Unbuffered DDR SO-DIMM

HYMD216M646C(L)6-D43/D4/J

DESCRIPTION

Hynix HYMD216M646C(L)6-D43/D4/J series is unbuffered 200-pin double data rate Synchronous DRAM Small Outline Dual In-Line Memory Modules (SO-DIMMs) which are organized as 16Mx64 high-speed memory arrays. Hynix HYMD216M646C(L)6-D43/D4/J series consists of four 16Mx16 DDR SDRAM in 400mil TSOP II packages on a 200pin glass-epoxy substrate. Hynix HYMD216M646C(L)6-D43/D4/J series provide a high performance 8-byte interface in 67.60mmX 31.75mm form factor of industry standard. It is suitable for easy interchange and addition.

Hynix HYMD216M646C(L)6-D43/D4/J series is designed for high speed of up to 200MHz and offers fully synchronous operations referenced to both rising and falling edges of differential clock inputs. While all addresses and control inputs are latched on the rising edges of the clock, Data, Data strobes and Write data masks inputs are sampled on both rising and falling edges of it. The data paths are internally pipelined and 2-bit prefetched to achieve very high bandwidth. All input and output voltage levels are compatible with SSTL_2. High speed frequencies, programmable latencies and burst lengths allow variety of device operation in high performance memory system.

Hynix HYMD216M646C(L)6-D43/D4/J series incorporates SPD(serial presence detect). Serial presence detect function is implemented via a serial 2,048-bit EEPROM. The first 128 bytes of serial PD data are programmed by Hynix to identify DIMM type, capacity and other the information of DIMM and the last 128 bytes are available to the customer.

0.5	0	0
0.4	+50	0
0.3	+100	0

- CK, /CK slew rates are $\geq 1.0\text{V/ns}$
- These parameters guarantee device timing, but they are not necessarily tested on each device, and they may be guaranteed by design or tester correlation.
- Data latched at both rising and falling edges of Data Strobes(LDQS/UDQS) : DQ, LDM/UDM.

8. Minimum of 200 cycles of stable input clocks after Self Refresh Exit command, where CKE is held high, is required to complete Self Refresh Exit and lock the internal DLL circuit of DDR SDRAM.
9. Min (tCL, tCH) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for tCL and tCH).
10. tHP = minimum half clock period for any given cycle and is defined by clock high or clock low (tCH, tCL). tQHS consists of tDQSQmax, the pulse width distortion of on-chip clock circuits, data pin to pin skew and output pattern effects and p-channel to n-channel variation of the output drivers.

11. This derating table is used to increase tDS/tDH in case where the input slew-rate is below 0.5V/ns.

Input Setup / Hold Slew-rate Derating Table.

Input Setup / Hold Slew-rate	Delta tDS	Delta tDH
V/ns	ps	ps
0.5	0	0
0.4	+75	+75
0.3	+150	+150

12. I/O Setup/Hold Plateau Derating. This derating table is used to increase tDS/tDH in case where the input level is flat below VREF +/-310mV for a duration of up to 2ns.

I/O Input Level	Delta tDS	Delta tDH
mV	ps	ps
+280	+50	+50

13. I/O Setup/Hold Delta Inverse Slew Rate Derating. This derating table is used to increase tDS/tDH in case where the DQ and DQS slew rates differ. The Delta Inverse Slew Rate is calculated as $(1/\text{SlewRate1}) - (1/\text{SlewRate2})$. For example, if slew rate 1=0.5V/ns and Slew Rate2 = 0.4V/n then the Delta Inverse Slew Rate = -0.5ns/V.

$(1/\text{SlewRate1}) - (1/\text{SlewRate2})$	Delta tDS	Delta tDH
ns/V	ps	ps
0	0	0
+/-0.25	+50	+50
+/- 0.5	+100	+100

14. DQS, DM and DQ input slew rate is specified to prevent double clocking of data and preserve setup and hold times. Signal transitions through the DC region must be monotonic.
15. $tDAL = (tDPL / tCK) + (tRP / tCK)$. For each of the terms above, if not already an integer, round to the next highest integer. tCK is equal to the actual system clock cycle time.
Example: For DDR400(D4) at CL=3 and tCK = 5 ns,
 $tDAL = (15.0 \text{ ns} / 5.0 \text{ ns}) + (18.0 \text{ ns} / 5.0 \text{ ns}) = (3.00) + (3.60)$
Round up each non-integer to the next highest integer: = (3) + (4), tDAL = 7 clock
16. For the parts which do not has internal RAS lockout circuit, Active to Read with Auto precharge delay should be $tRAS - BL/2 \times tCK$.
17. tHZ and tLZ transitions occur in the same access time windows as valid data transitions. These parameters are not referenced to a specific voltage level but specify when the device output is no longer driving (HZ), or begins driving (LZ).

Note :

1. LDM/UDM states are Don't Care. Refer to below Write Mask Truth Table.
2. OP Code(Operand Code) consists of A0~A12 and BA0~BA1 used for Mode Registering during Extended MRS or MRS.
Before entering Mode Register Set mode, all banks must be in a precharge state and MRS command can be issued after tRP period from Prechagre command.
3. If a Read with Autoprecharge command is detected by memory component in CK(n), then there will be no command presented to activated bank until CK(n+BL/2+tRP).
4. If a Write with Autoprecharge command is detected by memory component in CK(n), then there will be no command presented to activated bank until CK(n+BL/2+1+tdPL+tRP). Last Data-In to Prechagre delay(tdPL) which is also called Write Recovery Time (tWR) is needed to guarantee that the last data has been completely written.
5. If A10/AP is High when Row Precharge command being issued, BA0/BA1 are ignored and all banks are selected to be precharged.
