

# ZVS Full-Bridge PWM Controller with Adjustable Synchronous Rectifier Control

## ISL78223

The ISL78223 is a high-performance zero-voltage switching (ZVS) full-bridge PWM controller. It achieves ZVS operation by driving the upper bridge FETs at a fixed 50% duty cycle while the lower bridge FETs are trailing-edge modulated with adjustable resonant switching delays.

Adding to the ISL78223's feature set are average current monitoring and soft-start. The average current signal may be used for average current limiting, current sharing circuits and average current mode control. Additionally, the ISL78223 supports both voltage- and current-mode control.

The ISL78223 features complemented PWM outputs for synchronous rectifier (SR) control. The complemented outputs may be dynamically advanced or delayed relative to the PWM outputs using an external control voltage.

This advanced BiCMOS design features precision deadtime and resonant delay control, and an oscillator adjustable to 2MHz operating frequency. Additionally, Multi-Pulse Suppression ensures alternating output pulses at low duty cycles where pulse skipping may occur.

The ISL78223 is AEC - Q100 rated. The ISL78223 is rated for the automotive temperature range (-40°C to +105°C).

## Features

- Adjustable resonant delay for ZVS operation
- Synchronous rectifier control outputs with adjustable delay/advance
- Voltage- or current-mode control
- 3% current limit threshold
- Adjustable average current limit
- Adjustable deadtime control
- 175μA start-up current
- Supply UVLO
- Adjustable oscillator frequency up to 2MHz
- Internal over-temperature protection
- Buffered oscillator sawtooth output
- Fast current sense to output delay
- Adjustable cycle-by-cycle peak current limit
- 70ns leading edge blanking
- Multi-pulse suppression
- AEC - Q100 qualified
- Pb-free (RoHS compliant)

## Applications

- ZVS full-bridge converters
- Telecom and datacom power
- Wireless base station power
- File server power
- Industrial power systems

## Pin Configuration

## Pin Descriptions

PIN NUMBER	SYMBOL	DESCRIPTION
1	VREF	The 5.00V reference voltage output having 3% tolerance over line, load and operating temperature. Bypass to GND with a 0.1μF to 2.2μF low ESR capacitor.
2	VERR	The control voltage input to the inverting input of the PWM comparator. The output of an external error amplifier (EA) is applied to this input, either directly or through an opto-coupler, for closed loop regulation. VERR has a nominal 1mA pull-up current source. When VERR is driven by an opto-coupler or other current source device, a pull-up resistor from VREF is required to linearize the gain. Generally, a pull-up resistor on the order of 5kΩ is acceptable.
3	CTBUF	CTBUF is the buffered output of the sawtooth oscillator waveform present on CT and is capable of sourcing 2mA. It is offset from ground by 0.40V and has a nominal valley-to-peak gain of 2. It may be used for slope compensation.
4	RTD	This is the oscillator timing capacitor discharge current control pin. The current flowing in a resistor connected between this pin and GND determines the magnitude of the current that discharges CT. The CT discharge current is nominally 20x the resistor current. The PWM deadtime is determined by the timing capacitor discharge duration. The voltage at RTD is nominally 2.00V.
5	RESDEL	Sets the resonant delay period between the toggle of the upper FETs and the turn on of either of the lower FETs. The voltage applied to RESDEL determines when the upper FETs switch relative to a lower FET turning on. Varying the control voltage from 0 to 2.00V increases the resonant delay duration from 0 to 100% of the deadtime. The control voltage divided by 2 represents the percent of the deadtime equal to the resonant delay. In practice the maximum resonant delay must be set lower than 2.00V to ensure that the lower FETs, at maximum duty cycle, are OFF prior to the switching of the upper FETs.
6	CT	The oscillator timing capacitor is connected between this pin and GND. It is charged through an internal 200μA current source and discharged with a user adjustable current source controlled by RTD
7	FB	FB is the inverting inputs to the error amplifier (EA). The amplifier may be used as the error amplifier for voltage feedback or used as the average current limit amplifier (IEA). If the amplifier is not used, FB should be grounded.
8	RAMP	This is the input for the sawtooth waveform for the PWM comparator. The RAMP pin is shorted to GND at the termination of the PWM signal. A sawtooth voltage waveform is required at this input. For current-mode control this pin is connected to CS and the current loop feedback signal is applied to both inputs. For voltage-mode control, the oscillator sawtooth waveform may be buffered and used to generate an appropriate signal, RAMP may be connected to the input voltage through a RC network for voltage feed forward control, or RAMP may be connected to VREF through a RC network to produce the desired sawtooth waveform.
9	CS	This is the input to the overcurrent comparator. The overcurrent comparator threshold is set at 1.00V nominal. The CS pin is shorted to GND at the termination of either PWM output. Depending on the current sensing source impedance, a series input resistor may be required due to the delay between the internal clock and the external power switch. This delay may result in CS being discharged prior to the power switching device being turned off.

## Pin Descriptions (Continued)

PIN NUMBER	SYMBOL	DESCRIPTION
10	IOUT	Output of the 4X buffer amplifier of the sample and hold circuitry that captures and averages the CS signal.
11	GND	Signal and power ground connections for this device. Due to high peak currents and high frequency operation, a low impedance layout is necessary. Ground planes and short traces are highly recommended.
13, 12	OUTLLN, OUTLRN	These outputs are the complements of the PWM (lower) bridge FETs. OUTLLN is the complement of OUTLL and OUTLRN is the complement of OUTLR. These outputs are suitable for control of synchronous rectifiers. The phase relationship between each output and its complement is controlled by the voltage applied to VADJ.
15, 14	OUTUL, OUTUR	These outputs control the upper bridge FETs and operate at a fixed 50% duty cycle in alternate sequence. OUTUL controls the upper left FET and OUTUR controls the upper right FET. The left and right designation may be switched as long as they are switched in conjunction with the lower FET outputs, OUTLL and OUTLR.
17, 16	OUTLL, OUTLR	These outputs control the lower bridge FETs, are pulse width modulated, and operate in alternate sequence. OUTLL controls the lower left FET and OUTLR controls the lower right FET. The left and right designation may be switched as long as they are switched in conjunction with the upper FET outputs, OUTUL and OUTUR.
18	VDD	V <sub>DD</sub> is the power connection for the IC. To optimize noise immunity, bypass V <sub>DD</sub> to GND with a ceramic capacitor as close to the V <sub>DD</sub> and GND pins as possible. VDD is monitored for supply voltage undervoltage lock-out (UVLO). The start and stop thresholds track each other resulting in relatively constant hysteresis.
19	VADJ	A 0V to 5V control voltage applied to this input sets the relative delay or advance between OUTLL/OUTLR and OUTLLN/OUTLRN. The phase relationship between OUTUL/OUTUR and OUTLL/OUTLR is maintained regardless of the phase adjustment between OUTLL/OUTLR and OUTLLN/OUTLRN. The range of phase delay/advance is either zero or 40 to 300ns with the phase differential increasing as the voltage deviation from 2.5V increases. The relationship between the control voltage and phase differential is non-linear. The gain ( $\Delta t/\Delta V$ ) is low for control voltages near 2.5V and rapidly increases as the voltage approaches the extremes of the control range. This behavior provides the user increased accuracy when selecting a shorter delay/advance duration. When the PWM outputs are delayed relative to the SR outputs (VADJ < 2.425V), the delay time should not exceed 90% of the deadtime as determined by RTD and CT.
20	SS	Connect the soft-start timing capacitor between this pin and GND to control the duration of soft-start. The value of the capacitor and the internal current source determine the rate of increase of the duty cycle during start-up. SS may also be used to inhibit the outputs by grounding through a small transistor in an open collector/drain configuration.

## Ordering Information

PART NUMBER (Notes 1, 2, 3)	PART MARKING	TEMP. RANGE (°C)	PACKAGE (Pb-free)	PKG. DWG. #
ISL78223AAZ	78223 AAZ	-40 to +105	20 Ld QSOP	M20.15

1. Add "-T\*" suffix for tape and reel. Please refer to [TB347](#) for details on reel specifications.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), please see device information page for [ISL78223](#). For more information on MSL, please see tech brief [TB363](#).

## Absolute Maximum Ratings

Supply Voltage, $V_{DD}$	GND - 0.3V to +22.0V
OUTxxx	GND - 0.3V to $V_{DD}$
Signal Pins	GND - 0.3V to $V_{REF} + 0.3V$
$V_{REF}$	GND - 0.3V to 6.0V
Peak GATE Current	0.1A
ESD Rating	
Human Body Model (Tested per JESD22-A114F)	2kV
Machine Model (Tested per JESD22-A115C)	200V
Charged Device Model (Tested per JESD22-C101E)	1kV
Latchup Rating (Tested per JESD78B; Class II, Level A)	100mA

## Thermal Information

Thermal Resistance (Typical)	$\theta_{JA}$ ( $^{\circ}\text{C}/\text{W}$ )	$\theta_{JC}$ ( $^{\circ}\text{C}/\text{W}$ )
20 Lead QSOP (Notes 4, 5)	88	48
Maximum Junction Temperature	-55 $^{\circ}\text{C}$ to +150 $^{\circ}\text{C}$	
Maximum Storage Temperature Range	-65 $^{\circ}\text{C}$ to +150 $^{\circ}\text{C}$	
Pb-Free Reflow Profile	see link below <a href="http://www.intersil.com/pbfree/Pb-FreeReflow.asp">http://www.intersil.com/pbfree/Pb-FreeReflow.asp</a>	

## Operating Conditions

Temperature Range	-40 $^{\circ}\text{C}$ to +105 $^{\circ}\text{C}$
Supply Voltage Range (Typical)	9VDC to 16VDC

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

### NOTES:

- $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air. See Tech Brief [TB379](#) for details.
- For  $\theta_{JC}$ , the "case temp" location is taken at the package top center.
- All voltages are with respect to GND.

**Electrical Specifications** Recommended operating conditions unless otherwise noted. Refer to "Functional Block Diagram" on page 2 and "Typical Application" schematics beginning on page 3. 9V <  $V_{DD}$  < 20V, RTD = 10.0k $\Omega$ , CT = 470pF,  $T_A$  = -40 $^{\circ}\text{C}$  to +105 $^{\circ}\text{C}$ , Typical values are at  $T_A$  = +25 $^{\circ}\text{C}$ . **Boldface limits apply over the operating temperature range, -40 $^{\circ}\text{C}$  to +105 $^{\circ}\text{C}$ .**

**NOTES:**

- Limits established by characterization and are not production tested.
- This is the maximum duty cycle achievable using the specified values of  $RTD$  and  $CT$ . Larger or smaller maximum duty cycles may be obtained using other values for these components. See Equations 1 through 3.
- Adjust  $V_{DD}$  below the UVLO stop threshold prior to setting at 7V.
- When OUTLx is delayed relative to OUTLxN ( $V_{ADJ} < 2.425V$ ), the delay duration as set by  $V_{ADJ}$  should not exceed 90% of the  $CT$  discharge time (deadtime) as determined by  $CT$  and  $RTD$ .
- Parameters with MIN and/or MAX limits are 100% tested at  $+25^\circ C$ , unless otherwise specified. Temperature limits established by characterization and are not production tested.

## Functional Description

### Features

The ISL78223 PWM is an excellent choice for low cost ZVS full-bridge applications requiring adjustable synchronous rectifier drive. With its many protection and control features, a highly flexible design with minimal external components is possible. Among its many features are a very accurate overcurrent limit threshold, thermal protection, a buffered sawtooth oscillator output suitable for slope compensation, synchronous rectifier outputs with variable delay/advance timing, and adjustable frequency.

### Oscillator

The ISL78223 has an oscillator with a programmable frequency range to 2MHz, which can be programmed with a resistor and capacitor.

The switching period is the sum of the timing capacitor charge and discharge durations. The charge duration is determined by CT and a fixed 200μA internal current source. The discharge duration is determined by RTD and CT.

$$T_C \approx 11.5 \cdot 10^3 \cdot CT \quad S \quad (EQ. 1)$$

$$T_D \approx (0.06 \cdot RTD \cdot CT) + 50 \cdot 10^{-9} \quad S \quad (EQ. 2)$$

$$T_{SW} = T_C + T_D = \frac{1}{F_{SW}} \quad S \quad (EQ. 3)$$

where  $T_C$  and  $T_D$  are the charge and discharge times, respectively, CT is the timing capacitor in Farads, RTD is the discharge programming resistance in ohms,  $T_{SW}$  is the oscillator period, and  $F_{SW}$  is the oscillator frequency. One output switching cycle requires two oscillator cycles. The actual times will be slightly longer than calculated due to internal propagation delays of approximately 10ns/transition. This delay adds directly to the switching duration, but also causes overshoot of the timing capacitor peak and valley voltage thresholds, effectively increasing the peak-to-peak voltage on the timing capacitor. Additionally, if very small discharge currents are used, there will be increased error due to the input impedance at the CT pin. The maximum recommended current through RTD is 1mA, which produces a CT discharge current of 20mA.

The maximum duty cycle, D, and percent deadtime, DT, can be calculated from:

$$D = \frac{T_C}{T_{SW}} \quad (EQ. 4)$$

$$DT = 1 - D \quad (EQ. 5)$$

### Overcurrent Operation

Two overcurrent protection mechanisms are available to the power supply designer. The first method is cycle-by-cycle peak overcurrent protection which provides fast response. The cycle-by-cycle peak current limit results in pulse-by-pulse duty cycle reduction when the current feedback signal exceeds 1.0V. When the peak current exceeds the threshold, the active output pulse is immediately terminated. This results in a decrease in output voltage as the load current increases beyond the current limit

threshold. The ISL78223 operates continuously in an overcurrent condition without shutdown.

The second method is a slower, averaging method which produces constant or “brick-wall” current limit behavior. If voltage-mode control is used, the average overcurrent protection also maintains flux balance in the transformer by maintaining duty cycle symmetry between half-cycles. If voltage-mode control is used in a bridge topology, it should be noted that peak current limit results in inherently unstable operation. The DC blocking capacitors used in voltage-mode bridge topologies become unbalanced, as does the flux in the transformer core. Average current limit will prevent the instability and allow continuous operation in current limit provided the control loop is designed with adequate bandwidth.

The propagation delay from CS exceeding the current limit threshold to the termination of the output pulse is increased by the leading edge blanking (LEB) interval. The effective delay is the sum of the two delays and is nominally 105ns.

The current sense signal applied to the CS pin connects to the peak current comparator and a sample and hold averaging circuit. After a 70ns leading edge blanking (LEB) delay, the current sense signal is actively sampled during the on time, the average current for the cycle is determined, and the result is amplified by 4x and output on the  $I_{OUT}$  pin. If an RC filter is placed on the CS input, its time constant should not exceed ~50ns or significant error may be introduced on  $I_{OUT}$ .

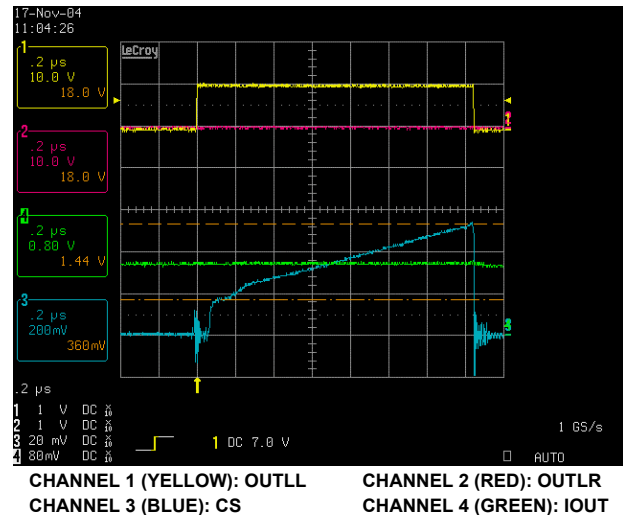

FIGURE 7. CS INPUT vs  $I_{OUT}$

Figure 7 shows the relationship between the CS signal and  $I_{OUT}$  under steady state conditions.  $I_{OUT}$  is 4x the average of CS. Figure 8 shows the dynamic behavior of the current averaging circuitry when CS is modulated by an external sine wave. Notice  $I_{OUT}$  is updated by the sample and hold circuitry at the termination of the active output pulse.

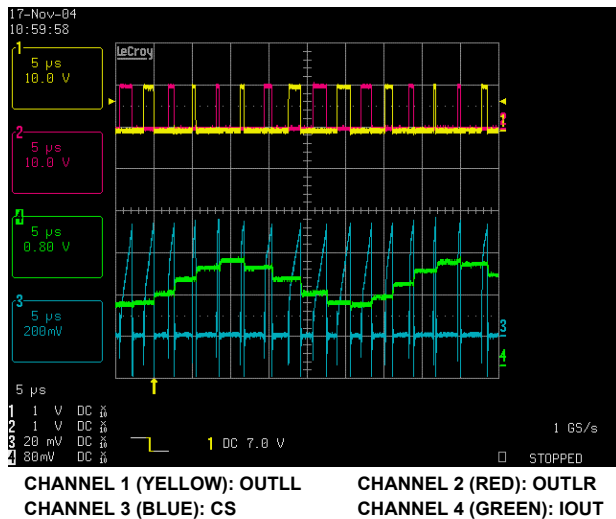

FIGURE 8. DYNAMIC BEHAVIOR OF CS vs IOUT

The average current signal on IOUT remains accurate provided the output inductor current remains continuous (CCM operation). Once the inductor current becomes discontinuous (DCM operation), IOUT represents 1/2 the peak inductor current rather than the average current. This occurs because the sample and hold circuitry is active only during the on time of the switching cycle. It is unable to detect when the inductor current reaches zero during the off time.

If average overcurrent limit is desired, IOUT may be used with the error amplifier of the ISL78223. Typically IOUT is divided down and filtered as required to achieve the desired amplitude. The resulting signal is input to the current error amplifier (IEA). The IEA is similar to the voltage EA found in most PWM controllers, except it cannot source current. Instead, VERR has a separate internal 1mA pull-up current source.

Configure the IEA as an integrating (Type I) amplifier using the internal 0.6V reference. The voltage applied at FB is integrated against the 0.6V reference. The resulting signal, VERR, is applied to the PWM comparator where it is compared to the sawtooth voltage on RAMP. If FB is less than 0.6V, the IEA will be open loop (can't source current), VERR will be at a level determined by the voltage loop, and the duty cycle is unaffected. As the output load increases, IOUT will increase, and the voltage applied to FB will increase until it reaches 0.6V. At this point the IEA will reduce VERR as required to maintain the output current at the level that corresponds to the 0.6V reference. When the output current again drops below the average current limit threshold, the IEA returns to an open loop condition, and the duty cycle is again controlled by the voltage loop.

The average current control loop behaves much the same as the voltage control loop found in typical power supplies except it regulates current rather than voltage.

The EA available on the ISL78223 may also be used as the voltage EA for the voltage feedback control loop rather than the current EA as described above. An external op-amp may be used as either the current or voltage EA providing the circuit is not allowed to source current into VERR. The external EA must only sink current, which may be accomplished by adding a diode in series with its output.

The 4x gain of the sample and hold buffer allows a range of 150 - 1000mV peak on the CS signal, depending on the resistor divider placed on IOUT. The overall bandwidth of the average current loop is determined by the integrating current EA compensation and the divider on IOUT.

FIGURE 9. AVERAGE OVERCURRENT IMPLEMENTATION

The current EA cross-over frequency, assuming  $R6 \gg (R4 \parallel R5)$ , is:

$$f_{CO} = \frac{1}{2\pi \cdot R6 \cdot C10} \quad \text{Hz} \quad (\text{EQ. 6})$$

where  $f_{CO}$  is the cross-over frequency. A capacitor in parallel with R4 may be used to provide a double-pole roll-off.

The average current loop bandwidth is normally set to be much less than the switching frequency, typically less than 5kHz and often as slow as a few hundred hertz or less. This is especially useful if the application experiences large surges. The average current loop can be set to the steady state overcurrent threshold and have a time response that is longer than the required transient. The peak current limit can be set higher than the expected transient so that it does not interfere with the transient, but still protects for short-term larger faults. In essence a 2-stage overcurrent response is possible.

The peak overcurrent behavior is similar to most other PWM controllers. If the peak current exceeds 1.0V, the active output pulse is terminated immediately.

If voltage-mode control is used in a bridge topology, it should be noted that peak current limit results in inherently unstable operation. DC blocking capacitors used in voltage-mode bridge topologies become unbalanced, as does the flux in the transformer core. The average overcurrent circuitry prevents this behavior by maintaining symmetric duty cycles for each half-cycle. If the average current limit circuitry is not used, a latching overcurrent shutdown method using external components is recommended.

The CS to output propagation delay is increased by the leading edge blanking (LEB) interval. The effective delay is the sum of the two delays and is 130ns maximum.

## Voltage Feed Forward Operation

Voltage feed forward is a technique used to regulate the output voltage for changes in input voltage without the intervention of the control loop. Voltage feed forward is implemented in voltage-mode control loops, but is redundant and unnecessary in peak current-mode control loops.

Voltage feed forward operates by modulating the sawtooth ramp in direct proportion to the input voltage. Figure 10 demonstrates the concept.

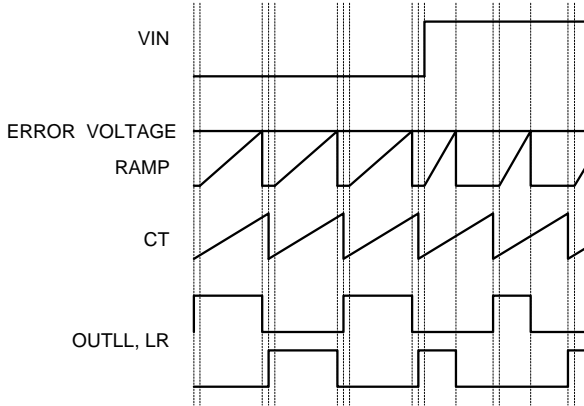

FIGURE 10. VOLTAGE FEED FORWARD BEHAVIOR

Input voltage feed forward may be implemented using the RAMP input. An RC network connected between the input voltage and ground, as shown in Figure 11, generates a voltage ramp whose charging rate varies with the amplitude of the source voltage. At the termination of the active output pulse, RAMP is discharged to ground so that a repetitive sawtooth waveform is created. The RAMP waveform is compared to the VERR voltage to determine duty cycle. The selection of the RC components depends upon the desired input voltage operating range and the frequency of the oscillator. In typical applications, the RC components are selected so that the ramp amplitude reaches 1.0V at minimum input voltage within the duration of one half-cycle.

FIGURE 11. VOLTAGE FEED FORWARD CONTROL

The charging time of the ramp capacitor is:

$$t = -R3 \cdot C7 \cdot \ln\left(1 - \frac{V_{RAMP(PEAK)}}{V_{IN(MIN)}}\right) \quad S \quad (EQ. 7)$$

For optimum performance, the maximum value of the capacitor should be limited to 10nF. The maximum DC current through the resistor should be limited to 2mA maximum. For example, if the oscillator frequency is 400kHz, the minimum input voltage is 300V, and a 4.7nF ramp capacitor is selected, the value of the resistor can be determined by rearranging Equation 7.

$$R3 = \frac{-t}{C7 \cdot \ln\left(1 - \frac{V_{RAMP(PEAK)}}{V_{IN(MIN)}}\right)} = \frac{-2.5 \cdot 10^{-6}}{4.7 \cdot 10^{-9} \cdot \ln\left(1 - \frac{1}{300}\right)} = 159 \quad k\Omega \quad (EQ. 8)$$

where t is equal to the oscillator period minus the deadtime. If the deadtime is short relative to the oscillator period, it can be ignored for this calculation.

If feed forward operation is not desired, the RC network may be connected to  $V_{REF}$  rather than the input voltage. Alternatively, a resistor divider from CTBUF may be used as the sawtooth signal. Regardless, a sawtooth waveform must be generated on RAMP as it is required for proper PWM operation.

## Gate Drive

The ISL78223 outputs are capable of sourcing and sinking 10mA (at rated  $V_{OH}$ ,  $V_{OL}$ ) and are intended to be used in conjunction with integrated FET drivers or discrete bipolar totem pole drivers. The typical on resistance of the outputs is 50Ω.

## Slope Compensation

Peak current-mode control requires slope compensation to improve noise immunity, particularly at lighter loads, and to prevent current loop instability, particularly for duty cycles greater than 50%. Slope compensation may be accomplished by summing an external ramp with the current feedback signal or by subtracting the external ramp from the voltage feedback error signal. Adding the external ramp to the current feedback signal is the more popular method.

From the small signal current-mode model [1] it can be shown that the naturally-sampled modulator gain,  $F_m$ , without slope compensation, is:

$$F_m = \frac{1}{S_n T_{sw}} \quad (EQ. 9)$$

where  $S_n$  is the slope of the sawtooth signal and  $T_{sw}$  is the duration of the half-cycle. When an external ramp is added, the modulator gain becomes:

$$F_m = \frac{1}{(S_n + S_e) T_{sw}} = \frac{1}{m_c S_n T_{sw}} \quad (EQ. 10)$$

where  $S_e$  is slope of the external ramp and

$$m_c = 1 + \frac{S_e}{S_n} \quad (EQ. 11)$$

The criteria for determining the correct amount of external ramp can be determined by appropriately setting the damping factor of the double-pole located at half the oscillator frequency. The double-pole will be critically damped if the Q-factor is set to 1, and over-damped for  $Q > 1$ , and under-damped for  $Q < 1$ . An under-damped condition can result in current loop instability.

$$Q = \frac{1}{\pi(m_c(1-D) - 0.5)} \quad (\text{EQ. 12})$$

where D is the percent of on time during a half cycle. Setting  $Q = 1$  and solving for  $S_e$  yields:

$$S_e = S_n \left( \left( \frac{1}{\pi} + 0.5 \right) \frac{1}{1-D} - 1 \right) \quad (\text{EQ. 13})$$

Since  $S_n$  and  $S_e$  are the on time slopes of the current ramp and the external ramp, respectively, they can be multiplied by  $T_{ON}$  to obtain the voltage change that occurs during  $T_{ON}$ .

$$V_e = V_n \left( \left( \frac{1}{\pi} + 0.5 \right) \frac{1}{1-D} - 1 \right) \quad (\text{EQ. 14})$$

where  $V_n$  is the change in the current feedback signal during the on time and  $V_e$  is the voltage that must be added by the external ramp.

$V_n$  can be solved for in terms of input voltage, current transducer components, and output inductance yielding:

$$V_e = \frac{T_{SW} \cdot V_O \cdot R_{CS}}{N_{CT} \cdot L_O} \cdot \frac{N_S}{N_P} \left( \frac{1}{\pi} + D - 0.5 \right) \quad V \quad (\text{EQ. 15})$$

where  $R_{CS}$  is the current sense burden resistor,  $N_{CT}$  is the current transformer turns ratio,  $L_O$  is the output inductance,  $V_O$  is the output voltage, and  $N_S$  and  $N_P$  are the secondary and primary turns, respectively.

The inductor current, when reflected through the isolation transformer and the current sense transformer to obtain the current feedback signal at the sense resistor yields:

$$V_{CS} = \frac{N_S \cdot R_{CS}}{N_P \cdot N_{CT}} \left( I_O + \frac{D \cdot T_{SW}}{2L_O} \left( V_{IN} \cdot \frac{N_S}{N_P} - V_O \right) \right) \quad V \quad (\text{EQ. 16})$$

where  $V_{CS}$  is the voltage across the current sense resistor and  $I_O$  is the output current at current limit.

Since the peak current limit threshold is 1.00V, the total current feedback signal plus the external ramp voltage must sum to this value.

$$V_e + V_{CS} = 1 \quad (\text{EQ. 17})$$

Substituting Equations 15 and 16 into Equation 17 and solving for  $R_{CS}$  yields:

$$R_{CS} = \frac{N_P \cdot N_{CT}}{N_S} \cdot \frac{1}{I_O + \frac{V_O}{L_O} T_{SW} \left( \frac{1}{\pi} + \frac{D}{2} \right)} \quad \Omega \quad (\text{EQ. 18})$$

For simplicity, idealized components have been used for this discussion, but the effect of magnetizing inductance must be considered when determining the amount of external ramp to add. Magnetizing inductance provides a degree of slope

compensation to the current feedback signal and reduces the amount of external ramp required. The magnetizing inductance adds primary current in excess of what is reflected from the inductor current in the secondary.

$$\Delta I_P = \frac{V_{IN} \cdot DT_{SW}}{L_m} \quad A \quad (\text{EQ. 19})$$

where  $V_{IN}$  is the input voltage that corresponds to the duty cycle D and  $L_m$  is the primary magnetizing inductance. The effect of the magnetizing current at the current sense resistor,  $R_{CS}$ , is:

$$\Delta V_{CS} = \frac{\Delta I_P \cdot R_{CS}}{N_{CT}} \quad V \quad (\text{EQ. 20})$$

If  $\Delta V_{CS}$  is greater than or equal to  $V_e$ , then no additional slope compensation is needed and  $R_{CS}$  becomes:

$$R_{CS} = \frac{N_{CT}}{\frac{N_S}{N_P} \cdot \left( I_O + \frac{DT_{SW}}{2L_O} \cdot \left( V_{IN} \cdot \frac{N_S}{N_P} - V_O \right) \right) + \frac{V_{IN} \cdot DT_{SW}}{L_m}} \quad (\text{EQ. 21})$$

If  $\Delta V_{CS}$  is less than  $V_e$ , then Equation 16 is still valid for the value of  $R_{CS}$ , but the amount of slope compensation added by the external ramp must be reduced by  $\Delta V_{CS}$ .

Adding slope compensation may be accomplished in the ISL78223 using the CTBUF signal. CTBUF is an amplified representation of the sawtooth signal that appears on the CT pin. It is offset from ground by 0.4V and is 2x the peak-to-peak amplitude of CT (0.4V to 4.4V). A typical application sums this signal with the current sense feedback and applies the result to the CS pin as shown in Figure 12.

FIGURE 12. ADDING SLOPE COMPENSATION

Assuming the designer has selected values for the RC filter placed on the CS pin, the value of  $R_9$  required to add the appropriate external ramp can be found by superposition.

$$V_e - \Delta V_{CS} = \frac{(D(V_{CTBUF} - 0.4) + 0.4) \cdot R_6}{R_6 + R_9} \quad V \quad (\text{EQ. 22})$$

Rearranging to solve for R9 yields:

$$R9 = \frac{(D(V_{CTBUF} - 0.4) - V_e + \Delta V_{CS} + 0.4) \cdot R6}{V_e - \Delta V_{CS}} \quad \Omega \quad (EQ. 23)$$

The value of  $R_{CS}$  determined in Equation 18 or 21 must be rescaled so that the current sense signal presented at the CS pin is that predicted by Equation 16. The divider created by R6 and R9 makes this necessary.

$$R'_{CS} = \frac{R6 + R9}{R9} \cdot R_{CS} \quad (EQ. 24)$$

Example:

$$V_{IN} = 280V$$

$$V_O = 12V$$

$$L_O = 2.0\mu H$$

$$N_p/N_s = 20$$

$$L_m = 2mH$$

$$I_O = 55A$$

$$\text{Oscillator Frequency, } F_{sw} = 400kHz$$

$$\text{Duty Cycle, } D = 85.7\%$$

$$N_{CT} = 50$$

$$R6 = 499\Omega$$

Solve for the current sense resistor,  $R_{CS}$ , using Equation 18.

$$R_{CS} = 15.1\Omega$$

Determine the amount of voltage,  $V_e$ , that must be added to the current feedback signal using Equation 15.

$$V_e = 153mV$$

Next, determine the effect of the magnetizing current from Equation 20.

$$\Delta V_{CS} = 91mV$$

Using Equation 23, solve for the summing resistor, R9, from CTBUF to CS.

$$R9 = 30.1k\Omega$$

Determine the new value of  $R_{CS}$ ,  $R'_{CS}$ , using Equation 24.

$$R'_{CS} = 15.4\Omega$$

The above discussion determines the minimum external ramp that is required. Additional slope compensation may be considered for design margin.

If the application requires deadtime less than about 500ns, the CTBUF signal may not perform adequately for slope compensation. CTBUF lags the CT sawtooth waveform by 300ns to 400ns. This behavior results in a non-zero value of CTBUF when the next half-cycle begins when the deadtime is short.

Under these situations, slope compensation may be added by externally buffering the CT signal as shown in Figure 13.

FIGURE 13. ADDING SLOPE COMPENSATION USING CT

Using CT to provide slope compensation instead of CTBUF requires the same calculations, except that Equations 22 and 23 require modification. Equation 22 becomes:

$$V_e - \Delta V_{CS} = \frac{2D \cdot R6}{R6 + R9} \quad V \quad (EQ. 25)$$

and Equation 23 becomes:

$$R9 = \frac{(2D - V_e + \Delta V_{CS}) \cdot R6}{V_e - \Delta V_{CS}} \quad \Omega \quad (EQ. 26)$$

The buffer transistor used to create the external ramp from CT should have a sufficiently high gain (>200) so as to minimize the required base current. Whatever base current is required reduces the charging current into CT and will reduce the oscillator frequency.

## ZVS Full-Bridge Operation

The ISL78223 is a full-bridge zero-voltage switching (ZVS) PWM controller that behaves much like a traditional hard-switched topology controller. Rather than drive the diagonal bridge switches simultaneously, the upper switches (OUTUL, OUTUR) are driven at a fixed 50% duty cycle and the lower switches (OUTLL, OUTLR) are pulse width modulated on the trailing edge.

The schematic diagram illustrates a full-bridge inverter circuit. The input is a split-phase AC source with terminals labeled VIN+ and VIN-. The inverter consists of four power MOSFETs: UL (top-left), UR (top-right), LL (bottom-left), and LR (bottom-right). Each MOSFET has an anti-parallel capacitor connected to its gate and drain. The drains of UL and UR are connected to the primary winding of a transformer. The sources of LL and LR are connected to the secondary winding of the transformer. The primary winding has an inductor L in series with the UR drain. The secondary winding is connected to a full-bridge rectifier consisting of two diodes, D1 and D2. The output of the rectifier is connected to a load consisting of an inductor and a capacitor in parallel. The output terminals are labeled VOUT+ and RTN.

In Figure 15, the power semiconductor switches have been replaced by ideal switch elements with parallel diodes and capacitance, the output rectifiers are ideal, and the transformer leakage inductance has been included as a discrete element. The parasitic capacitance has been lumped together as switch capacitance, but represents all parasitic capacitance in the circuit including winding capacitance. Each switch is designated by its position, upper left (UL), upper right (UR), lower left (LL), and lower right (LR). The beginning of the cycle, shown in Figure 16, is arbitrarily set as having switches UL and LR on and UR and LL off. The direction of the primary and secondary currents are indicated by  $I_P$  and  $I_S$ , respectively.

alternate path. The current flows into the parasitic switch capacitance of LR and UR which charges the node to  $V_{IN}$  and then forward biases the body diode of upper switch UR.

The current flow from the previous power transfer cycle tends to be maintained during the free-wheeling period because the transformer primary winding is essentially shorted. Diode D1 may conduct very little or none of the free-wheeling current, depending on circuit parasitics. This behavior is quite different than what occurs in a conventional hard-switched full-bridge topology where the free-wheeling current splits nearly evenly between the output diodes, and flows not at all in the primary.

During the period when CT discharges, also referred to as the deadtime, the upper switches toggle. Switch UL turns off and switch UR turns on. The actual timing of the upper switch toggle is dependent on RESEDL which sets the resonant delay. The voltage applied to RESEDL determines how far in advance the toggle occurs prior to a lower switch turning on. The ZVS transition occurs after the upper switches toggle and before the diagonal lower switch turns on. The required resonant delay is  $1/4$  of the period of the LC resonant frequency of the circuit formed by the leakage inductance and the parasitic capacitance. The resonant transition may be estimated from Equation 27.

where  $\tau$  is the resonant transition time,  $L_L$  is the leakage inductance,  $C_P$  is the parasitic capacitance, and  $R$  is the equivalent resistance in series with  $L_L$  and  $C_P$ .

where  $\tau_{\text{resdel}}$  is the desired resonant delay,  $V_{\text{resdel}}$  is a voltage between 0V and 2V applied to the RESDEL pin, and DT is the deadtime (see Equations 1 through 5).

When the upper switches toggle, the primary current that was flowing through UL must find an alternate path. It charges/discharges the parasitic capacitance of switches UL and LL until the body diode of LL is forward biased. If RESDEL is set properly, switch LL will be turned on at this time. The output inductor does not assist this transition. It is purely a resonant transition driven by the leakage inductance.

**FIGURE 18. UPPER SWITCH TOGGLE AND RESONANT TRANSITION**

The second power transfer period commences when switch LL closes. With switches UR and LL on, the primary and secondary currents flow as indicated in Figure 19.

**FIGURE 19. UR - LL POWER TRANSFER CYCLE**

The UR - LL power transfer period terminates when switch LL turns off as determined by the PWM. The current flowing in the primary must find an alternate path. The current flows into the parasitic switch capacitance which charges the node to  $V_{IN}$  and then forward biases the body diode of upper switch UL. As before, the output inductor current assists in this transition. The primary leakage inductance,  $L_L$ , maintains the current, which now circulates around the path of switch UR, the transformer primary, and switch UL. When switch  $L_L$  opens, the output inductor current free-wheels predominantly through diode D1. Diode D2 may actually conduct very little or none of the free-wheeling current, depending on circuit parasitics. This condition persists through the remainder of the half-cycle.

**FIGURE 20. UR - UL FREE-WHEELING PERIOD**

When the upper switches toggle, the primary current that was flowing through UR must find an alternate path. It charges/discharges the parasitic capacitance of switches UR and LR until the body diode of LR is forward biased. If RESDEL is set properly, switch LR will be turned on at this time.

**FIGURE 21. UPPER SWITCH TOGGLE AND RESONANT TRANSITION**

The first power transfer period commences when switch LR closes and the cycle repeats. The ZVS transition requires that the leakage inductance has sufficient energy stored to fully charge the parasitic capacitances. Since the energy stored is proportional to the square of the current ( $1/2 L_L I_p^2$ ), the ZVS resonant transition is load dependent. If the leakage inductance is not able to store sufficient energy for ZVS, a discrete inductor may be added in series with the transformer primary.

## Synchronous Rectifier Outputs and Control

The ISL78223 provides double-ended PWM outputs, OUTLL and OUTLR, and synchronous rectifier (SR) outputs, OUTLLN and OUTLRN. The SR outputs are the complements of the PWM outputs. It should be noted that the complemented outputs are used in conjunction with the opposite PWM output, i.e., OUTLL and OUTLRN are paired together and OUTLR and OUTLLN are paired together.

**FIGURE 22. BASIC WAVEFORM TIMING**

Referring to Figure 22, the SRs alternate between being both on during the free-wheeling portion of the cycle (OUTLL/LR off), and one or the other being off when OUTLL or OUTLR is on. If OUTLL is on, its corresponding SR must also be on, indicating that OUTLRN is the correct SR control signal. Likewise, if OUTLR is on, its corresponding SR must also be on, indicating that OUTLLN is the correct SR control signal.

A useful feature of the ISL78223 is the ability to vary the phase relationship between the PWM outputs (OUTLL, OUTLR) and the their complements (OUTLLN, OUTLRN) by  $\pm 300\text{ns}$ . This feature allows the designer to compensate for differences in the propagation times between the PWM FETs and the SR FETs. A voltage applied to  $V_{ADJ}$  controls the phase relationship.

**FIGURE 23. WAVEFORM TIMING WITH PWM OUTPUTS DELAYED,  $0\text{V} < V_{ADJ} < 2.425\text{V}$**

**FIGURE 24. WAVEFORM TIMING WITH SR OUTPUTS DELAYED,  $2.575\text{V} < V_{ADJ} < 5.00\text{V}$**

Setting  $V_{ADJ}$  to  $V_{REF}/2$  results in no delay on any output. The no delay voltage has a  $\pm 75\text{mV}$  tolerance window. Control voltages below the  $V_{REF}/2$  zero delay threshold cause the PWM outputs, OUTLL/LR, to be delayed. Control voltages greater than the  $V_{REF}/2$  zero delay threshold cause the SR outputs, OUTLLN/LRN, to be delayed. It should be noted that when the PWM outputs, OUTLL/LR, are delayed, the CS to output propagation delay is increased by the amount of the added delay.

The delay feature is provided to compensate for mismatched propagation delays between the PWM and SR outputs as may be experienced when one set of signals crosses the primary-secondary isolation boundary. If required, individual output pulses may be stretched or compressed as required using external resistors, capacitors, and diodes.

When the PWM outputs are delayed, the 50% upper outputs are equally delayed, so the resonant delay setting is unaffected.

## On/Off Control

The ISL78223 does not have a separate enable/disable control pin. The PWM outputs, OUTLL/OUTLR, may be disabled by pulling VERR to ground. Doing so reduces the duty cycle to zero, but the upper 50% duty cycle outputs, OUTUL/OUTUR, will continue operation. Likewise, the SR outputs OUTLLN/OUTLRN will be active high.

Pulling Soft-Start to ground will disable all outputs and set them to a low condition.

## Fault Conditions

A fault condition occurs if  $V_{REF}$  or  $V_{DD}$  fall below their undervoltage lockout (UVLO) thresholds or if the thermal protection is triggered. When a fault is detected the outputs are disabled low. When the fault condition clears the outputs are re-enabled.

An overcurrent condition is not considered a fault and does not result in a shutdown.

## Thermal Protection

Internal die over temperature protection is provided. An integrated temperature sensor protects the device should the junction temperature exceed +140 °C. There is approximately +15 °C of hysteresis.

## Ground Plane Requirements

Careful layout is essential for satisfactory operation of the device. A good ground plane must be employed.  $V_{DD}$  and  $V_{REF}$  should be bypassed directly to GND with good high frequency capacitance.

## About Intersil

Intersil Corporation is a leader in the design and manufacture of high-performance analog, mixed-signal and power management semiconductors. The company's products address some of the largest markets within the industrial and infrastructure, personal computing and high-end consumer markets. For more information about Intersil, visit our website at [www.intersil.com](http://www.intersil.com).

For the most updated datasheet, application notes, related documentation and related parts, please see the respective product information page found at [www.intersil.com](http://www.intersil.com). You may report errors or suggestions for improving this datasheet by visiting [www.intersil.com/en/support/ask-an-expert.html](http://www.intersil.com/en/support/ask-an-expert.html). Reliability reports are also available from our website at <http://www.intersil.com/en/support/qualandreliability.html#reliability>

For additional products, see [www.intersil.com/en/products.html](http://www.intersil.com/en/products.html)

Intersil Automotive Qualified products are manufactured, assembled and tested utilizing TS16949 quality systems as noted in the quality certifications found at [www.intersil.com/en/support/qualandreliability.html](http://www.intersil.com/en/support/qualandreliability.html)

*Intersil products are sold by description only. Intersil Corporation reserves the right to make changes in circuit design, software and/or specifications at any time without notice. Accordingly, the reader is cautioned to verify that data sheets are current before placing orders. Information furnished by Intersil is believed to be accurate and reliable. # Package Outline Drawing

## M20.15

20 LEAD QUARTER SIZE OUTLINE PLASTIC PACKAGE (QSOP)

Rev 2, 1/11

### NOTES:

1. Symbols are defined in the "MO Series Symbol List" in Section 2.2 of Publication Number 95.
2. Dimensioning and tolerancing conform to AMSE Y14.5m-1994.
3. Dimension does not include mold flash, protrusions or gate burrs. Mold flash, protrusion and gate burrs shall not exceed 0.15mm (0.006 inch) per side.
4. Dimension does not include interlead flash or protrusions. Interlead flash and protrusions shall not exceed 0.25mm (0.010 inch) per side.
5. The chamfer on the body is optional. If it is not present, a visual index feature must be located within the crosshatched area.
6. Length of terminal for soldering to a substrate.
7. Terminal numbers are shown for reference only.
8. Dimension does not include dambar protrusion. Allowable dambar protrusion shall be 0.10mm (0.004 inch) total in excess of dimension at maximum material condition.
9. Controlling dimension: INCHES. Converted millimeter dimensions are not necessarily exact.
