

ISL8120IR

Dual/n-Phase Buck PWM Controller with Integrated Driver

FN6763

Rev.2.00

November 11, 2011

The ISL8120IRZEC integrates two voltage-mode synchronous buck PWM controllers to control a dual independent voltage regulator or a 2-phase single output regulator. It has PLL circuits and can output a phase-shift-programmable clock signal for the system to be expanded to 3-, 4-, 6-, 12- phases with desired interleaving phase shift. It also integrates current sharing control for the power module to operate in parallel, which offers high system flexibility.

It has voltage feed forward compensation to maintain a constant loop gain for optimal transient response, especially for applications with a wide input voltage range. Its integrated high speed MOSFET drivers and multi-feature functions provide complete control and protection for a 2/n-phase synchronous buck converter, dual independent regulators, or DDR tracking applications (VDDQ and VTT outputs).

The output voltage of a ISL8120IRZEC-based converter can be precisely regulated to as low as the internal reference voltage 0.6V, with a system accuracy of $\pm 0.9\%$ over industrial temperature and line load variations. Channel 2 can track an external ramp signal for DDR/tracking applications.

The ISL8120IRZEC integrates an internal linear regulator, which generates VCC from input rail for applications with only one single supply rail. The internal oscillator is adjustable from 150kHz to 1.5MHz, and is able to track an external clock signal for frequency synchronization and phase paralleling applications. The integrated Pre-Biased Digital Soft-Start, Differential Remote Sensing Amplifier, and Programmable Input Voltage POR features enhance the value of ISL8120IRZEC.

The ISL8120IRZEC protects against overcurrent conditions by inhibiting the PWM operation while monitoring the current with $r_{DS(ON)}$ of the lower MOSFET, DCR of the output inductor, or a precision resistor. It also has a PRE-POR Overvoltage Protection option, which provides some protection to the load device if the upper MOSFET(s) is shorted. See "PRE-POR Overvoltage Protection (PRE-POR-OVP)" on page 24 for details.

The ISL8120IRZEC's Fault Hand Shake feature protects any channel from overloading/stressing due to system faults or phase failure. The undervoltage fault protection features are also designed to prevent a negative transient on the output voltage during falling down. This eliminates the Schottky diode that is used in some systems for protecting the load device from reversed output voltage damage.

Features

- Full Traceability Through Assembly and Test by Date/Trace Code Assignment
- Enhanced Process Change Notification per MIL-PRF-38535
- Enhanced Obsolescence Management
- Wide VIN Range Operation: 3V to 22V
 - VCC Operation from 3V to 5.60V
- Fast Transient Response
 - 80MHz Bandwidth Error Amplifier
 - Voltage-Mode PWM Leading-Edge Modulation Control
 - Voltage Feed-Forward
- Dual Channel 5V High Speed 4A MOSFET Gate Drivers
 - Internal Bootstrap Diodes
- Internal Linear Regulator Provides a 5.4V Bias from VIN
- External Soft-Start Ramp Reference Input for DDR/Tracking Applications
- Excellent Output Voltage Regulation
 - 0.6V $\pm 0.6\%/\pm 0.9\%$ Internal Reference Over Industrial Temperature
 - True Differential Remote Voltage Sensing
- Oscillator Programmable from 150kHz to 1.5MHz
- Frequency Synchronization
- Scale for 1-, 2-, 3-, 4-, 6-, up to 12- Phase with Single Output
 - Excellent Phase Current Balancing
 - Programmable Phase Shift Between the 2 Phases Controlled by the ISL8120IRZEC and Programmable Phase Shift for Clockout Signal
 - Interleaving Operation Results in Minimum Input RMS Current and Minimum Output Ripple Current
- Fault Hand Shake Capability for High System Reliability
- Overcurrent Protection
 - DCR, $r_{DS(ON)}$, or Precision Resistor Current Sensing
 - Independent and Average Phase Current OCP
- Output Overvoltage and Undervoltage Protections
- Programmable Phase Shift in Dual Mode Operation
- Digital Soft-Start with Pre-Charged Output Start-up Capability
- Power-Good Indication
- Dual Independent Channel Enable Inputs with Precision Voltage Monitor and Voltage Feed-Forward Capability
 - Programmable Input Voltage POR and its Hysteresis with a Resistor Divider at EN Input

- Over-Temperature Protection
- Pre-Power-On-Reset Overvoltage Protection Option
- 32 Ld 5x5 QFN Package - Near Chip-Scale Footprint
 - Enhanced Thermal Performance for MHz Applications
- Pb-Free (RoHS compliant)

Applications

- Power Supply for Datacom/Telecom and POL
- Paralleling Power Module
- Wide and Narrow Input Voltage Range Buck Regulators
- DDR I and II Applications
- High Current Density Power Supplies
- Multiple Outputs VRM and VRD

Pinout

Ordering Information

PART NUMBER (Note)	PART MARKING	TEMP. RANGE (°C)	PACKAGE (Pb-free)	PKG. DWG. #
ISL8120IRZEC	ISL8120 IRZ	-40 to +85	32 Ld QFN	L32.5x5B
ISL8120IRZ-TEC*	ISL8120 IRZ	-40 to +85	32 Ld QFN	L32.5x5B

*Please refer to TB347 for details on reel specifications.

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Typical Application III (2-Phase Operation with $r_{DS(ON)}$ Sensing and Voltage Trimming)

Typical Application IV (3-Phase Regulator with Precision Resistor Sensing)

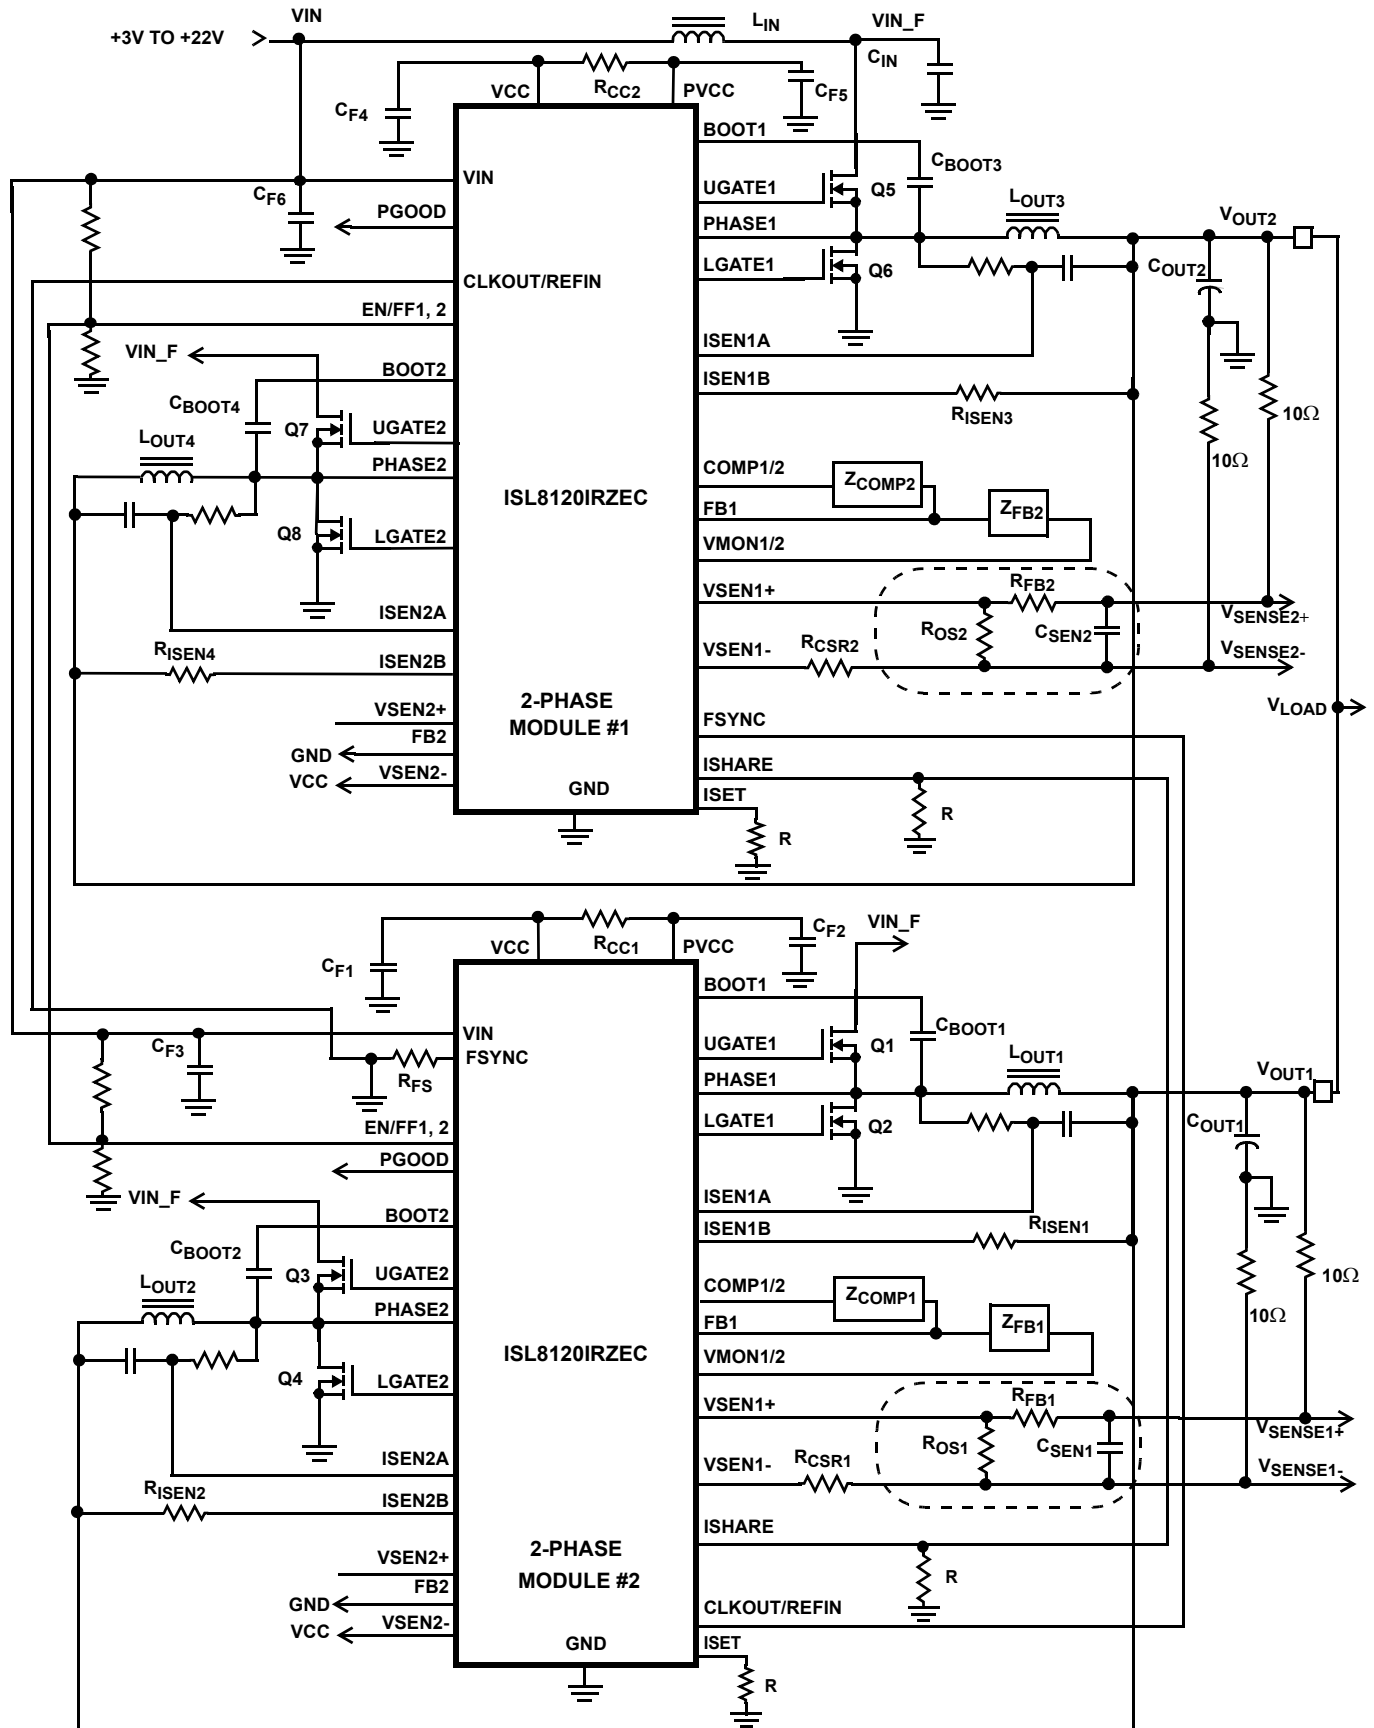

Typical Application V (4 Phase Operation with DCR Sensing)

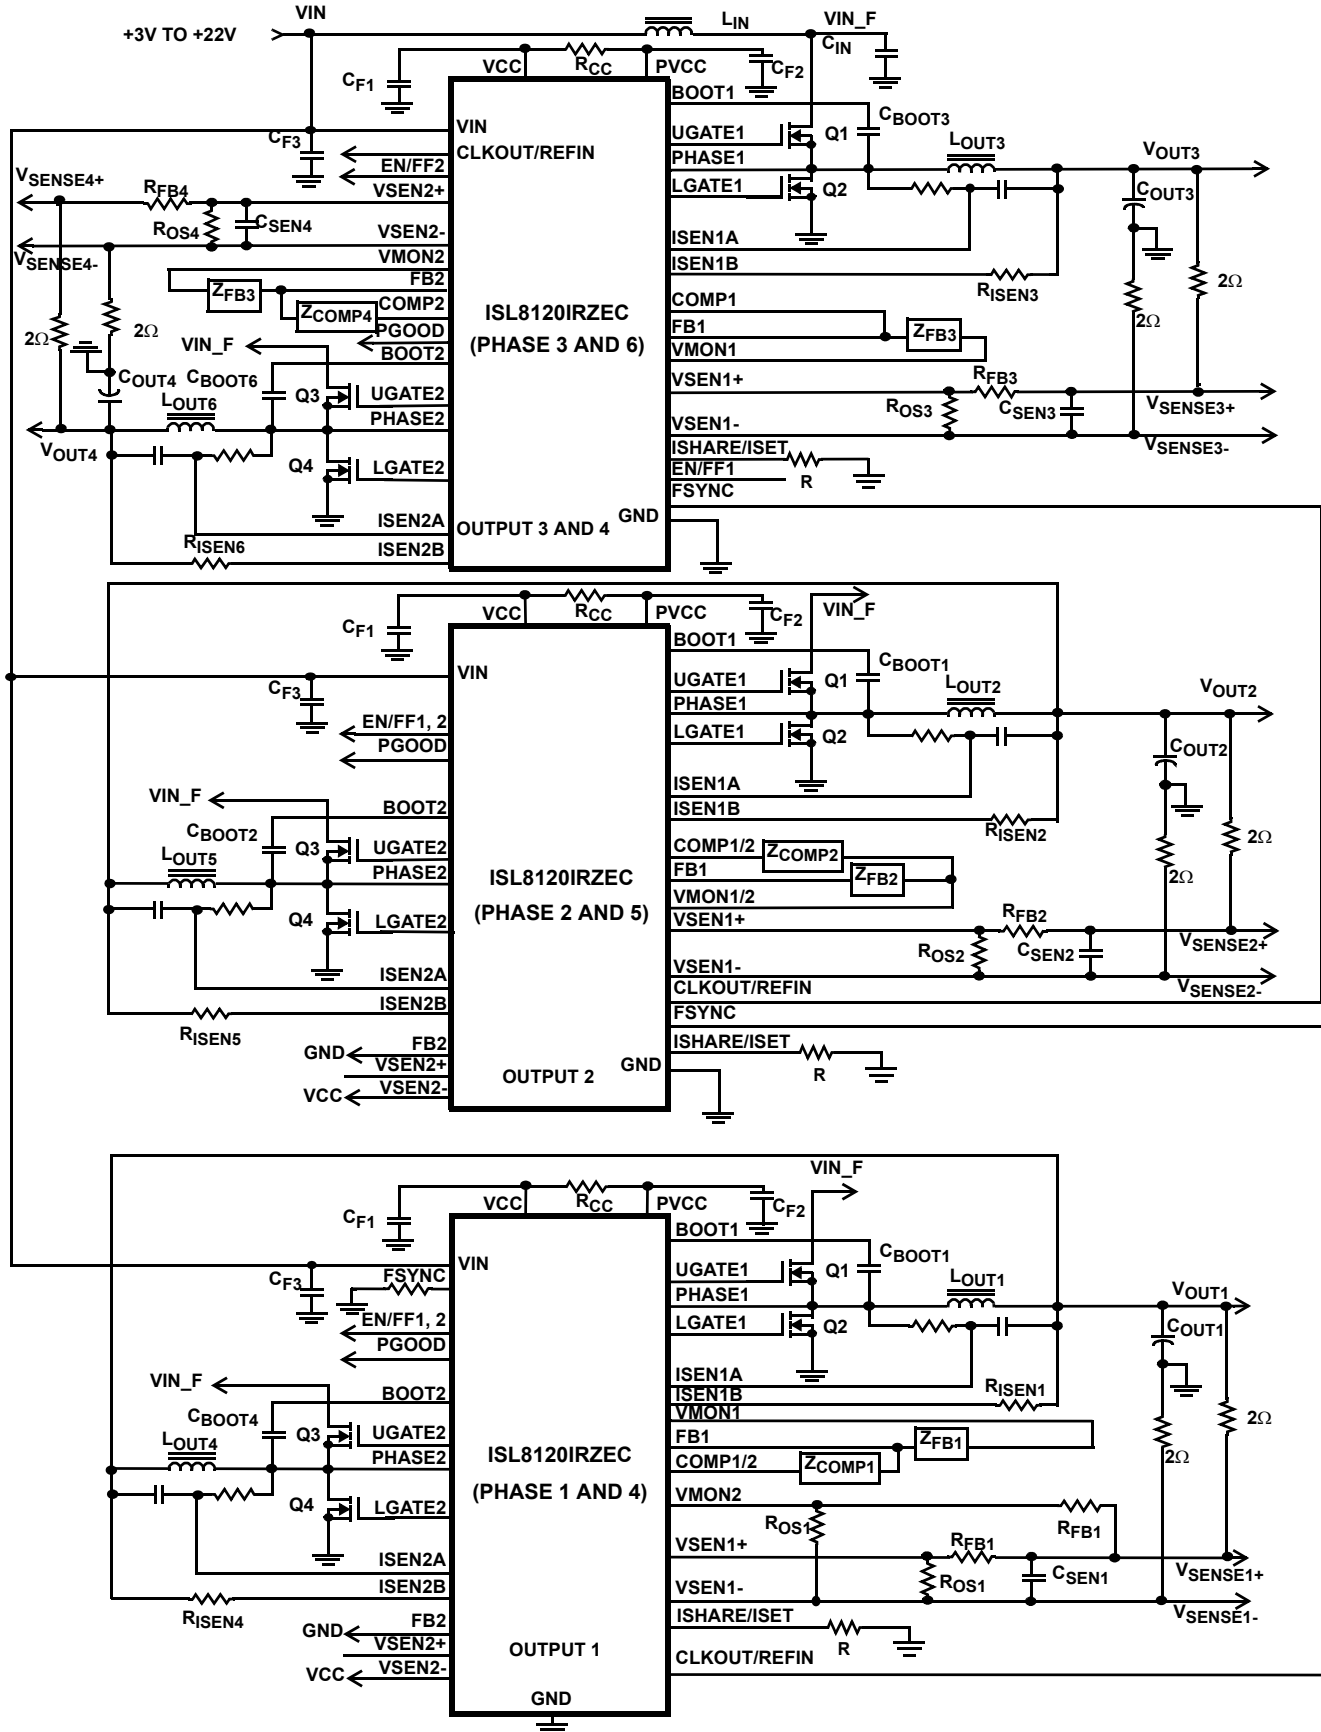

Typical Application VIII (Multiple Power Modules in Parallel with Current Sharing Control)

Typical Application VIII (4 Outputs Operation with DCR Sensing)

Absolute Maximum Ratings

Input Voltage, VIN	-0.3V to +27V
Driver Bias Voltage, PVCC	-0.3V to +6.5V
Signal Bias Voltage, VCC	-0.3V to +6.5V
BOOT/UGATE Voltage, VBOOT	-0.3V to +36V
Phase Voltage, VPHASE	VBOOT - 7V to VBOOT + 0.3V
BOOT to PHASE Voltage, VBOOT - VPHASE	-0.3V to VCC + 0.3V
Input, Output or I/O Voltage	-0.3V to VCC + 0.3V

Thermal Information

Thermal Resistance (Typical Notes 1, 2)	$\theta_{JA} (^{\circ}\text{C}/\text{W})$	$\theta_{JC} (^{\circ}\text{C}/\text{W})$
32 Ld QFN Package	32	3.5
Maximum Junction Temperature	-55°C to +150°C	
Maximum Storage Temperature Range	-65°C to +150°C	
Pb-free Reflow Profile	see link below	
http://www.intersil.com/pbfree/Pb-FreeReflow.asp		

Recommended Operating Conditions

Input Voltage, VIN	3V to 22V
Driver Bias Voltage, PVCC	3V to 5.6V
Signal Bias Voltage, VCC	3V to 5.6V
Boot to Phase Voltage (Overcharged), VBOOT - VPHASE	<6V
Industrial Ambient Temperature Range	-40°C to +85°C
Maximum Junction Temperature Range	+125°C

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

NOTES:

1. θ_{JA} is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features.
2. For θ_{JC} , the "case temp" location is the center of the exposed metal pad on the package underside.
3. Limits should be considered typical and are not production tested.

Electrical Specifications Recommended Operating Conditions, Unless Otherwise Noted. Parameters with MIN and/or MAX limits are 100% tested at +25°C, unless otherwise specified. Temperature limits established by characterization and are not production tested.

Functional Pin Description

GND (Pin 33, Signal and Power Ground Pad)

All voltage levels are referenced to this pad. This pad provides a return path for the low-side MOSFET drives and internal power circuitries as well as all analog signals. Connect this pad to the circuit ground using the shortest possible path (more than 5 to 6 via to the internal ground plane, placed on the soldering pad are recommended).

VIN (Pin 16, Internal Linear Regulator Input)

This pin should be tied directly to the input rail when using the internal linear regulator. It provides power to the internal linear drive circuitry. When used with an external 5V supply, this pin should be tied directly to PVCC. The internal linear device is protected against reverse bias generated by the remaining charge of the decoupling capacitor at PVCC when losing the input rail.

VCC (Pin 26, Analog Circuit Bias)

This pin provides power for the analog circuitry. A RC filter is recommended between the connection of this pin to a 3V to 5.6V bias (typically PVCC). R is suggested to be a 5Ω resistor. And in 3.3V applications, the R could be shorted to allow the low end input in concerns of the VCC falling threshold. The VCC decoupling cap C is strongly recommended to be as large as 10μF ceramic capacitor. This pin can be powered either by the internal linear regulator or by an external voltage source.

BOOT1, 2 (Pins 25, 17)

This pin provides the bootstrap bias for the high-side driver. Internal bootstrap diodes connected to the PVCC pin provide the necessary bootstrap charge. Its typical operational voltage range is 2.5V to 5.6V.

UGATE1, 2 (Pin 24, 8)

These pins provide the drive for the high-side devices and should be connected to the MOSFETs' gates.

PHASE1, 2 (Pins 23, 19)

Connect these pins to the source of the high-side MOSFETs and the drain of the low-side MOSFETs. These pins represent the return path for the high-side gate drives.

PVCC (Pin 21, Driver Bias Voltage)

This pin is the output of the internal series linear regulator. It provides the bias for both low-side and high-side drives. Its operational voltage range is 3V to 5.6V. The decoupling ceramic capacitor in the PVCC pin is 10μF.

LGATE1, 2 (Pins 22, 20)

These pins provide the drive for the low-side devices and should be connected to the MOSFETs' gates.

FSYNC (Pin 5)

The oscillator switching frequency is adjusted by placing a resistor (R_{FS}) from this pin to GND. The internal oscillator

will lock to an external frequency source if this pin is connected to a switching square pulse waveform, typically the CLKOUT input signal from another ISL8120IRZEC or an external clock. The internal oscillator synchronizes with the leading edge of the input signal.

EN/FF1, 2 (Pins 4, 6)

These are triple function pins. The input voltages to these pins are compared with a precision 0.8V reference and enable their digital soft-starts. By pulling this pin to voltage lower than the threshold, the corresponding channel can be disabled independently. Connecting these pins to input bus through a voltage resistor divider can monitor the input voltage. The undervoltage lockout and its hysteresis levels can be programmed by setting the values of the resistor dividers. The voltages on these pins are also fed into controller to be used to adjust the amplitude of each individual sawtooth independently.

Furthermore, during fault (such as overvoltage, overcurrent, and over-temperature) conditions, these pins (EN/FF_) are used to communicate the information to other cascaded ICs by pulling low.

PGOOD (Pin 8)

Provides an open drain Power-Good signal when both channels are within 9% of nominal output regulation point with 4% hysteresis (13%/9%) and soft-start is complete. PGOOD monitors the outputs (VMON1/2) of the internal differential amplifiers.

ISEN1A, 2A (Pins 27, 15)

These pins are the positive inputs of the current sensing amplifier. Together with ISEN1B, 2B, these pins provide $r_{DS(ON)}$, DCR, or precision resistor current sensing.

ISEN1B, 2B (Pins 28, 14)

These pins are the negative inputs of the current sensing amplifier. Together with the ISEN1A, 2A pins they provide $r_{DS(ON)}$, DCR, or precision resistor current sensing. Refer to "Typical Application III (2-Phase Operation with $r_{DS(ON)}$ Sensing and Voltage Trimming)" on page 7 for $r_{DS(ON)}$ sensing set up and "Typical Application V (4 Phase Operation with DCR Sensing)" on page 9 for DCR sensing set-up.

ISSET (Pin 2)

This pin sources an 15μA offset current plus the average current of both channels in multiphase mode or only Channel 1's current in independent mode. The voltage (V_{ISSET}) set by an external resistor (R_{ISSET}) represents the average current level of the local active channel(s). V_{ISSET} is compared with a 1V threshold for average overcurrent protections. For full-scale current, R_{ISSET} should be $1V/120\mu A = 8.33k\Omega$. Typically 10kΩ is used for R_{SET} .

ISHARE (Pin 3)

This pin is used for current sharing purposes and is configured to current share bus representing all modules' average current. It sources 15µA offset current plus the average current of both channels in multiphase mode or Channel 1's current in independent mode. The share bus (ISHARE pins connected together) voltage (V_{ISHARE}) set by an external resistor (R_{ISHARE}) represents the average current level of all active channel(s). The ISHARE bus voltage compares with each reference voltage set by each R_{ISET} and generates current share error signal for current correction block of each cascaded controller. The share bus impedance R_{ISHARE} should be set as R_{ISET}/N_{CTRL} (R_{ISET} divided by number of active current sharing controllers).

CLKOUT/REFIN (Pin 7)

This pin has a dual function depending on the mode in which the chip is operating. It provides clock signal to synchronize with other ISL8120(s) with its VSEN2- pulled within 700mV of VCC for multiphase (3-, 4-, 6-, 8-, 10-, or 12-phase) operation. When the VSEN2- pin is not within 700mV of VCC, ISL8120 is in dual mode (dual independent PWM output). The clockout signal of this pin is not available in this mode, but the ISL8120 can be synchronized to external clock. In dual mode, this pin works as the following two functions:

1. An external reference (0.6V target only) can be in place of the Channel 2's internal reference through this pin for DDR/tracking applications (see "Internal Reference and System Accuracy" on page 31).
2. The ISL8120IRZEC operates as a dual-PWM controller for two independent regulators with selectable phase degree shift, which is programmed by the voltage level on REFIN (see "DDR and Dual Mode Operation" on page 30).

FB1, 2 (Pins 32, 10)

These pins are the inverting inputs of the error amplifiers. These pins should be connected to VMON1, 2 with the compensation feedback network. No direct connection between FB and VMON pins is allowed. With VSEN2- pulled within 700mV of VCC, the corresponding error amplifier is disabled and the amplifier's output is high impedance. FB2 is one of the two pins to determine the relative phase relationship between the internal clock of both channels and the CLKOUT signal. See "DDR and Dual Mode Operation" on page 30.

COMP1, 2 (Pins 1, 9)

These pins are the error amplifier outputs. They should be connected to FB1, 2 pins through desired compensation networks when both channels are operating independently. When VSEN1-, 2- are pulled within 700mV of VCC, the corresponding error amplifier is disabled and its output (COMP pin) is high impedance. Thus, in multiphase operations, all other SLAVE phases' COMP pins can tie to

the MASTER phase's COMP1 pin (1st phase), which modulates each phase's PWM pulse with a single voltage feedback loop. While the error amplifier is not disabled, an independent compensation network is required for each cascaded IC.

VSEN1+, 2+ (Pins 29, 13)

These pins are the positive inputs of the standard unity gain operational amplifier for differential remote sense for the corresponding channel (Channel 1 and 2), and should be connected to the positive rail of the load/processor. These pins can also provide precision output voltage trimming capability by pulling a resistor from this pin to the positive rail of the load (trimming down) or the return (typical VSEN1-2-pins) of the load (trimming up). The typical input impedance of VSEN+ with respect to VSEN- is 500kΩ. By setting the resistor divider connected from the output voltage to the input of the differential amplifier, the desired output voltage can be programmed. To minimize the system accuracy error introduced by the input impedance of the differential amplifier, a 100Ω or less resistor is recommended to be used for the lower leg (R_{OS}) of the feedback resistor divider.

With VSEN2- pulled within 700mV of VCC, the corresponding error amplifier is disabled and VSEN2+ is one of the two pins to determine the relative phase relationship between the internal clock of both channels and the CLKOUT signal. See "DDR and Dual Mode Operation" on page 30 for details.

VSEN1-, 2- (Pins 30, 12)

These pins are the negative inputs of standard unity gain operational amplifier for differential remote sense for the corresponding regulator (Channel 1 and 2), and should be connected to the negative rail of the load/processor.

When VSEN1-, 2- are pulled within 700mV of VCC, the corresponding error amplifier and differential amplifier are disabled and their outputs are high impedance. Both VSEN2+ and FB2 input signal levels determine the relative phases between the internal controllers as well as the CLKOUT signal. See "DDR and Dual Mode Operation" on page 30 for details.

When configured as multiple power modules (with independent voltage loop) operating in parallel, in order to implement the current sharing control, a resistor needs to be inserted between VSEN1- pin and output voltage negative sense point (between VSEN1- and lower voltage sense resistor), as shown in the "Typical Application VIII (Multiple Power Modules in Parallel with Current Sharing Control)" on page 12. This introduces a correction voltage for the modules with lower load current to keep the current distribution balanced among modules. The module with the highest load current will automatically become the master module. The recommended value for the VSEN1- resistor is

100Ω and it should not be large in order to keep the unit gain amplifier input impedance compatibility.

VMON1, 2 (Pins 31, 11)

These pins are outputs of the unity gain amplifiers. They are connected internally to the OV/UV/PGOOD comparators. These pins should be connected to the FB1, 2 pins by a standard feedback network when both channels operating independently. When VSEN1-, 2- are pulled within 700mV of VCC, the corresponding differential amplifier is disabled and its output (VMON pin) is high impedance. In such an event, the VMON pin can be used as an additional monitor of the output voltage with a resistor divider to protect the system against single point of failure, which occurs in the system using the same resistor divider for both of the UV/OV comparator and output voltage feedback.

Modes of Operation

There are 9 typical operation modes depending upon the signal levels on EN1/FF1, EN2/FF2, VSEN2+, VSEN2-, FB2, and CLKOUT/REFIN.

MODE 1: The IC is completely disabled when EN1/FF1 and EN2/FF2 are pulled below 0.8V.

MODE 2: With EN1/FF1 pulled low and EN2/FF2 pulled high (Mode 2A), or EN1/FF1 pulled high and EN2/FF2 pulled low (Mode 2B), the ISL8120IRZEC operates as a single phase regulator. the current sourcing out from the ISHARE pin represents the first channel current plus 15μA offset current.

MODE 3: When VSEN2- is used as a negative sense line, both channels' phase shift depends upon the voltage level of CLKOUT/REFIN. When the CLKOUT/REFIN pin is within 29% to 45% of VCC, Channel 2 delays 0° over Channel 1 (Mode 3A); when within 45% to 62% of VCC, 90° delay (Mode 3B); when greater than 62% to VCC, 180° delay (Mode 3C). Refer to the "DDR and Dual Mode Operation" on page 30.

MODE 4: When VSEN2- is used as a negative remote sense line, and CLKOUT/REFIN is connected to a external voltage ramp lower than the internal soft-start ramp and lower than 0.6V, the external ramp signal will replaces Channel 2's internal soft-start ramp to be tracked at start-up, controller operating in DDR mode. The controller will use the lowest voltage among the internal 0.6V reference, the external voltage in CLKOUT/REFIN pin and the soft-start ramp signal. Channel 1 is delayed 60° behind Channel 2. Refer to the "DDR and Dual Mode Operation" on page 30.

MODE 5: With VSEN2- pulled within 700mV of VCC and FB2 pulled to ground, the internal channels are 180° out-of-phase and operate in 2-phase single output mode (5A). The CLKOUT/REFIN pin (rising edge) also signals out clock with 60° phase shift relative to the Channel 1's clock signal (falling edge of PWM) for 6-phase operation with two other ISL8120IRZECs (5B). When the share Pins are not connected to each other for the three ICs in sync, two of which can operate in Mode 5A (3 independent outputs can be generated (Mode 5D)) and Modes 3 and 4 (to generate 4 independent outputs (Mode 5C)) respectively.

MODE 6: With VSEN2- pulled within 700mV of VCC, FB2 pulled high and VSEN2+ pulled low, the internal channels (as 1st and 3rd Phase, respectively) are 240° out-of-phase and operate in 3-phase single output mode, combined with another ISL8120IRZEC at MODE 2B. The CLKOUT/REFIN pin signals out 120° relative phases to the falling edge of Channel 1's clock signal to synchronize with the second ISL8120IRZEC's Channel 1 (as 2nd Phase).

MODE 7: With VSEN2- pulled within 700mV of VCC and FB2 and VSEN2+ pulled high, the internal channels is 180° out-of-phase. The CLKOUT/REFIN pin (rising edge) signals out 90° relative phase to the Channel 1's clock signal (falling edge of PWM) to synchronize with another ISL8120IRZEC, which can operate at Mode 3, 4, 5A, or 7A. A 4-phase single output converter can be constructed with two ISL8120IRZECs operating in Mode 5A or 7A (Mode 7A). If the share bus is not connected between ICs, each IC could generate an independent output (Mode 7B). When the second ISL8120IRZEC operates as two independent regulators (Mode 3) or in DDR mode (Mode 4), then three independent output system is generated (Mode 7C). Both ICs can also be constructed as a 3-phase converter (0°, 90°, and 180°, not a equal phase shift for 3-phase) with a single phase regulator (270°).

MODE 8: The output CLKOUT signal allows expansion for 12-phase operation with the cascaded sequencing as shown in Table 1. No external clock is required in this mode for the desired phase shift.

MODE 9: With an external clock, the part can be expanded for 5, 7, 8, 9 10 and 11 phase single output operation with the desired phase shift.

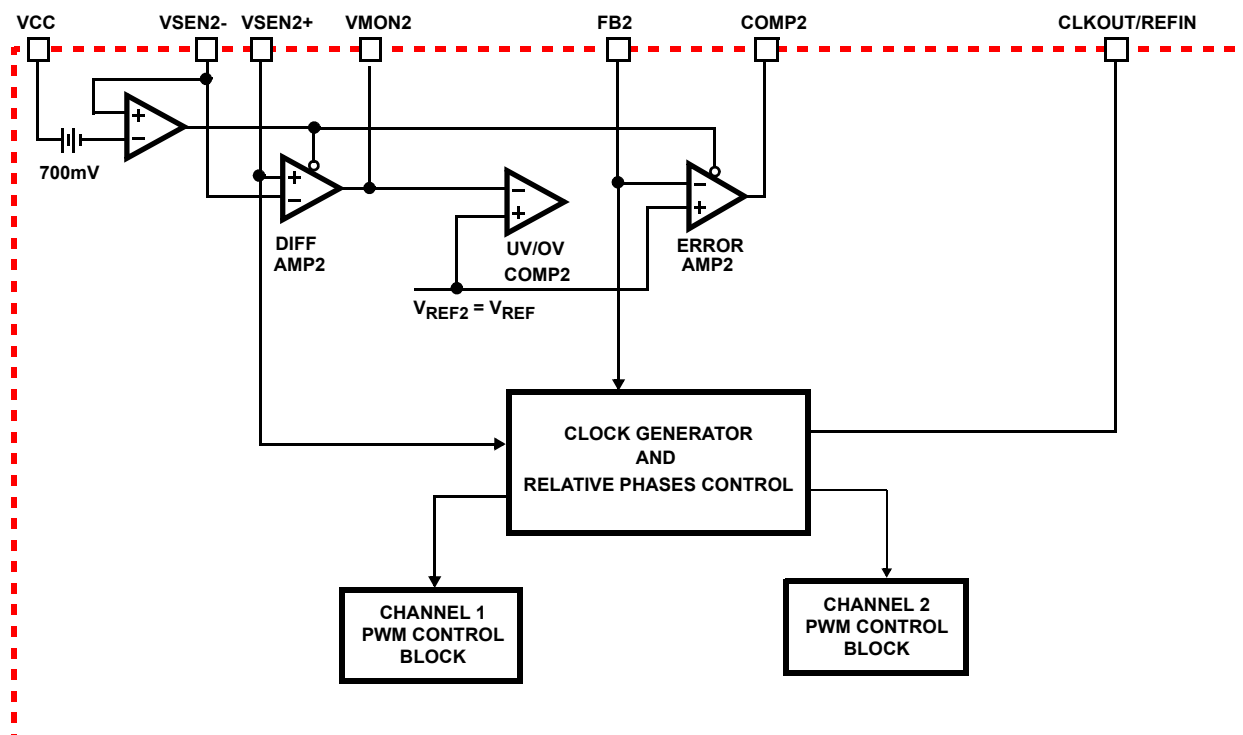

FIGURE 3. SIMPLIFIED RELATIVE PHASES CONTROL

Functional Description

Initialization

Initially, the ISL8120IRZEC Power-On Reset (POR) circuits continually monitor the bias voltages (PVCC and VCC) and the voltage at EN pin. The POR function initiates soft-start operation 384 clock cycles after the EN pin voltage is pulled to be above 0.8V, all input supplies exceed their POR thresholds and the PLL locking time expires, as shown in Figure 4. The enable pin can be used as a voltage monitor and to set desired hysteresis with an internal 30μA sinking current going through an external resistor divider. The sinking current is disengaged after the system is enabled. This feature is especially designed for applications that require higher input rail POR for better undervoltage protection. For example, in 12V applications, $R_{UP} = 53.6k$ and $R_{DOWN} = 5.23k$ will set the turn-on threshold (V_{EN_RTH}) to 10.6V and turn-off threshold (V_{EN_FTH}) to 9V, with 1.6V hysteresis (V_{EN_HYS}).

During shutdown or fault conditions, the soft-start is reset quickly while UGATE and LGATE changes states immediately (<100ns) upon the input drops below falling POR.

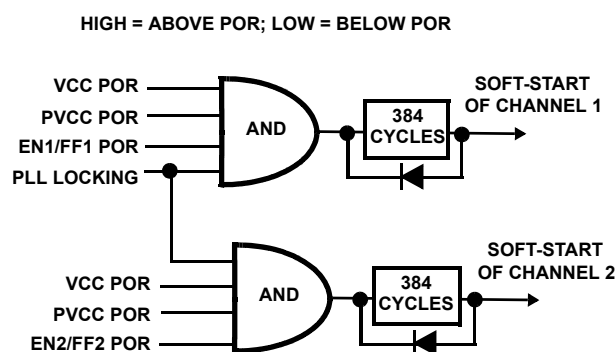

FIGURE 4. SOFT-START INITIALIZATION LOGIC

$$R_{UP} = \frac{V_{EN_HYS}}{I_{EN_HYS}} \quad R_{DOWN} = \frac{R_{UP} \cdot V_{EN_REF}}{V_{EN_ETH} - V_{EN_REF}}$$

$$V_{EN\ FTH} = V_{EN\ RTH} - V_{EN\ HYS}$$

$$\Delta V_{\text{RAMP}} = \text{LIMIT}(V_{\text{CC FF}} \times G_{\text{RAMP}}, V_{\text{CC}} - 1.4\text{V} - V_{\text{RAMP OFFSET}})$$

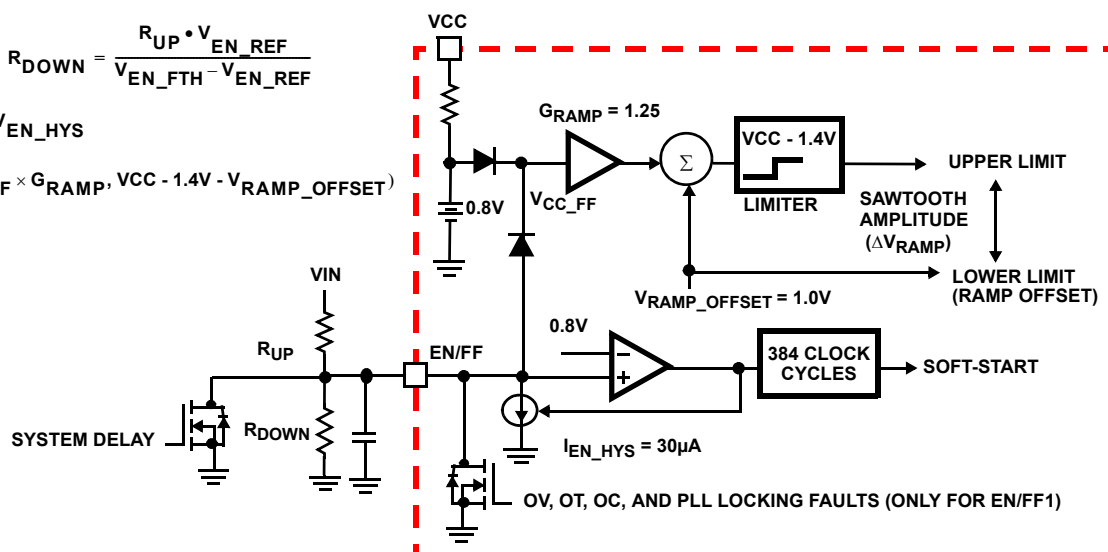

FIGURE 5. SIMPLIFIED ENABLE AND VOLTAGE FEEDFORWARD CIRCUIT

Voltage Feed-forward

Other than used as a voltage monitor described in previous section, the voltages applied to the EN/FF pins are also fed to adjust the amplitude of each channel's individual sawtooth. The amplitude of each channel's sawtooth is set to 1.25 times of the corresponding EN/FF voltage upon its enable (above 0.8V). This helps to maintain a constant gain ($G_M = V_{IN} \cdot D_{MAX} / \Delta V_{RAMP}$) contributed by the modulator and the input voltage to achieve optimum loop response over a wide input voltage range. The sawtooth ramp offset voltage is 1V (equal to $0.8V \cdot 1.25$), and the peak of the sawtooth is limited to $V_{CC} - 1.4V$. With $V_{CC} = 5.4V$, the ramp has a maximum peak-to-peak amplitude of $V_{CC} - 2.4V$ (equal to 3V); So the feed-forward voltage effective range is typically 3x as the ramp amplitude ranges from 1V to 3V.

A 384 cycle delay is added after the system reaches its rising POR and prior to the soft-start. The RC timing at the EN/FF pin should be sufficiently small to ensure that the input bus reaches its static state and the internal ramp circuitry stabilizes before soft-start. A large RC could cause the internal ramp amplitude not to synchronize with the input bus voltage during output start-up or when recovering from faults. It is recommended to use open drain or open collector to gate this pin for any system delay, as shown in Figure 5.

The multiphase system can immediately turn off all ICs under fault conditions of one or more phases by pulling all EN/FF pins low. Thus, no bouncing occurs among channels at fault and no single phase could carry all current and be over stressed.

FIGURE 6. TYPICAL 4-PHASE WITH FAULT HANDSHAKE

While EN/FF is pulled to ground, a constant voltage (0.8V) is fed into the ramp generator to maintain a minimum peak-to-peak ramp.

Since the EN/FF pins are pulled down under fault conditions, the pull-up resistor (R_{UP}) should be scaled to sink no more than 5mA current from EN/FF pin. Essentially, the EN/FF pins cannot be directly connected to VCC.

Soft-start

The ISL8120IRZEC has two independent digital pre-charged soft-start circuitry, which has a rise time inversely proportional to the switching frequency and is determined by a digital counter that increments with every pulse of the phase clock. Refer to Figure 7. The full soft-start time from 0V to 0.6V can be estimated by Equation 1.

$$t_{SS} = \frac{1280}{f_{SW}} \quad (\text{EQ. 1})$$

The ISL8120IRZEC has the ability to work under a pre-charged output (see Figure 8). The output voltage would not be yanked down during pre-charged start-up. If the pre-charged output voltage is greater than the final target level but prior to 113% setpoint, the switching will not start until the output voltage reduces to the target voltage and the first PWM pulse is generated (see Figure 9). The maximum allowable pre-charged level is 113%. If the pre-charged level is above 113% but below 120%, the output will hiccup between 113% (LGATE turns on) and 87% (LGATE turns off) while EN/FF is pulled low. If the pre-charged load voltage is above 120% of the targeted output voltage, then the controller will be latched off and not be able to power-up. See "PRE-POR Overvoltage Protection (PRE-POR-OVP)" on page 24 for details.

For above target pre-charged start-up, the output voltage would not change until the end of the soft-start. If the initial dip is below the UV level, the LGATE could be turned off. In such an event, the body-diode drop of the low-side FET will be sensed and could potentially cause an OCP event for $r_{DS(ON)}$ current sensing applications.

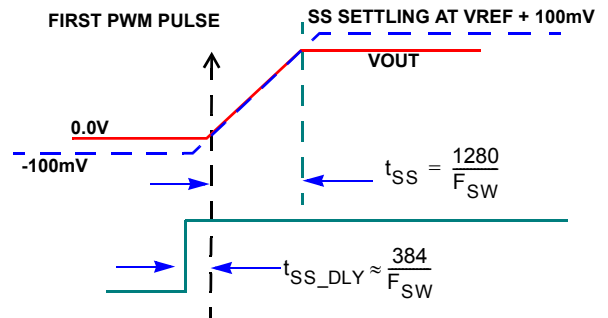

FIGURE 7. SOFT-START WITH VOUT = 0V

FIGURE 8. SOFT-START WITH VOUT = UV

FIGURE 9. SOFT-START WITH VOUT BELOW OV BUT ABOVE FINAL TARGET VOLTAGE

Power-Good

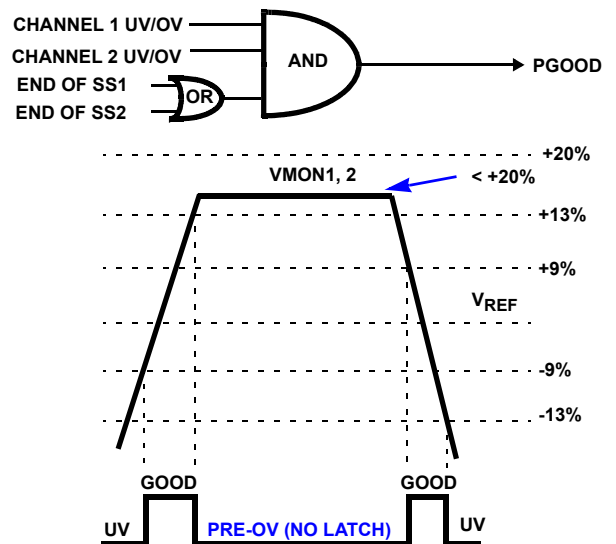

FIGURE 10. POWER-GOOD THRESHOLD WINDOW

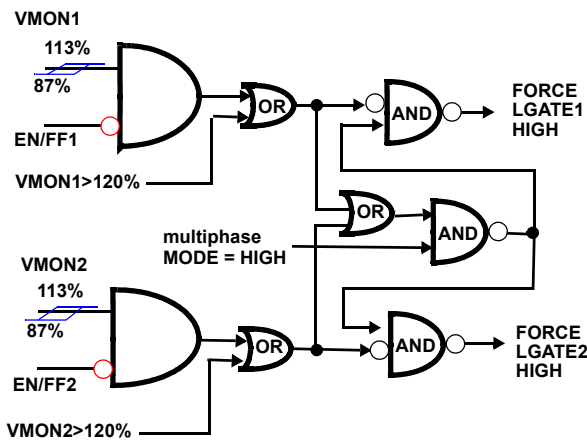

FIGURE 11. FORCE LGATE HIGH LOGIC

Both channels share the same PGOOD output. Either of the channels indicating out-of-regulation will pull-down the PGOOD pin. The Power-Good comparators monitor the voltage on the VMON pins. The trip points are shown in Figure 10. PGOOD will not be asserted until after the completion of the soft-start cycle of both channels. If Channels 1 or 2 are not used, the Power-Good can stay in operation by connecting 2 channels' VMON pins together. The PGOOD pulls low upon both EN/FF's disabling it if one of the VMON pins' voltage is out of the threshold window. PGOOD will not pull low until the fault presents for three consecutive clock cycles. In Dual/DDR application, if the turn-off channel pre-charges its VMON within the PGOOD threshold window, it could indicate Power-Good, however, the PGOOD signal can pull low with an external PNP or PMOS transistor via the EN/FF of the corresponding off channel.

Undervoltage and Overvoltage Protection

The Undervoltage (UV) and Overvoltage (OV) protection circuitry monitor the voltage on the VMON pins. The UV functionality is not enabled until the end of soft-start. An OV condition ($>120\%$) during soft-start would latch IC off.

In an UV event, if the output drops below -13% (-9% is the hysteresis level) due to some reasons other than OV, OC, OT, and PLL faults (EN/FF is not pulled low) of the target level at the output voltage falling edge, the lower MOSFETs will turn off to avoid any negative voltage ringing.

An OV event ($V_{OUT} > 120\%$) causes the high-side MOSFET to latch off permanently, while the low-side MOSFET turns on and then turns off after the output voltage drops below 87% . At the same time, the EN/FF and PGOOD are also latched low. The latch condition can be reset only by recycling VCC. In Dual/DDR mode, each channel is responsible for its own OV event with the corresponding VMON as the monitor. In multiphase mode, both channels respond simultaneously when either triggers an OV event.

To protect the overall power trains in case of only one channel of a multiphase system detecting OV, the low-side MOSFET always turns on at the conditions of EN/FF = LOW and the output voltage above 113% (all VMON pins and EN pins are tied together) and turns off after the output drops below 87% . Thus, in a high phase count application (Multiphase Mode), all cascaded ICs can latch off simultaneously via EN pins, and each IC shares the same sink current to reduce the stress and eliminate the bouncing among phases.

FIGURE 12. UV AND OV TIMING DIAGRAM

PRE-POR Overvoltage Protection (PRE-POR-OVP)

When both the VCC and PVCC are below PORs (not include EN POR), the UGATE is low and LGATE is floating (high impedance). EN/FF has no control on LGATE when below PORs. When above PORs, the LGATE would not be floating but toggling with its PWM pulses. An external 10Ω resistor, connected in between Phase and LGATE nodes, enables the PRE-POR-OVP circuit. The output of the converter that is equal to phase node voltage via output inductors is then effectively clamped to the low-side MOSFET's gate threshold voltage, which provides some protection to the microprocessor if the upper MOSFET(s) is shorted during start-up, shutdown, or normal operations. For complete protection, the low-side MOSFET should have a gate threshold that is much smaller than the maximum voltage rating of the load.

The PRE-POR-OVP works against pre-biased start-up when pre-charged output voltage is higher than the threshold of the low-side MOSFET, however, it can be disabled by placing a $2k\Omega$ resistor from LGATE to ground.

Over-Temperature Protection (OTP)

When the junction temperature of the IC is greater than $+150^\circ\text{C}$ (typically), both EN/FF pins pull low to inform other cascaded channels via their EN/FF pins. All connected EN/FFs stay low and release after the IC's junction temperature drops below $+125^\circ\text{C}$ (typically), with a $+25^\circ\text{C}$ hysteresis (typical).

Current Loop

When the ISL8120IRZEC operates in 2-phase mode, the current control loop keeps the channel's current in balance. After 175ns blanking period with respect to the falling edge of the PWM pulse of each channel, the voltage developed across the DCR of the inductor, $r_{DS(ON)}$ of the low-side MOSFETs, or a precision resistor, is filtered and sampled for 175ns. The current (I_{CS1}/I_{CS2}) is scaled by the R_{ISEN} resistor and provides feedback proportional to the average output current of each channel.

For DCR sensing, the ICS can be derived from Equation 2:

$$ICS = \frac{IL \cdot DCR}{RISEN} \quad (EQ. 2)$$

where I_L is the inductor DC current, and DCR is its DC resistance.

For low-side MOSFET $r_{DS(ON)}$ sensing, the ICS can be derived from Equation 3:

$$I_{CS} = \frac{I_L \cdot r_{DS(ON)}}{R_{ISEN}} \quad (\text{EQ. 3})$$

In multiphase mode (VSEN2- pulled high), the scaled output currents from both active channels are combined to create an average current reference (I_{AVG}) which represents average current of both channel outputs as calculated in Equation 4.

$$I_{AVG} = \frac{ICS1 + ICS2}{2} \quad (EQ. 4)$$

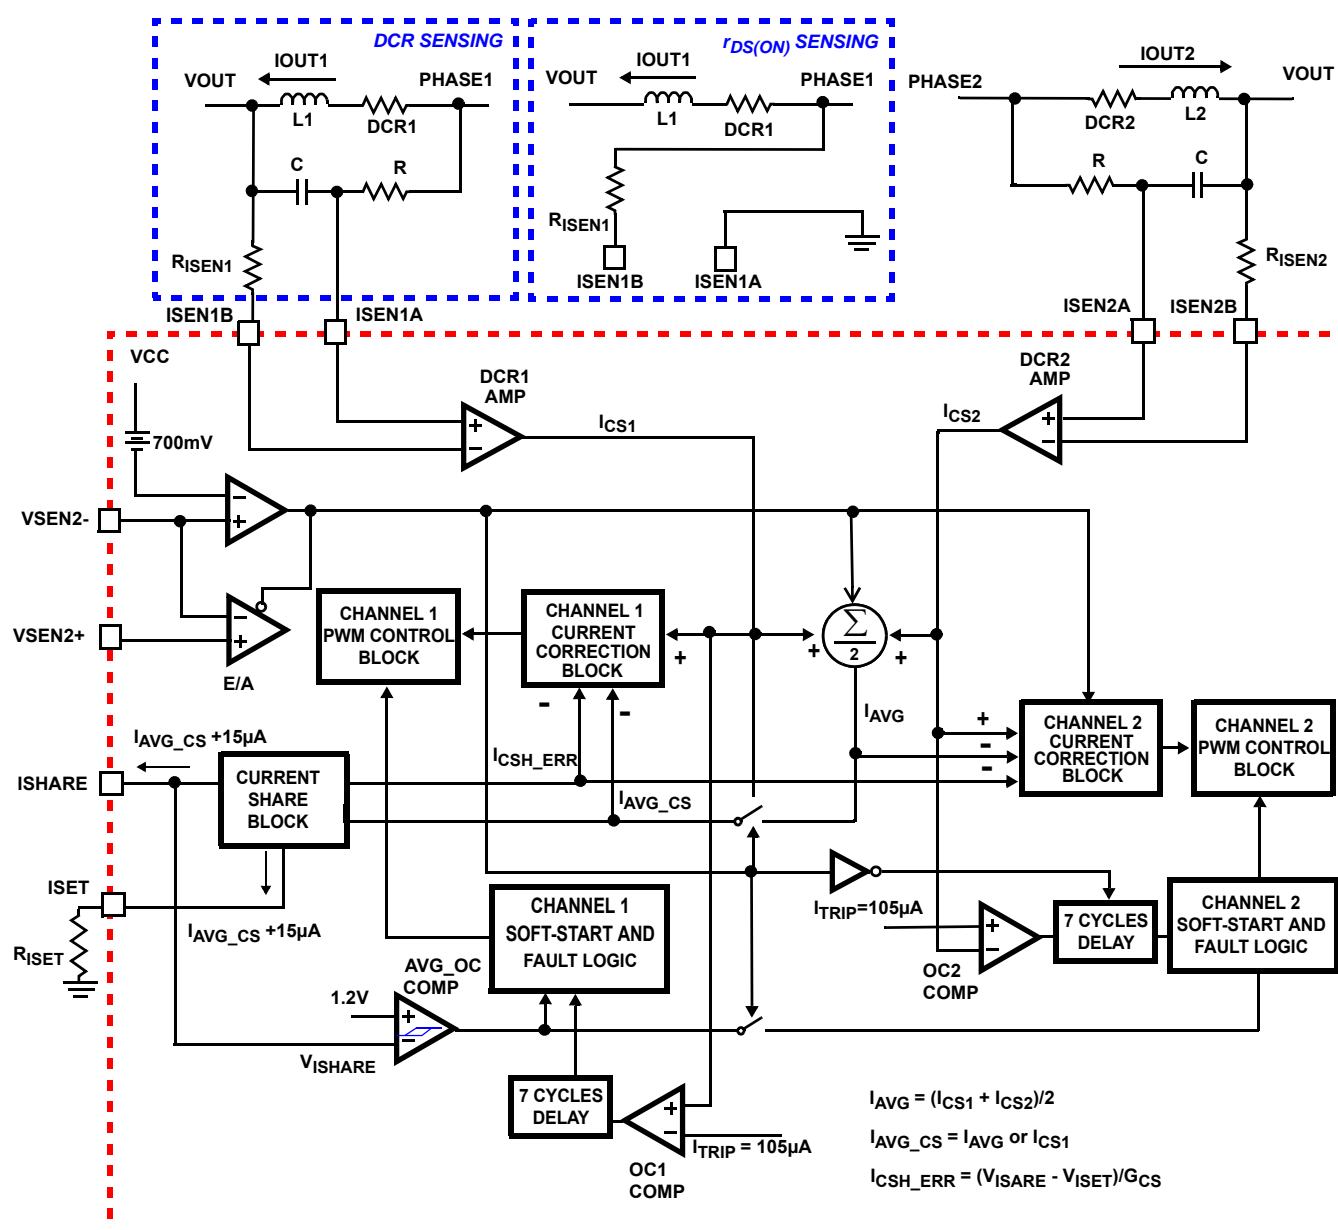

FIGURE 13. SIMPLIFIED CURRENT SAMPLING AND OVERCURRENT PROTECTION

The signal I_{AVG} is then subtracted from the individual channel's scaled current (I_{CS1} or I_{CS2}) to produce a current correction signal for each channel. The current correction signal keeps each channel's output current contribution balanced relative to the other active channel.

For multiphase operation, the share bus (V_{ISHARE}) represents the average current of all active channels and compares with each IC's average current (I_{AVG_CS} equals to I_{AVG} or I_{CS1} depending upon the configuration, represented by V_{ISET}) to generate current share error signal (I_{CSH_ERR}) for each individual channel. Each current correction signal is then subtracted from the error amplifier output and fed to the individual channel PWM circuits.

When both channels operate independently, the average function is disabled and generates zero average current ($I_{AVG} = 0$), and current correction block of Channel 2 is also disabled. The I_{AVG_CS} is the Channel 1 current I_{CS1} . The channel 1 makes any necessary current correction by comparing its channel current (represented by V_{ISET}) with the share bus (V_{ISHARE}). When the share bus does not connect to other ICs, the ISET and ISHARE pins can be shorted together and grounded via a single resistor to ensure zero share error.

Note that the common mode input voltage range of the current sense amplifiers is $V_{CC} - 1.8V$. Therefore, the $r_{DS(ON)}$ sensing should be used for applications with output voltage greater than $V_{CC} - 1.8V$. For example, application of 3.3V output is suggested to use $r_{DS(ON)}$ sensing.

In addition, the R-C network components (for DCR sensing) are selected such that the RC time constant matches the inductor L/DCR time constant. Otherwise, it could cause undershoot/overshoot during load transient and start-up. C is

typically set to 0.1 μ F or higher, while R is calculated with Equation 5.

$$R = \frac{L}{C \cdot DCR} \quad (\text{EQ. 5})$$

Figure 13 shows a simple and flexible configuration for both $r_{DS(ON)}$ and DCR sensing.

Current Share Control in Multiphase Single Output

The I_{AVG_CS} is the average current of both channels (I_{AVG} , 2-phase mode) or only Channel 1 (I_{CS1} , any other modes). ISHARE and ISET pins source a copy of I_{AVG_CS} with 15 μ A offset, for example, the full-scale will be 120 μ A. If one single external resistor is used as R_{ISHARE} connecting the ISHARE bus to ground for all the ICs in parallel, R_{ISHARE} should be set equal to R_{ISET}/N_{CTRL} (where N_{CTRL} is the number of the ISL8120IRZEC controllers in parallel or multiphase operations), and the share bus voltage (V_{ISHARE}) set by the R_{ISHARE} represents the average current of all active channels. Another way to set R_{ISHARE} is to put one resistor in each IC's ISHARE pin and use the same value with R_{ISET} ($R_{ISHARE} = R_{ISET}$), in which case the total equivalent resistance value is also R_{ISET}/N_{CTRL} . The voltage (V_{ISET}) set by R_{ISET} represents the average current of the corresponding device and compared with the share bus (V_{ISHARE}). The current share error signal (I_{CSH_ERR}) is then fed into the current correction block to adjust each channel's PWM pulse accordingly.

The current share function provides at least 10% overall accuracy between ICs, 5% within the IC when using a 1% resistor to sense a 10mV signal. The current share bus works for up to 12-phase.

For multiphase implementation, one single error amplifier should be used for the voltage loop. Therefore, all other

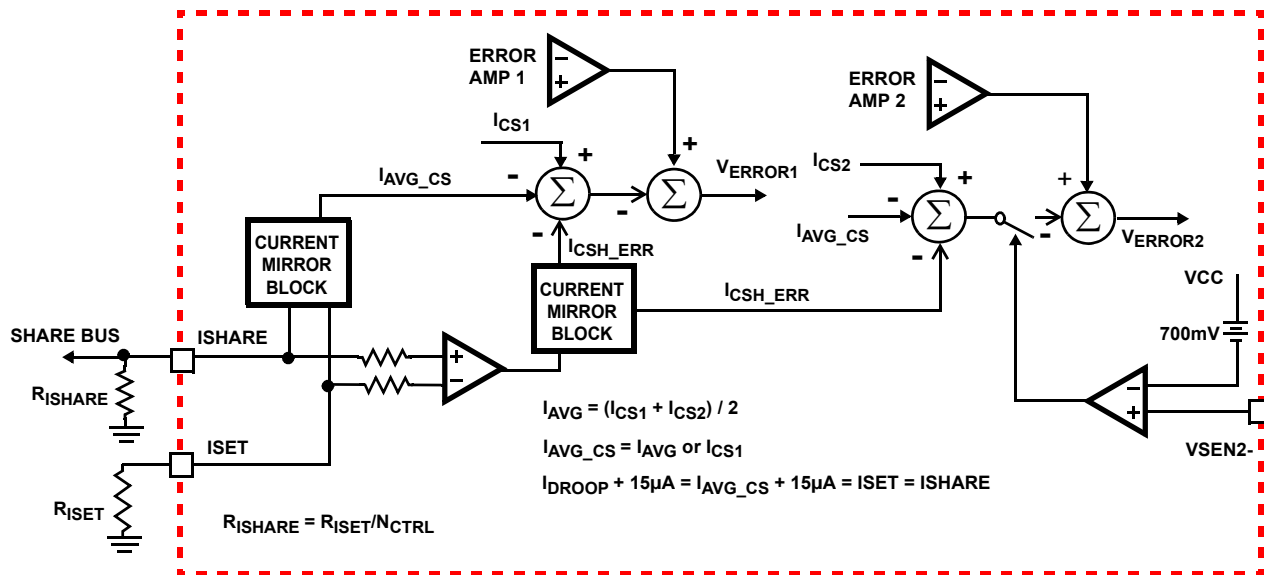

FIGURE 14. SIMPLIFIED CURRENT SHARE AND INTERNAL BALANCE IMPLEMENTATION

channels' error amplifiers should be disabled with their corresponding VSEN- pulled to VCC, as shown in Figure 15.

Current Share Control Loop in Multi-Module with Independent Voltage Loop

The power module controlled by ISL8120IRZEC with its own voltage loop can be paralleled to supply one common output load with its integrated Master-Slave current sharing control, as shown in "Typical Application VIII (Multiple Power Modules in Parallel with Current Sharing Control)" on page 12. A resistor R_{CSR} needs to be inserted between VSEN1- pin and the lower resistor of the voltage sense resistor divider for each module. With this resistor, the correction current sourcing from VSEN1- pin will create a voltage offset to maintain even current sharing among modules. The recommended value for the VSEN1- resistor R_{CSR} is 100Ω and it should not be large in order to keep the unity gain amplifier input pin impedance compatibility. The maximum source current from VSEN1- pin is $350\mu A$, which is combined with R_{CSR} to determine the current sharing regulation range. The generated correction voltage on R_{CSR} is suggested to be within 5% of VREF (0.6V) to avoid fault triggering of UV/OV and PGOOD during dynamic events.

To attain good current balance in system start up preventing single module from overcurrent, the paralleled modules are recommended to be synchronized and the enable pins (EN/FF) should be tied together to initial start-up at the same instant.

Overcurrent Protection

The OCP function is enabled at start-up. When both channels operate independently, the average function is disabled and generates zero average current ($I_{AVG} = 0$). The Channel 2 current (I_{CS2}) is compared with I_{TRIP} ($105\mu A$) and has its own independent overcurrent protection; while the 7 clock cycles delay is bypassed. The Channel 1's current (I_{CS1}) plus $15\mu A$ offset forms a voltage (V_{ISHARE}) with an external resistor R_{ISHARE} and compares with a

precision 1.2V threshold ($\pm 1\%$, 50mV hysteresis); while the $105\mu A$ OCP comparator with 7-cycle delay is also activated.

In multiphase operation, the V_{ISHARE} represents the average current of all active channels and compares with a precision 1.2V threshold ($\pm 1\%$, 50mV hysteresis) to determine the overcurrent condition, while each channel has additional overcurrent trip point at $105\mu A$ with 7-cycle delay. This scheme helps protect against loss of channel(s) in multi-phase mode so that no single channel could carry more than $105\mu A$ in such event. See Figure 13. Note that it is not necessary for the R_{ISHARE} to be scaled to trip at the same level as the $105\mu A$ OCP comparator if the application allows. For instance, when Channel 1 operates independently, the OC trip set by 1.2V comparator can be lower than $105\mu A$ trip point as shown in Equation 6.

$$R_{ISEN1} = \frac{\left(\frac{I_{OC}}{N} + \frac{V_{OUT}}{L} \cdot \left(\frac{1-D}{2F_{SW}} - t_{MIN_OFF} \right) \right) \cdot DCR}{I_{TRIP}} \quad (EQ. 6)$$

$$R_{ISHARE} = \frac{1V}{I_{TRIP}} \quad R_{ISET} = R_{ISHARE} \cdot N_{CNTL}$$

where N is the number of phases; N_{CNTL} is the number of the ISL8120IRZEC controllers in parallel or multiphase operations; $I_{TRIP} = 105\mu A$; I_{OC} is the load overcurrent trip point; t_{MIN_OFF} is the minimum U_{gate} turn off time that is 350ns; R_{ISHARE} in Equation 6 represents the total equivalent resistance in ISHARE pin bus of all ICs in multiphase or module parallel operation.

The overcurrent trip current source is trimmed to $105\mu A \pm 10\%$ for both channels, while the overcurrent threshold (represented by V_{ISHARE}) for multiphase operation (or Channel 1 depending upon configuration) is a precision 1.2V $\pm 1\%$ with 50mV hysteresis.

For the R_{ISEN} chosen for OCP setting, the final value is usually higher than the number calculated from Equation 6.

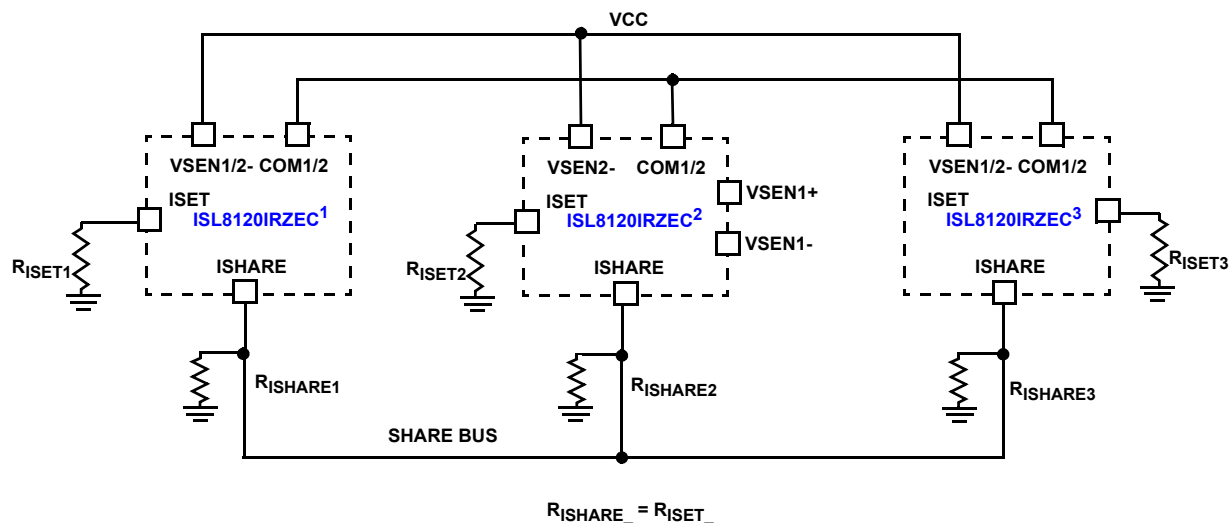

FIGURE 15. SIMPLIFIED 6-PHASE SINGLE OUTPUT IMPLEMENTATION

The reason of which is practical especially for low DCR applications the PCB and inductor pad soldering resistance would have large effects in total impedance affecting the DCR voltage to be sensed.

When OCP is triggered, the controller pulls EN/FF low immediately to turn off UGATE and LGATE. However, if the output overshoot is greater than 113% at EN/FF = LOW, LGATE turns ON until the output voltage drops below 87%.

A delay time, equal to 3 soft-start intervals, is entered to allow the disturbance to clear. After the delay time, the controller then initiates a soft-start interval. If the output voltage comes up and returns to the regulation, PGOOD transitions high. If the OC trip is exceeded during the soft-start interval, the controller pulls EN/VFF low again. The PGOOD signal will remain low and the soft-start interval will be allowed to expire. Another soft-start interval will be initiated after the delay interval. If an overcurrent trip occurs again, this same cycle repeats until the fault is removed.

There is a 100ns delay to prevent any fault triggering during start-up or load transient. For a hard short of the output, the overcurrent protection reduces the regulator RMS output current much less than 60% of the full load current by putting the controller into hiccup mode.

Internal Series Linear and Power Dissipation

The VIN pin is connected to PVCC with an internal series linear regulator (1W Typical), which is internally compensated. The PVCC and VIN pins should have the recommended bypasses connected to GND for proper operation. The internal series linear regulator's input (VIN) can range between 3V to 22V. The internal linear regulator is to provide power for both the internal MOSFET drivers through the PVCC pin and the analog circuitry through the VCC pin. The VCC pin should be connected to the PVCC pin with an RC filter to prevent high frequency driver switching noise from entering the analog circuitry. When VIN drops below 5.0V, the pass element will saturate; PVCC will track VIN, minus the dropout of the linear regulator. When used with an external 5V supply, VIN pin is recommended to be tied directly to PVCC.

FIGURE 16. INTERNAL REGULATOR IMPLEMENTATION

The LDO is capable to supply 250mA with regulated 5.4V output. In 3.3V input applications, when the VIN pin voltage is 3V, the LDO still can supply 150mA while maintaining LDO output voltage higher than VCC falling threshold to keep IC operating. Figure 17 shows the LDO voltage drop under different load current. However, its thermal capability should not be exceeded. The power dissipation inside the IC could be estimated with Equation 7.

FIGURE 17. PVCC vs VIN VOLTAGE

$$P_{IC} = (VIN - PVCC) \cdot I_{VIN} + P_{DR} \quad (EQ. 7)$$

$$I_{VIN} = \left(\frac{Q_{G1} \cdot N_{Q1}}{V_{GS1}} + \frac{Q_{G2} \cdot N_{Q2}}{V_{GS2}} \right) \cdot PVCC \cdot F_{SW} + I_{Q_VIN}$$

$$P_{DR} = P_{DR_UP} + P_{DR_LOW} \quad (\text{EQ. 8})$$

$$P_{DR_UP} = \left(\frac{R_{HI1}}{R_{HI1} + R_{EXT1}} + \frac{R_{LO1}}{R_{LO1} + R_{EXT1}} \right) \cdot \frac{P_{Qg_Q1}}{2}$$

$$P_{DR_LOW} = \left(\frac{R_{HI2}}{R_{HI2} + R_{EXT2}} + \frac{R_{LO2}}{R_{LO2} + R_{EXT2}} \right) \cdot \frac{P_{Qg_Q2}}{2}$$

$$P_{Qg_Q1} = \frac{Q_{G1} \cdot PVCC^2}{V_{GS1}} \cdot F_{SW} \cdot N_{Q1}$$

$$P_{Qg_Q2} = \frac{Q_{G2} \cdot PVCC^2}{V_{GS2}} \cdot F_{SW} \cdot N_{Q2}$$

$$R_{EXT2} = R_{G1} + \frac{R_{GI1}}{N_{Q1}} \quad R_{EXT2} = R_{G2} + \frac{R_{GI2}}{N_{Q2}}$$

where the gate charge (Q_{G1} and Q_{G2}) is defined at a particular gate to source voltage (V_{GS1} and V_{GS2}) in the corresponding MOSFET datasheet; I_{Q_VIN} is the driver's total quiescent current with no load at drive outputs; N_{Q1} and N_{Q2} are number of upper and lower MOSFETs, respectively.

To keep the IC within its operating temperature range, an external power resistor could be used in series with VIN pin to bring the heat out of the IC, or an external LDO could be used when necessary.

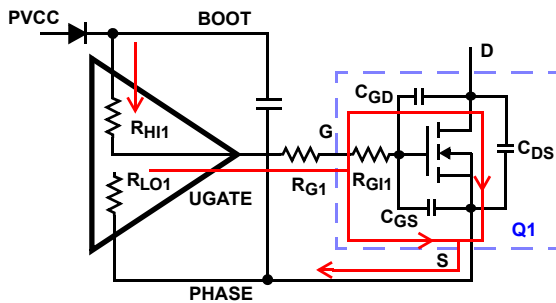

FIGURE 18. TYPICAL UPPER-GATE DRIVE TURN-ON PATH

FIGURE 19. TYPICAL LOWER-GATE DRIVE TURN-ON PATH

Oscillator

The Oscillator is a sawtooth waveform, providing for leading edge modulation with 350ns minimum dead time. The oscillator (Sawtooth) waveform has a DC offset of 1.0V. Each channel's peak-to-peak of the ramp amplitude is set to proportional the voltage applied to its corresponding EN/FF pin. See "Voltage Feed-forward" on page 22.

FIGURE 20. R_{FS} vs SWITCHING FREQUENCY

Frequency Synchronization and Phase Lock Loop

The FSYNC pin has two primary capabilities: fixed frequency operation and synchronized frequency operation. By tying a resistor (R_{FSYNC}) to GND from FSYNC pin, the switching frequency can be set at any frequency between 150kHz and 1.5MHz. Frequency setting curve shown in Figure 20 are provided to assist in selecting the correct value for R_{FSYNC} .

By connecting the FSYNC pin to an external square pulse waveform (such as the CLOCK signal, typically 50% duty cycle from another ISL8120IRZEC), the ISL8120IRZEC will synchronize its switching frequency to the fundamental frequency of the input waveform. The maximum voltage to FSYNC pin is $VCC + 0.3V$. The Frequency Synchronization feature will synchronize the leading edge of CLKOUT signal with the falling edge of Channel 1's PWM clock signal. The CLKOUT is not available until the PLL locks.

The locking time is typically 130μs for $F_{SW} = 500kHz$. EN/VFF1 is released for a soft-start cycle until the FSYNC stabilized and the PLL is in locking. The PLL circuits control only EN/FF1, and control Channel 2's soft-start instead of EN/FF2. Therefore, it is recommended to connect all EN/FF pins together in multiphase configuration.

The loss of a synchronization signal for 13 clock cycles, the IC is disabled until the PLL returns locking, at which point a soft-start cycle is initiated and normal operation resumes. Holding FSYNC low will disable the IC.

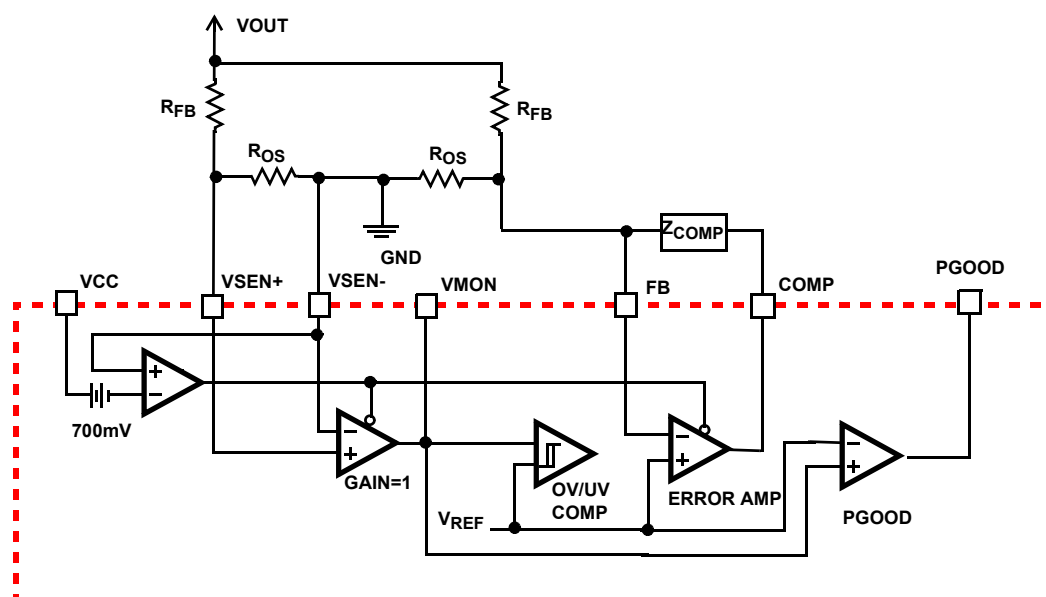

FIGURE 22. DUAL OUTPUT VOLTAGE SENSE FOR SINGLE POINT OF FAILURE PROTECTION

Differential Amplifier for Remote Sense

FIGURE 21. EQUIVALENT DIFFERENTIAL AMPLIFIER

The differential remote sense buffer has a precision unity gain resistor matching network, which has a ultra low offset of 1mV. This true remote sensing scheme helps compensate the droop due to load on the positive and negative rails and maintain the high system accuracy of $\pm 0.6\%$.

The output of the remote sense buffer is connected directly to the internal OV/UV comparator. As a result, a resistor divider should be placed on the input of the buffer for proper regulation, as shown in Figure 24. The VMON pin should be connected to the FB pin by a standard feedback network.

Since the input impedance of VSEN+ pin in respect to VSEN- pin is about 500k Ω , it is highly recommended to include this impedance into calculation and use 100 Ω or less for the lower leg (R_{OS}) of the feedback resistor divider to optimize system accuracy. Note that any RC filter at the inputs of differential amplifier will contribute as a pole to the overall loop compensation.

As some applications will not need the differential remote sense, the output of the remote sense buffer can be disabled and be placed in high impedance by pulling VSEN- within 700mV of VCC. In such an event, the VMON pin can be

used as an additional monitor of the output voltage with a resistor divider to protect the system against single point of failure, which occurs in the system using the same resistor divider for the UV/OV comparator and the output regulation. The resistor divider ratio should be the same as the one for the output regulation so that the correct voltage information is provided to the OV/UV comparator. Figure 22 shows the differential sense amplifier can directly used as a monitor without pulling VSEN- high.

DDR and Dual Mode Operation

If the CLKOUT/REFIN is less than 800mV, an external soft-start ramp (0.6V) can be in parallel with the Channel 2's internal soft-start ramp for DDR/tracking applications (DDR Mode). The output voltage (typical VTT output) of Channel 2 tracks with the input voltage (typical VDDQ*(1 + k) from Channel 1) at the CLKOUT/REFIN pin. As for the external input signal and internal reference signal (ramp and 0.6V), the one with the lowest voltage will be the one to be used as the reference comparing with FB signal. Since the UV/OV comparator uses the same internal reference 0.6V, to guarantee UV/OV and Pre-charged start-up functions of Channel 2, the target voltage derived from Channel 1 (VDDQ) should be scaled close to 0.6V, and it is suggested to be slightly above (+2%) 0.6V with an external resistor divider, which will have the Channel 2 use the internal 0.6V reference after soft-start. Any capacitive load at REFIN pin should not slow down the ramping of this input 150mV lower than the Channel 2 internal ramp. Otherwise, the UV protection could be fault triggered prior to the end of the soft-start. The start-up of Channel 2 can be delayed to avoid such situation happening, if high capacitive load presents at REFIN pin for noise decoupling. During shutdown, Channel 2 will follow Channel 1 until both channels drops below 87%, at which both channels enter UV protection zone. Depending on the

loading, Channel 1 might drop faster than Channel 2. To solve this race condition, Channel 2 can either power up from Channel 1 or bridge the Channel 1 with a high current Schottky diode. If the system requires to shutdown both channels when either has a fault, tying EN/FF1 and EN/FF2 will do the job. In DDR mode, Channel 1 delays 60° over Channel 2.

In Dual mode, depending upon the resistor divider level of REFIN from VCC, the ISL8120IRZEC operates as a dual PWM controller for two independent regulators with a phase shift as shown in Table 2. The phase shift is latched as VCC raises above POR and cannot be changed on-the-fly.

TABLE 2.

MODE	DECODING REFIN RANGE	PHASE for CHANNEL 2 WRT CHANNEL 1	REQUIRED REFIN
DDR	<29% of VCC	-60°	0.6V
Dual	29% to 45% of VCC	0°	37% VCC
Dual	45% to 62% of VCC	90°	53% VCC
Dual	62% to VCC	180°	VCC

Internal Reference and System Accuracy

The internal reference is set to 0.6V. Including bandgap variation and offset of differential and error amplifiers, it has an accuracy of 0.9% over industrial temperature range. While the remote sense is not used, its offset (V_{OS_DA}) should be included in the tolerance calculation. Equations 9 and 10 show the worst case of system accuracy calculation. V_{OS_DA} should

set to zero when the differential amplifier is in the loop, the differential amplifier's input impedance (R_{DIF}) is typically 500k Ω with a tolerance of 20% ($R_{DIF}\%$) and can be neglected when R_{OS} is less than 100 Ω . To set a precision setpoint, R_{OS} can be scaled by two paralleled resistors.

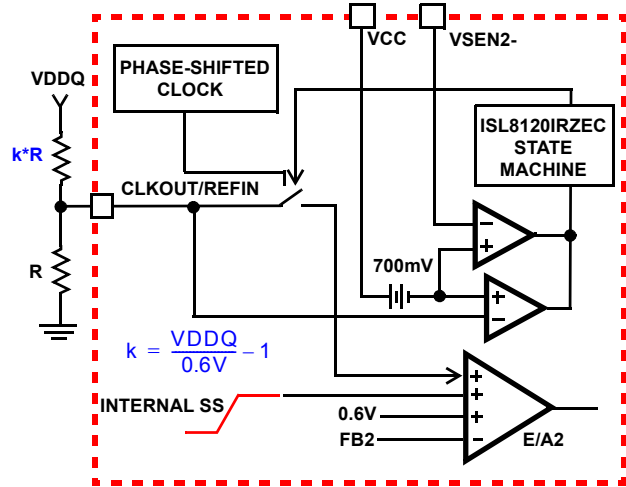

FIGURE 23. SIMPLIFIED DDR IMPLEMENTAION

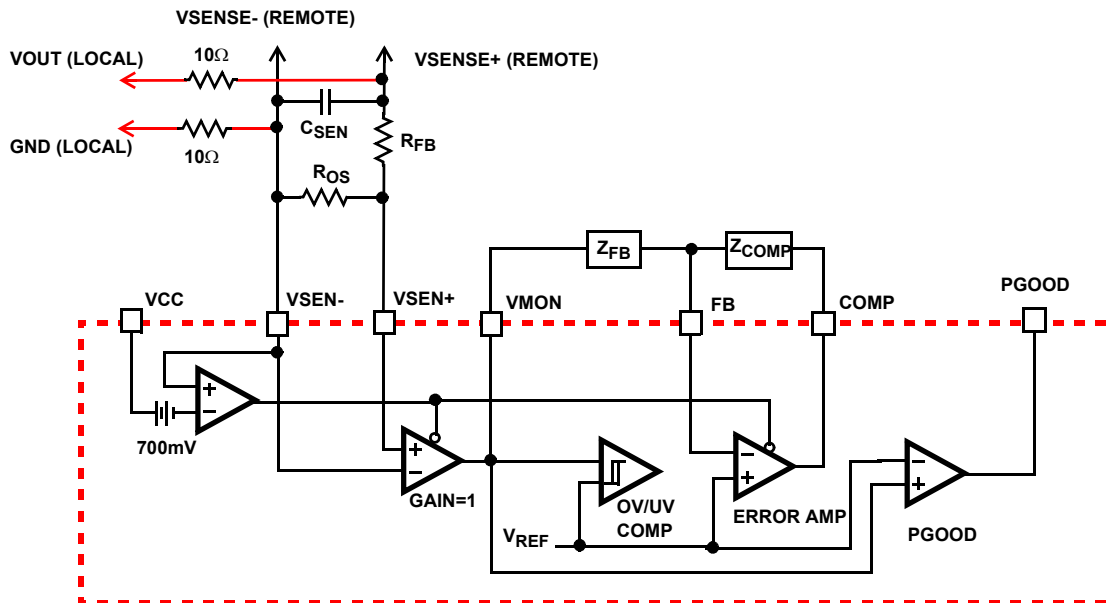

FIGURE 24. SIMPLIFIED REMOTE SENSING IMPLEMENTATION

Figure 25 shows the tolerance of various output voltage regulation for 1%, 0.5%, and 0.1% feedback resistor dividers. Note that the farther the output voltage setpoint away from the internal reference voltage, the larger the tolerance; the lower the resistor tolerance (R%), the tighter the regulation.

$$\%min = (V_{ref} \cdot (1 - Ref\%) - V_{OS_DA}) \cdot \left(1 + \frac{R_{FB} \cdot (1 - R\%)}{R_{OSMAX}} \right) \quad (EQ. 9)$$

$$R_{OSMAX} = \frac{1}{\frac{1}{R_{OS} \cdot (1 + R\%)} + \frac{1}{R_{DIF} \cdot (1 + R_{DIF}\%)}}$$

$$\%max = (V_{ref} \cdot (1 - Ref\%) - V_{OS_DA}) \cdot \left(1 + \frac{R_{FB} \cdot (1 - R\%)}{R_{OSMIN}} \right) \quad (EQ. 10)$$

$$R_{OSMIN} = \frac{1}{\frac{1}{R_{OS} \cdot (1 - R\%)} + \frac{1}{R_{DIF} \cdot (1 - R_{DIF}\%)}}$$
