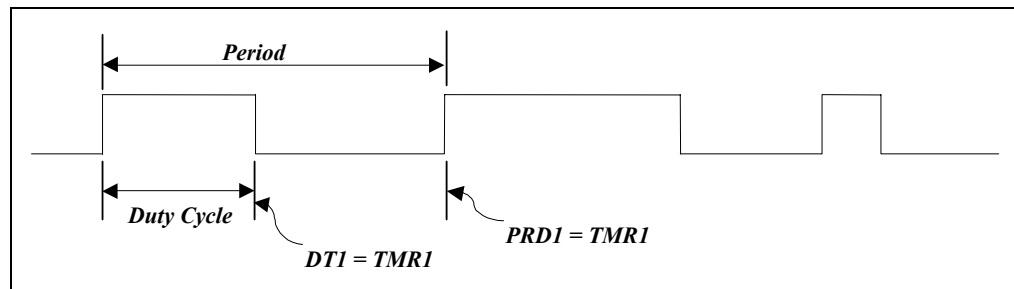

Figure 6-13 PWM Output Timing

6.8.2 Increment Timer Counter (TMRX: TMR1H/TWR1L, TMR2H/TWR2L, or TMR3H/TWR3L)

TMRX are 10-bit clock counters with programmable prescalers. They are designed for the PWM module as baud rate clock generators. TMRX can be read only. If employed, they can be turned off for power saving by setting the T1EN bit [IOC80<3>], T2EN bit [IOC90<6>] or T3EN bit [IOC90<7>] to 0.

6.8.3 PWM Time Period (PRDX: PRD1 or PRD2)

The PWM time period is defined by writing to the PRDX register. When TMRX is equal to PRDX, the following events occur on the next increment cycle:

- TMRX is cleared
- The PWMX pin is set to 1
- The PWM duty cycle is latched from DT1/DT2/DT3 to DL1/DL2/DL3

NOTE

The PWM output will not be set, if the duty cycle is 0

- The PWMXIF pin is set to 1

The following formula describes how to calculate the PWM time period:

$$\text{PERIOD} = (\text{PRDX} + 1) * (1/\text{Fosc}) * (\text{TMRX prescale value})$$

Example:

$$\text{PRDX}=49; \text{Fosc}=4\text{MHz}; \text{TMRX} (0, 0, 0) = 1:1, \text{ then PERIOD} = (49 + 1) * (1/4\text{M}) * 1 = 12.5\mu\text{s}$$

6.8.4 PWM Duty Cycle (DTX: DT1H/ DT1L, DT2H/ DT2L and DT3H/DT3L; DLX: DL1H/DL1L, DL2H/DL2L and DL3H/DL3L)

The PWM duty cycle is defined by writing to the DTX register, and is latched from DTX to DLX while TMRX is cleared. When DLX is equal to TMRX, the PWMX pin is cleared. DTX can be loaded anytime. However, it cannot be latched into DLX until the current value of PRDX is equal to TMRX.

The following formula describes how to calculate the PWM duty cycle:

$$\text{Duty Cycle} = (\text{DTX}) * (1/\text{Fosc}) * (\text{TMRX prescale value})$$

Example:

DTX=10; Fosc=4MHz; TMRX (0, 0, 0) = 1:1, then Duty Cycle=10 * (1/4M)
* 1 = 2.5us

6.8.5 Comparator X

Changing the output status while a match occurs, will set the TMRXIF flag at the same time.

6.8.6 PWM Programming Process/Steps

Load PRDX with the PWM time period.

1. Load DTX with the PWM Duty Cycle.
2. Enable interrupt function by writing IOCF0, if required.
3. Set PWMX pin to be output by writing a desired value to IOC80.
4. Load a desired value to IOC51 with TMRX prescaler value and enable both PWMX and TMRX.

6.9 Timer

6.9.1 Overview

Timer 1 (TMR1), Timer 2 (TMR2), and Timer 3 (TMR3) (TMRX) are 10-bit clock counters with programmable prescalers. They are designed for the PWM module as baud rate clock generators. TMRX can be read only. The Timer 1, Timer 2, and Timer 3 will stop running when sleep mode occurs with AD conversion not running. However, if AD conversion is running when sleep mode occurs, the Timer 1, Timer 2 and Timer 3 will keep on running.

6.9.2 Function Description

The following figure shows the TMRX block diagram followed by descriptions of its signals and blocks:

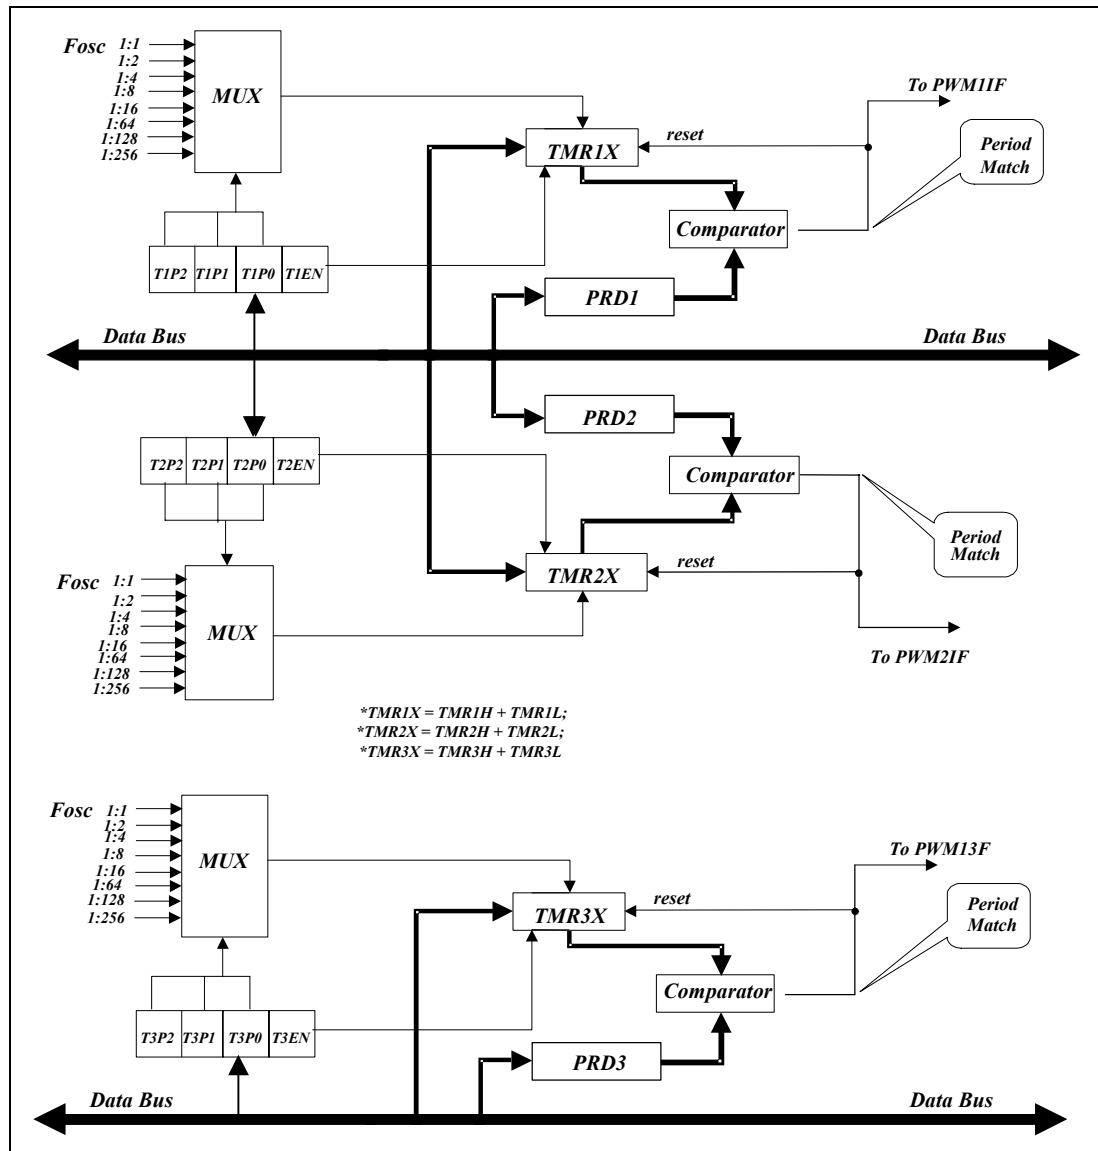

Figure 6-14 TMRX Block Diagram

Fosc: Input clock.

Prescaler (T1P2, T1P1 and T1P0 / T2P2, T2P1 and T2P0 / T3P2, T3P1 and T3P0):

The options 1:1, 1:2, 1:4, 1:8, 1:16, 1:64, 1:128, and 1:256 are defined by TMRX. It is cleared when any type of reset occurs.

TMR1X, TMR2X and TMR3X (TMR1H/TMR1L, TMR2H/TMR2L, & TMR3H/TMR3L):

Timer X register; TMRX is increased until it matches with PRDX, and then is reset to 1 (default value).

PRDX (PRD1, PRD2 and PRD3):

PWM time period register.

Comparator X (Comparator 1 and Comparator 2):

Reset TMRX while a match occurs. The TMRXIF flag is set at the same time.

6.9.3 Programming the Related Registers

When defining TMRX, refer to the related registers of its operation as shown in the table below. It must be noted that the PWMX bits must be disabled if their related TMRXs are employed. That is, Bit 7 ~ Bit 5 of the PWMCON register must be set to '0'.

6.9.3.1 Related Control Registers of TMR1, TMR2, and TMR3

IOC90	TMRCON/IOC90	T3EN	T2EN	T3P2	T3P1	T3P0	T2P2	T2P1	T2P0

6.9.4 Timer Programming Process/Steps

1. Load PRDX with the Timer duration
2. Enable interrupt function by writing IOCF0, if required
3. Load a desired TMRX prescaler value to PWMCON and TMRCON and enable TMRX and disable PWMX

6.10 Comparator

The EM78P346N has one comparator comprising of two analog inputs and one output. The comparator can be utilized to wake up EM78P346N from sleep mode. The comparator circuit diagram is depicted in the figure below.

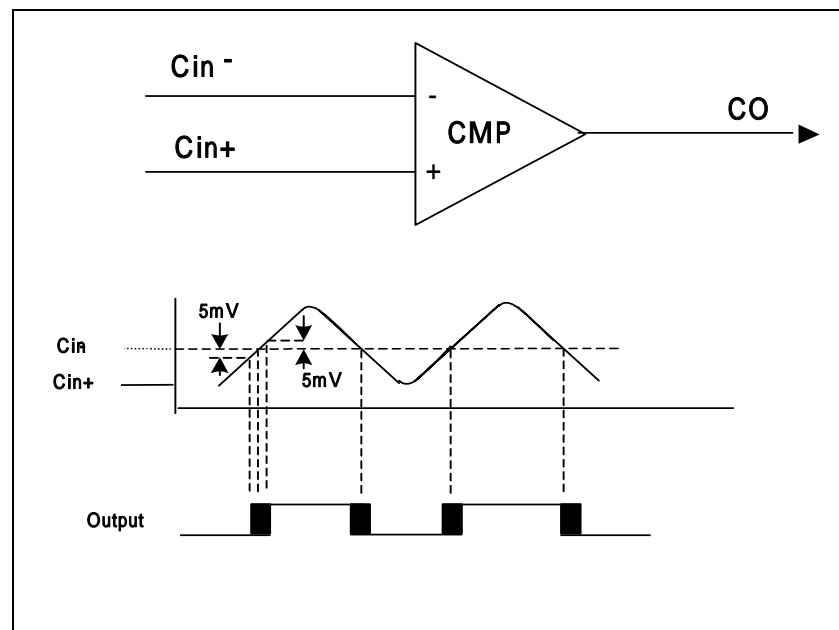

Figure 6-15 Comparator Circuit Diagram & Operating Mode

6.10.1 External Reference Signal

The analog signal that is presented at Cin⁻ compares to the signal at Cin⁺, and the digital output (CO) of the comparator is adjusted accordingly by taking the following notes into considerations:

NOTE

- The reference signal must be between Vss and Vdd.
- The reference voltage can be applied to either pin of the comparator.
- Threshold detector applications may be of the same reference.
- The comparator can operate from the same or different reference sources.

6.10.2 Comparator Outputs

- The compared result is stored in the CMPOUT of IOCA0.
- The comparator outputs are sent to CO (P60) by programming Bit 1, Bit 0 <COS1, COS0> of the IOCA0 register to <1, 0>. See Section 6.2.6, IOCA0 (CMPCON: Comparator Control Register) for Comparator/OP select bits function description.

NOTE

- The CO and ADE0 of the P60/ADE0/CO pins cannot be used at the same time.
- The P60/ADE0/CO pin priority is as follows:

P60/ADE0/CO Priority		
High	Medium	Low
CO	ADE0	P60

The following figure shows the Comparator Output block diagram.

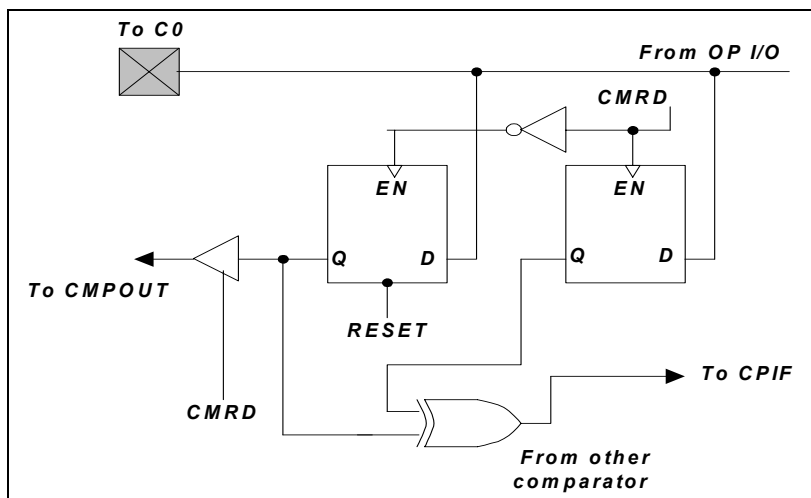

Figure 6-16 Comparator Output Configuration

6.10.3 Using Comparator as an Operation Amplifier

The comparator can be used as an operation amplifier if a feedback resistor is externally connected from the input to the output. In this case, the Schmitt trigger function can be disabled for power saving purposes, by setting Bit 1, Bit 0<COS1, COS0> of the IOCA0 register to <1, 1>. See Section 6.2.6, *IOCA0 (CMPCON: Comparator Control Register)* for Comparator/OP select bits function description.

6.10.4 Comparator Interrupt

- CMPIE (IOCF0.7) must be enabled for the “ENI” instruction to take effect.
- Interrupt is triggered whenever a change occurs on the comparator output pin.
- The actual change on the pin can be determined by reading the Bit CMPOUT, IOCA0<2>.
- CMPIF (RF.7), the comparator interrupt flag, can only be cleared by software.

6.10.5 Wake-up from Sleep Mode

- If enabled, the comparator remains active and the interrupt remains functional, even in Sleep mode.
- If a mismatch occurs, the interrupt will wake up the device from Sleep mode.
- The power consumption should be taken into consideration for the benefit of energy conservation.
- If the function is unemployed during Sleep mode, turn off the comparator before entering into sleep mode.

6.11 Oscillator

6.11.1 Oscillator Modes

The EM78P346N can be operated in four different oscillator modes, such as High Crystal oscillator mode (HXT), Low Crystal oscillator mode (LXT), External RC oscillator mode (ERC), and RC oscillator mode with Internal RC oscillator mode (IRC). One of the four modes can be selected by programming the OSC2, OCS1, and OSC0 in the Code Option register.

The Oscillator modes defined by OSC2, OCS1, and OSC0 are described below.

Oscillator Modes	OSC2	OSC1	OSC0
ERC ¹ (External RC oscillator mode); P54/OSCO functions as P54	0	0	0
ERC ¹ (External RC oscillator mode); P54/OSCO functions as OSCO	0	0	1
IRC ² (Internal RC oscillator mode); P54/OSCO functions as P54	0	1	0
IRC ² (Internal RC oscillator mode); P54/OSCO functions as OSCO	0	1	1
LXT1 (Frequency range of LXT1 mode is 1MHz ~ 100kHz)	1	0	0
HXT1 (Frequency range of HXT mode is 12MHz ~ 6MHz)	1	0	1
LXT2 (Frequency range of XT mode is 32kHz)	1	1	0
HXT2 (Frequency range of XT mode is 6MHz ~ 1MHz.) (default)	1	1	1

¹ In ERC mode, OSC1 is used as oscillator pin. OSCO/P54 is defined by Code Option Word 0 Bit 6 ~ Bit 4.

² In IRC mode, P55 is normal I/O pin. OSCO/P54 is defined by Code Option Word 0 Bit 6 ~ Bit 4.

The maximum operating frequency limit of crystal/resonator at different VDDs, are as follows:

Conditions	VDD	Max. Freq. (MHz)
Two clocks	2.1	4
	4.5	16

6.11.2 Crystal Oscillator/Ceramic Resonators (Crystal)

The EM78P346N can be driven by an external clock signal through the OSCO pin as illustrated below.

Figure 6-17 External Clock Input Circuit

In most applications, Pin OSCI and Pin OSCO can be connected with a crystal or ceramic resonator to generate oscillation. Figure 6-17 depicts such a circuit. The same applies to the HXT mode and the LXT mode.

Figure 6-18 Crystal/Resonator Circuit

The following table provides the recommended values for C1 and C2. Since each resonator has its own attribute, refer to the resonator specifications for appropriate values of C1 and C2. RS, a serial resistor, may be required for AT strip cut crystal or low frequency mode.

Oscillator Type	Frequency Mode	Frequency	C1 (pF)	C2 (pF)
Ceramic Resonators	HXT	455kHz	100~150	100~150
		2.0 MHz	20~40	20~40
		4.0 MHz	10~30	10~30
Crystal Oscillator	LXT	32.768kHz	25	15
		100kHz	25	25
		200kHz	25	25
	HXT	455kHz	20~40	20~150
		1.0MHz	15~30	15~30
		2.0MHz	15	15
		4.0MHz	15	15

6.11.3 External RC Oscillator Mode

For some applications that do not require precise timing calculation, the RC oscillator (Figure 6-19 at right) could offer an effective cost savings. Nevertheless, it should be noted that the frequency of the RC oscillator is influenced by the supply voltage, the values of the resistor (Rext), the capacitor (Cext), and even by the operation temperature. Moreover, the frequency also changes slightly from one chip to another due to the manufacturing process variation.

Figure 6-19 External RC Oscillator Mode Circuit

In order to maintain a stable system frequency, the values of the Cext should be no less than 20pF, and the value of Rext should not be greater than 1MΩ. If the frequency cannot be kept within this range, the frequency can be affected easily by noise, humidity, and leakage.

The smaller the Rext in the RC oscillator is, the faster its frequency will be. On the contrary, for very low Rext values, for instance, 1 KΩ, the oscillator will become unstable because the NMOS cannot correctly discharge the capacitance current.

Based on the above reasons, it must be kept in mind that all supply voltage, the operation temperature, the components of the RC oscillator, the package types, and the way the PCB is layout, have certain effect on the system frequency.

The RC Oscillator frequencies:

Cext	Rext	Average Fosc 5V, 25°C	Average Fosc 3V, 25°C
20 Pf	3.3k	3.5 MHz	3.0 MHz
	5.1k	2.4 MHz	2.2 MHz
	10k	1.27 MHz	1.24 MHz
	100k	140 kHz	143 kHz

6.11.4 Internal RC Oscillator Mode

The EM78P346N offers a versatile internal RC mode with default frequency value of 4MHz. Internal RC oscillator mode has other frequencies (16MHz, 1MHz, and 455kHz) that can be set by Code Option (Word 1), RCM1, and RCM0. The Table below describes the EM78P346N internal RC drift with voltage, temperature, and process variations.

6.12 Power-on Considerations

Any microcontroller is not warranted to start operating properly before the power supply stabilizes to a steady state. The EM78P346N has a built-in Power On Voltage Detector (POVD) with detection level range of 1.7V to 1.9V. The circuitry eliminates the extra external reset circuit. It will work well if V_{dd} rises quickly enough (50 ms or less). However, under critical applications, extra devices are still required to assist in solving power-on problems.

6.12.1 External Power-on Reset Circuit

The circuit shown in the following figure implements an external RC to produce a reset pulse. The pulse width (time constant) should be kept long enough to allow the V_{dd} to reach the minimum operating voltage.

This circuit is used when the power supply has a slow power rise time. Since the

current leakage from the /RESET pin is approximately $\pm 5\mu\text{A}$, it is recommended that R should not be greater than 40K. This way, the voltage at Pin /RESET is held below 0.2V. The diode (D) functions as a short circuit at power-down. The "C" capacitor is discharged rapidly and fully. R_{in}, the current-limited resistor, prevents high current discharge or ESD (electrostatic discharge) from flowing into Pin /RESET.

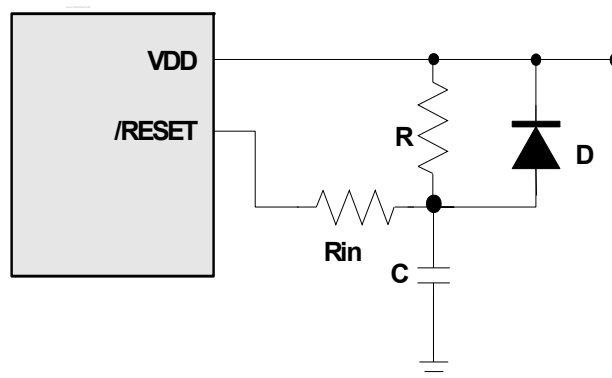

Figure 6-20 External Power-on Reset Circuit

6.12.2 Residual Voltage Protection

When the battery is replaced, device power (Vdd) is removed but residual voltage remains. The residual voltage may trip below Vdd minimum, but not to zero. This condition may cause a poor power-on reset. Figure 6-21 and Figure 6-22 show how to create a protection circuit against residual voltage.

6.14 Low Voltage Detector

During the power source unstable situation, such like external power noise interference or EMS test condition, it will cause the power vibrates fierce. At the time the V_{DD} is unsettled, the supply voltage may be below working voltage. When system supply voltage V_{DD} is below the working voltage, the IC kernel must keep all register status automatically.

6.14.2 Low Voltage Detector

LVD property setting at Registers RA, RE and detailed operation mode is as follows:

6.14.2.1 Bank 1 R6 (LVD Control Register)

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
-	LVDIF	/LVD	LVDIE	LVDWE	LVDEN	LVD1	LVD0

NOTE

- Bank 1 R6<4> register is both readable and writable
- Individual interrupt is enabled by setting its associated control bit in the Bank 1 R6<4> to "1."
- Global interrupt is enabled by the ENI instruction and is disabled by the DISI instruction. Refer to Figure 6-8 (Interrupt Input Circuit) under Section 6.6 (Interrupt).

Bit 6 (LVDIF): Low Voltage Detector interrupt flag

LVDIF is reset to "0" by software or hardware.

Bit 5 (/LVD): Low voltage Detector state. This is a read only bit. When the V_{DD} pin voltage is lower than the LVD voltage interrupt level (selected by LVD1 and LVD0), this bit will be cleared.

0 = Low voltage is detected.

1 = Low voltage is not detected or LVD function is disabled.

Bit 4 of Bank 1 R6: “1” means there’s interrupt request, and “0” means no interrupt occurs.

Bit 4 (LVDIE): Low voltage Detector interrupt enable bit.
0 = Disable Low voltage Detector interrupt.
1 = Enable Low voltage Detector interrupt.

When the detect low level voltage state is used to enter an interrupt vector or enter the next instruction, the LVDIE bit must be set to “Enable”.

Bit 3 (LVDWE): Low Voltage Detect wake-up enable bit
0 = Disable Low Voltage Detect wake-up
1 = Enable Low Voltage Detect wake-up

When the Low Voltage Detect is used to enter interrupt vector or to wake-up IC from sleep with Low Voltage Detect running, the LVDWE bit must be set to “Enable”.

Bit 2 (LVDEN): Low Voltage Detector enable bits.
0 = Low voltage detector disable
1 = Low voltage detector enable.

Bit 1~0 (LVD1:0): Low Voltage Detector level bits.

LVDEN	LVD1, LVD0	LVD Voltage Interrupt Level	/LVD
1	11	Vdd ≤ 2.3V	0
		Vdd > 2.3V	1
1	10	Vdd ≤ 3.3V	0
		Vdd > 3.3V	1
1	01	Vdd ≤ 4.0V	0
		Vdd > 4.0V	1
1	00	Vdd ≤ 4.5V	0
		Vdd > 4.5V	1
0	XX	NA	0

6.14.3 Programming Process

Follow these steps to obtain data from the LVD:

1. Write to the two bits (LVD1: LVD0) on the Bank 1-R6 (LVDCR) register to define the LVD level.
2. Set the LVDWE bit, if the wake-up function is employed.
3. Set the LVDIE bit, if the interrupt function is employed.
4. Write “ENI” instruction, if the interrupt function is employed.
5. Set LVDEN bit to 1
6. Write “SLEP” instruction or Polling /LVD bit.
7. Clear the interrupt flag bit (LVDIF) when Low Voltage is Detect occurs.

The internal LVD module uses the internal circuit, and when the code option is set to enable the LVD module, the current consumption will increase to about 5 μ A.

During sleep mode, the LVD module continues to operate. If the device voltage drops slowly and crosses the detect point, the LVDIF bit will be set and the device will wake up from Sleep mode. The LVD interrupt flag is still set as the prior status.

When system resets, the LVD flag will be cleared.

Figure 6-23 shows the LVD module to detect the external voltage situation.

When Vdd drops not below VLVD, LVDIF is kept at "0". When Vdd drops below VLVD, LVDIF is set to "1". If global ENI is enabled, LVDIF will be set to "1", the next instruction will branch to an interrupt vector. The LVD interrupt flag is cleared to "0" by software.

When Vdds drops below VRESET and it is less than 80 μ s, the system will keep all the register status and the system halts but oscillation is active. When Vdd drops below VRESET and it is more than 80 μ s, a system reset will occur. Refer to Section 6.5.1 for detailed RESET description.

Figure 6-23 LVD Waveform Situation

6.15 Instruction Set

Each instruction in the instruction set is a 13-bit word divided into an OP code and one or more operands. Normally, all instructions are executed within one single instruction cycle (one instruction consists of two oscillator time periods), unless the program counter is changed by instructions "MOV R2,A," "ADD R2,A," or by instructions of arithmetic or logic operation on R2 (e.g., "SUB R2,A," "BS(C) R2,6," "CLR R2," etc.). In this case, these instructions need one or two instruction cycles as determined by Code Option Register CYES bit.

In addition, the instruction set has the following features:

1. Every bit of any register can be set, cleared, or tested directly.
2. The I/O registers can be regarded as general registers. That is, the same instruction can operate on I/O registers.

The following symbols are used in the Instruction Set table:

Convention:

R = Register designator that specifies which one of the registers (including operation and general purpose registers) is to be utilized by the instruction.

Bits 6 and 7 in R4 determine the selected register bank.

b = Bit field designator that selects the value for the bit located in the register R and which affects the operation.

k = 8 or 10-bit constant or literal value

C.1 Address Trap Detect

An address trap detect is one of the MCU embedded fail-safe functions that detects MCU malfunction caused by noise or the like. Whenever the MCU attempts to fetch an instruction from a certain section of ROM, an internal recovery circuit is auto started. If a noise-caused address error is detected, the MCU will repeat execution of the program until the noise is eliminated. The MCU will then continue to execute the next program.
