

## ISL8501

Triple Output Controller with 1A Standard Buck PWM and Dual LDOs

FN6500  
 Rev 1.00  
 July 12, 2007

The ISL8501 is a high-performance, triple output controller that provides a single, high frequency power solution for a variety of point of load applications. The ISL8501 integrates a 1A standard buck PWM controller and switching MOSFET with two 500mA LDOs.

The PWM controller in the ISL8501 drives an internal switching N-Channel power MOSFET and requires an external Schottky diode to generate an output voltage from 0.6V to 20V. The integrated power switch is optimized for excellent thermal performance up to 1A of output current. The standard buck input voltage range supports a fixed 5V or variable 6V to 25V range. The PWM regulator switches at a fixed frequency of 500kHz and utilizes simple voltage mode control with input voltage feed forward to provide flexibility in component selection and minimize solution size. Protection features include overcurrent, undervoltage, and thermal overload protection integrated into the IC. The ISL8501 power good signal output indicates loss of regulation on the PWM output.

The ISL8501 features two adjustable LDO regulators using internal PMOS transistors as pass devices. Separate enable pins (EN\_LDO1, EN\_LDO2) control each LDO output. A single power good signal output indicates loss of regulation on either of the two LDO outputs. Independent overcurrent and thermal fault shutdown monitors are integrated into the LDO section.

ISL8501 is available in a small 4mmx4mm Quad Flat No-Lead (QFN) package.

### Ordering Information

PART NUMBER (Note)	PART MARKING	TEMP. RANGE (°C)	PACKAGE (Pb-free)	PKG. DWG. #
ISL8501IRZ*	85 01IRZ	-40 to +85	24 Ld 4x4 QFN	L24.4x4D

\*Add "-T" suffix for tape and reel

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

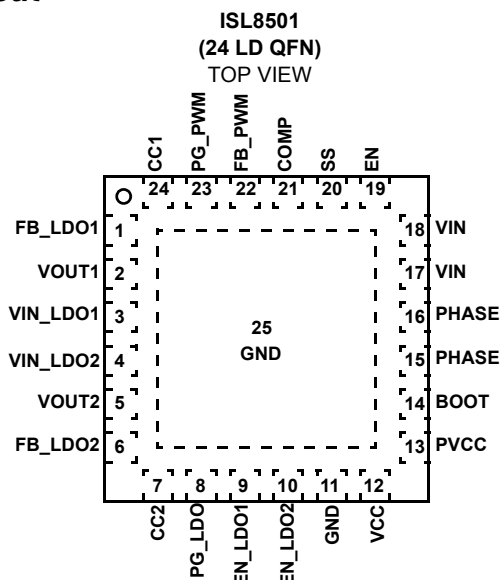

### Features

- Standard Buck Controller with Integrated Switching Power MOSFET and Dual LDOs
- Integrated Boot Diode
- Input Voltage Range
  - Fixed 5V  $\pm 10\%$
  - Variable 6V to 25V
- PWM Output Voltage Adjustable from 0.6V to 20V with Continuous Output Current up to 1A
- Voltage Mode Control with Voltage Feed Forward
- Fixed 500kHz Switching Frequency
- Externally Adjustable Soft-Start Time
- Output Undervoltage Protection
- Dual LDO Adjustable Options
  - LDO1, 0.6V to 4.2V ..... 500mA
  - LDO2, 0.6V to 4.2V ..... 500mA
- Individual Enable Inputs
- Two PGOOD Outputs (PWM and both LDOs)
- Overcurrent Protection
- Thermal Overload Protection
- Internal 5V LDO regulator
- Pb-Free Plus Anneal Available (RoHS Compliant)

### Applications

- General Purpose
- WLAN Cards-PCMCIA, Cardbus32, MiniPCI Cards-Compact Flash Cards
- Hand-Held Instruments

### Pinout

## Typical Application Schematics

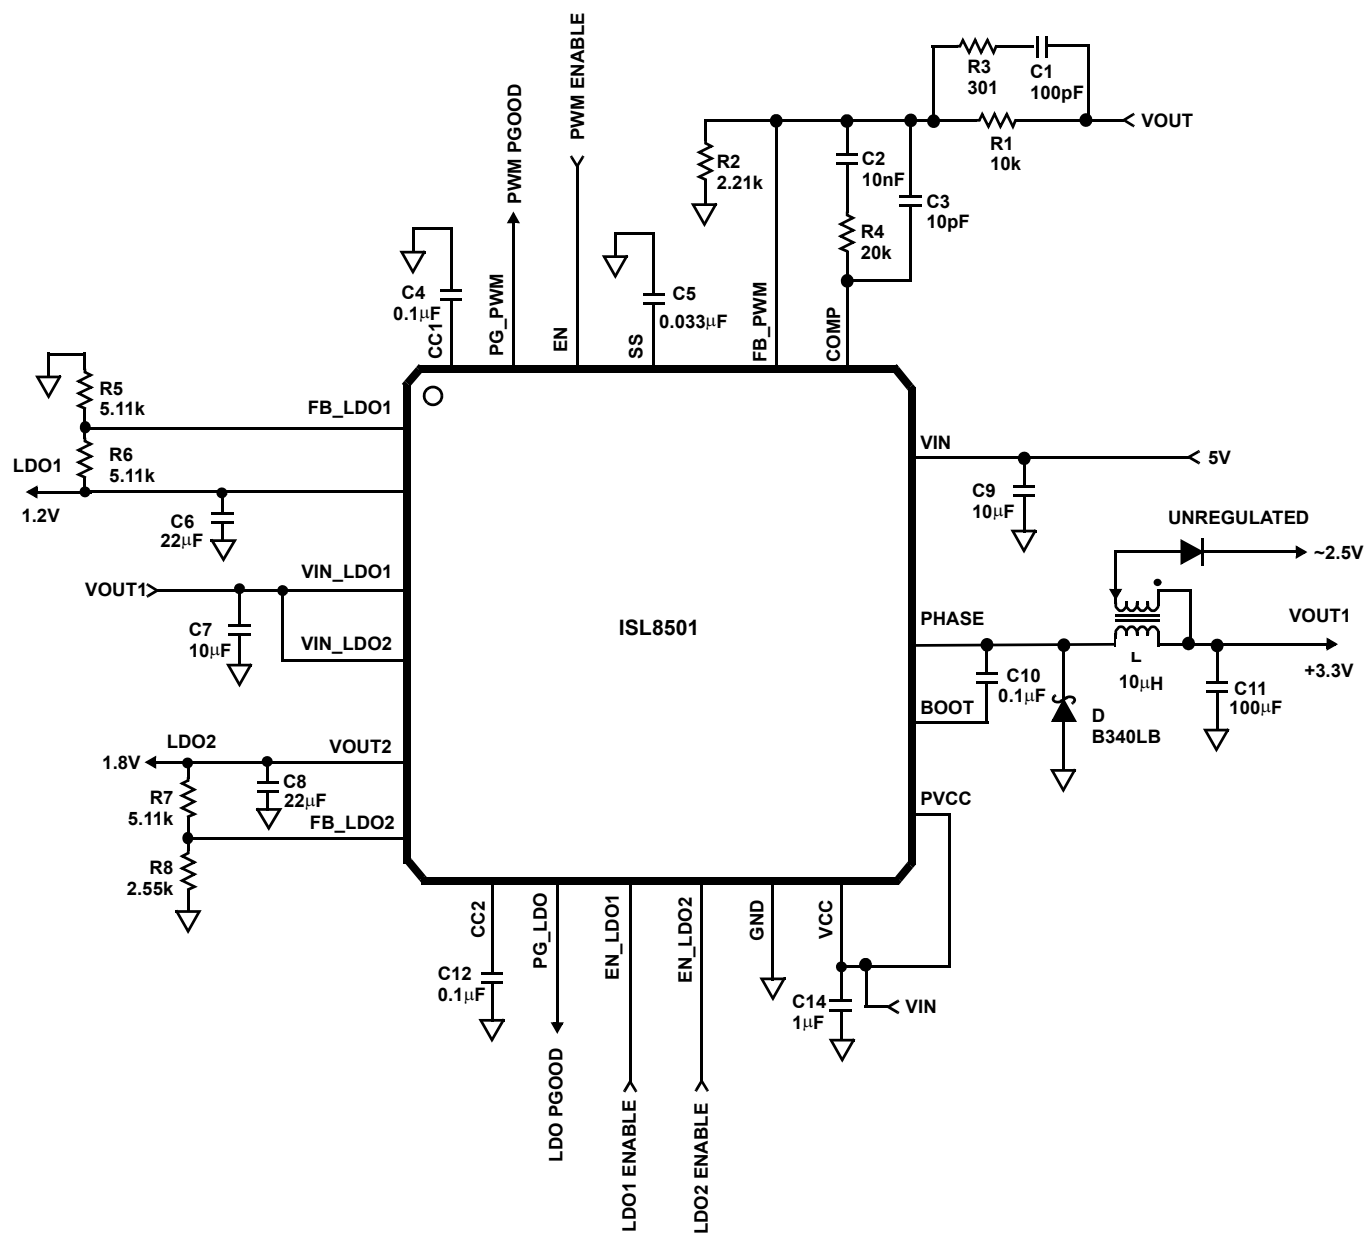

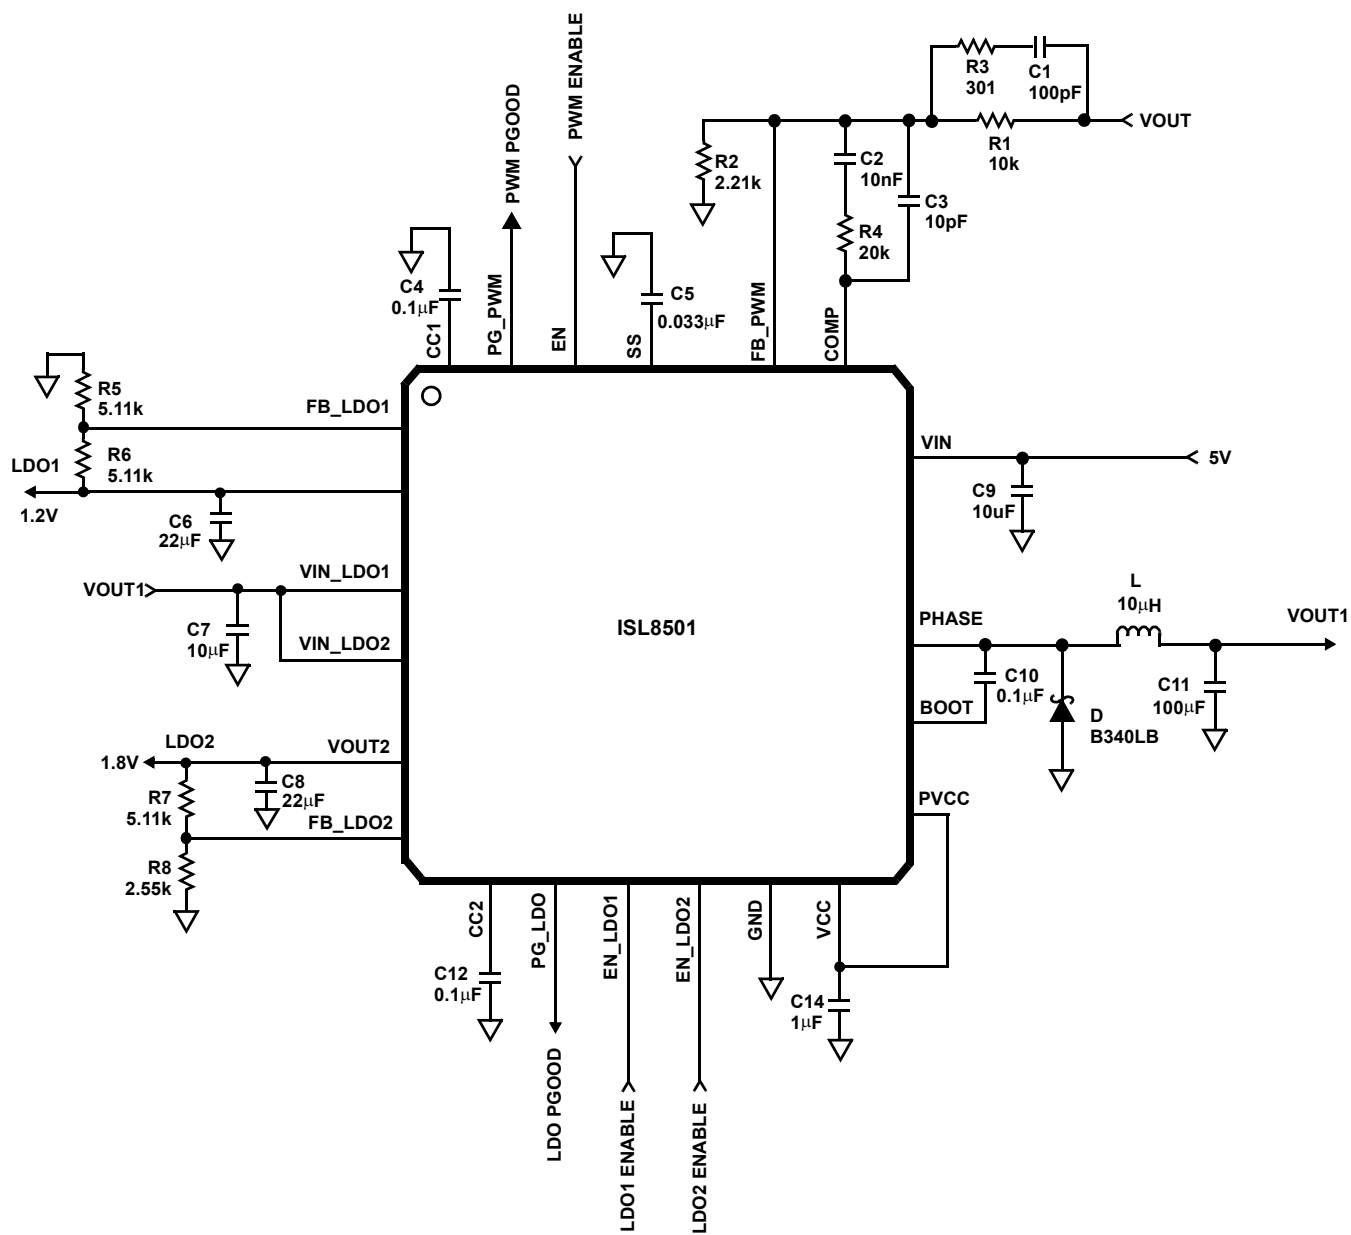

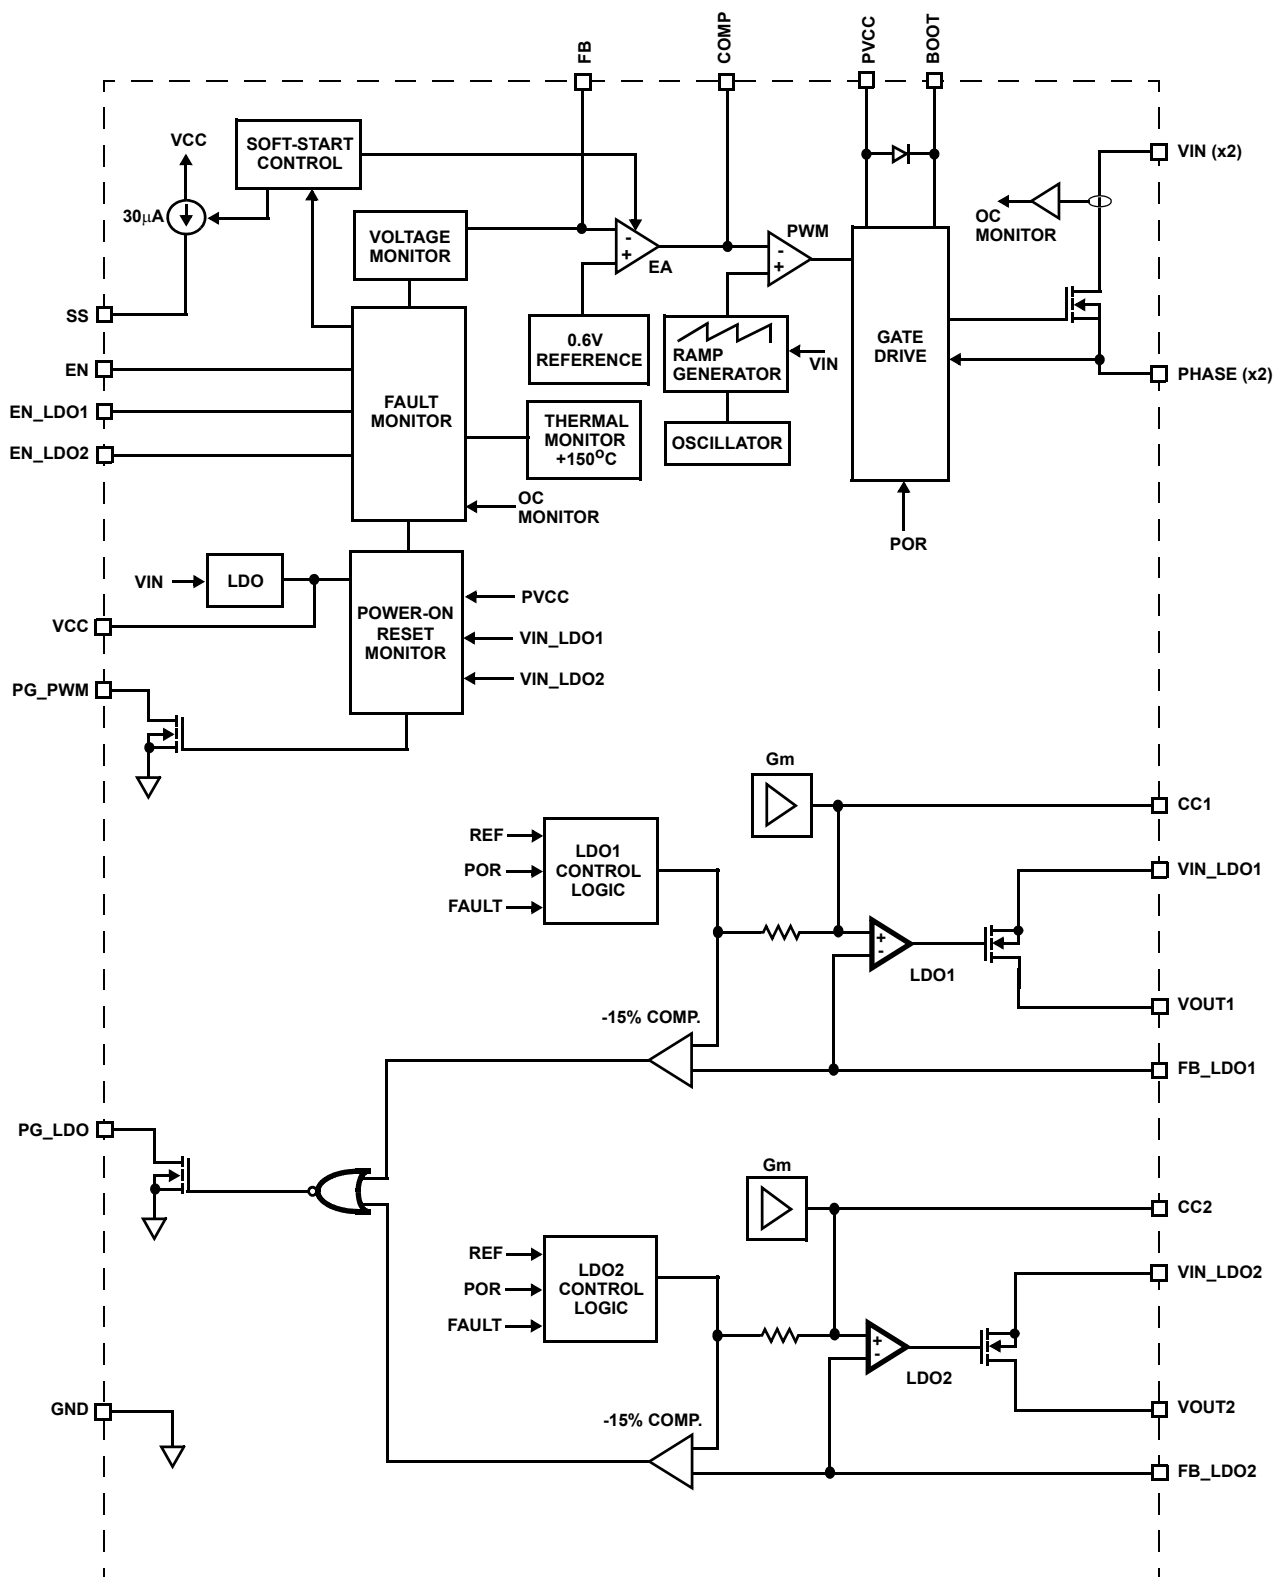

FIGURE 1. VIN RANGE FROM 4.5V TO 5.5V

# Typical Application Schematics (Continued)

FIGURE 2.  $V_{IN}$  RANGE FROM 6V TO 25V

## Functional Block Diagram

**Absolute Maximum Ratings** (Note 1)

VIN to GND	-0.3V to +26V
VIN_LDOx to GND	-0.3V to +6V
BOOT to GND	-0.3V to +33V
PHASE to BOOT	-6V to +0.3V
VCC to GND	-0.3V to +6V
VOUT, LDO1, LDO2 to GND	-0.3V to +6V
FB_PWM, FB_LDOx to GND	-0.3V to +6V
PG_PWM, PG_LDOx to GND	-0.3V to +6V
EN, EN_LDOx to GND	-0.3V to +6V
CC1, CC2 to GND	-0.3V to +6V
VCC Output Current	50mA

**Thermal Information**

Thermal Resistance	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)
QFN Package (Notes 1, 2)	36	5
Maximum Junction Temperature (Plastic Package)	+150°C	
Maximum Storage Temperature Range	-65°C to +150°C	
Junction Temperature Range	-55°C to +150°C	
Storage Temperature Range	-65°C to +150°C	
Operating Temperature Range	-40°C to +85°C	
Pb-free reflow profile	see link below	
<a href="http://www.intersil.com/pbfree/Pb-FreeReflow.asp">http://www.intersil.com/pbfree/Pb-FreeReflow.asp</a>		

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

\*An accidental short between VCC and GND may cause excessive heating and permanent damage to the device.

**NOTES:**

1.  $\theta_{JA}$  is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379 for details.
2. For  $\theta_{JC}$ , the "case temp" location is the center of the exposed metal pad on the package underside. See Tech Brief TB379 for details.

**Electrical Specifications**

Unless Otherwise Noted, All Parameter Limits are Guaranteed Over the Recommended Operating Conditions and the Typical Specifications are Measured at the Following Conditions:  $T_A = -40^\circ\text{C}$  to  $+85^\circ\text{C}$  (Note 7),  $V_{IN} = 6\text{V}$  to  $25\text{V}$ , Unless Otherwise Noted. Typical Values are at  $T_A = +25^\circ\text{C}$ .

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNITS

**NOTES:**

- Test Condition:  $V_{IN} = 15\text{V}$ , FB forced above regulation point (0.6V), no switching, and power MOSFET gate charging current not included.
- Limits established by characterization and are not production tested.
- The dropout voltage is defined as minimum amount VIN must exceed a desired VOUT operating point.  $V_{LDO} = V_{IN\_LDO} - V_{OUT}$ .
- The input voltage VCC must be higher than VIN\_LDO or the LDO will not function.
- Specifications at  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  are guaranteed by  $+25^{\circ}\text{C}$  test with margin limits.

## Pin Descriptions

### VIN

The input supply for the PWM regulator power stage and the source for the internal linear regulator that provides bias for the IC. Place a ceramic capacitor from VIN to GND, close to the IC for decoupling (typical 1 $\mu$ F).

### PVCC

Connect this pin to VCC.

### GND

Ground connect for the IC and thermal relief for the package. The exposed pad must be connected to GND and soldered to the PCB. All voltage levels are measured with respect to this pin.

### VCC

Internal 5V linear regulator output provides bias to all the internal control logic. The ISL8501 may be powered directly from a 5V ( $\pm 10\%$ ) supply at this pin. When used as a 5V supply input, this pin must be externally connected to VIN. The VCC pin must always be decoupled to GND with a ceramic bypass capacitor (minimum 1 $\mu$ F) located close to the pin.

TABLE 1. INPUT SUPPLY CONFIGURATION

INPUT	PIN CONFIGURATION
6V to 25V	Connect the input supply to the VIN pin only. The VCC pin will provide a 5V output from the internal linear regulator.
5V $\pm 10\%$	Connect the input supply to the VIN and VCC pins.

### FB and COMP

The standard buck regulator employs a single voltage control loop. FB is the negative input to the voltage loop error amplifier. COMP is the output of the error amplifier. The output voltage is set by an external resistor divider connected to FB. With a properly selected divider, the output voltage can be set to any voltage between the power rail (reduced by converter losses) and the 0.6V reference. Connecting an AC network across COMP and FB provide loop compensation to the amplifier.

In addition, the PWM regulator power good and under-voltage protection circuitry use FB to monitor the regulator output voltage.

### PHASE

Switch node connections to internal power MOSFET source, external output inductor, and external diode cathode.

### BOOT

Floating bootstrap supply pin for the power MOSFET gate driver. The bootstrap capacitor provides the necessary charge to turn and hold on the internal N-Channel MOSFET. Connect an external capacitor from this pin to PHASE.

### EN

PWM controller enable input. The PWM converter and LDO's outputs are held off when the pin is pulled to ground. When the voltage on this pin rises above 1.7V, the chip is enabled.

### SS

Program pin for soft-start duration. A regulated 30 $\mu$ A pull-up current source charges a capacitor connected from the pin to GND. The output voltage of the converter follows the ramping voltage on the SS pin.

### VIN\_LDO1, VIN\_LDO2

Input voltage pin for each LDO.

### VOUT1, VOUT2

LDO output pins. Bypass with a minimum of 2.2 $\mu$ F, low ESR capacitor to GND for stable operation.

### FB\_LDO1, FB\_LDO2

Used to set the output of LDO with the proper selection of resistor divider. The resistors should be selected to provide a minimum current of 200nA load for the LDO.

### CC1, CC2

Compensation capacitor connection for each LDO. Connect a 0.033 $\mu$ F capacitor from each pin to ground.

### EN\_LDO1, EN\_LDO2

These pins are threshold-sensitive enable inputs for the individual LDOs. Held low, this pin disables the respective LDO.

### PG\_PWM

PWM converter power good output. Open drain logic output that is pulled to ground when the output voltage is outside regulation limits. Connect a 100k $\Omega$  resistor from this pin to VCC. Pin is low when the buck regulator output voltage is not within 10% of the respective nominal voltage, or during the soft-start interval. Pin is high impedance when the output is within regulation.

### PG\_LDO

Combined LDO power good output. Connect a 100k $\Omega$  resistor from this pin to VCC.

## Typical Performance Curves

## Detailed Description

The ISL8501 combines a standard buck PWM controller with an integrated switching MOSFET and two low dropout (LDO) linear regulators with internal pass devices. The buck controller drives an internal N-Channel MOSFET and requires an external diode to deliver load current up to 1A. A Schottky diode is recommended for improved efficiency and performance over a standard diode. The standard buck regulator can operate from either an unregulated DC source, such as a battery, with a voltage ranging from +6.0V to +25V, or from a regulated system rail of +5V. When operating from +6V or greater, the controller is biased from an internal +5V LDO voltage regulator. The converter output is regulated down to 0.6V from either input source. Each LDO linear regulator can source up to 500mA continuous output current with +2V or greater input supply and +1.0V or higher output voltage. These features make the ISL8501 ideally suited for FPGA and wireless chipset power applications.

The PWM control loop uses a single output voltage loop with input voltage feed forward which simplifies feedback loop compensation and rejects input voltage variation. External feedback loop compensation allows flexibility in output filter component selection. The regulator switches at a fixed 500kHz.

The buck regulator and LDOs are provided with independent current limits. The current limit in the buck regulator is achieved by monitoring the drain-to-source voltage drop of the internal switching power MOSFET. The current limit threshold is internally set at 2A. The part also features undervoltage protection by latching the switching MOSFET driver to the OFF state during an overcurrent, when the output voltage is lower than 70% of the regulated output. This helps minimize power dissipation during a short-circuit condition. Due to only the switching power MOSFET integration, there is no overvoltage protection feature for this part.

The ISL8501 monitors and controls the pass transistor's gate voltage to limit the output current. The current limits for both LDOs is 800mA typical. Neither LDO has overvoltage or undervoltage protection. When the current limit in either output is reached, the output no longer regulates the voltage, but regulates the current to the value of the current limit.

### +5V Internal Bias Supply (VCC)

Voltage applied to the VIN pin with respect to GND is regulated to +5V DC by an internal LDO regulator. The output of the LDO, VCC, is the bias voltage used by all the internal control and protection circuitry. The VCC pin requires a ceramic capacitor connected to GND. The capacitor serves to stabilize the LDO and to decouple load transients.

The input voltage range for the ISL8501 is specified as +6V to +25V or +5V  $\pm 10\%$ . In the case of an unregulated supply case, the power supply is connected to VIN only. Once

enabled, the linear regulator will turn-on and rise to +5V on VCC. In the +5V supply case, the VCC and VIN pins must be tied together to bypass the LDO. The external decoupling capacitor is still required in this mode. Do not short VCC to GND.

## Operation Initialization

The power-on reset circuitry and enable inputs prevent false startup of the PWM regulator and LDO outputs. Once all the input criteria are met, the controller soft-starts the output voltage to the programmed level.

### Power-On Reset and Undervoltage Lockout

The PWM portion of the ISL8501 automatically initializes upon receipt of input power. The power-on reset (POR) function continually monitors the VCC and PVCC voltages. While both are below their POR thresholds, the controller inhibits switching of the internal power MOSFET. Once exceeded, the controller initializes the internal soft-start circuitry. If either input supply drops below their falling POR threshold during soft-start or operation, the buck regulator latches off.

Independent LDO supply inputs (VIN\_LDO1 and VIN\_LDO2) allow flexibility in partitioning linear regulator power. Power supplies connected to either LDO supply input must exceed the undervoltage lockout (UVLO) threshold before that LDO is initialized. If the input supply drops below the falling UVLO threshold during operation, the low dropout voltage regulator latches off.

### Enable and Disable

All internal power devices are held in a high-impedance state, which ensures they remain off while in shutdown mode. Typically the enable input for a specific output is toggled high after the input supply to that regulator is active and the internal LDO has exceeded its POR threshold.

The EN pin enables the buck controller portion of the ISL8501. When the voltage on the EN pin exceeds the POR rising threshold, the controller initiates the soft-start function for the PWM regulator. If the voltage on the EN pin drops below the POR falling threshold, the buck regulator shuts down.

Individual LDO enable inputs (EN\_LDO1 and EN\_LDO2) allow independent control of each regulator. Make sure EN is on, when the voltage on either pin exceeds the POR rising threshold, linear regulator operation is initiated for that controller. If the voltage then drops below the hysteresis level for the enable pin, the LDO shuts down.

Pulling the EN low simultaneously puts all outputs into shutdown mode, and supply current drops to 10 $\mu$ A typical.

### Soft-Start

Once the input supply latch and enable threshold are met, the soft-start function is initialized. The soft-start circuitry begins sourcing 30 $\mu$ A, from an internal current source, which

charges the external soft-start capacitor. The voltage on SS begins ramping linearly from ground until the voltage across the soft-start capacitor reaches 3.0V. This linear ramp is applied to the non-inverting input of the internal error amplifier and overrides the nominal 0.6V reference. The output voltage reaches its regulation value when the soft-start capacitor voltage reaches 1.6V. Connect a capacitor from SS pin to ground. This capacitor, along with an internal 30μA current source sets the soft-start interval of the converter,  $t_{SS}$ .

$$C_{SS}[\mu F] = 50 \cdot t_{SS}[S] \quad (EQ. 1)$$

Upon disable, SS pin voltage will discharge to zero voltage.

### Power Good

PG\_PWM is an open-drain output of a window comparator that continuously monitors the buck regulator output voltage. PG\_PWM is actively held low when EN is low and during the buck regulator soft-start period. After the soft-start period terminates, PG\_PWM becomes high impedance as long as the output voltage is within  $\pm 10\%$  of the nominal regulation voltage set by FB\_PWM. When VOUT drops 10% below or rises 10% above the nominal regulation voltage, the ISL8501 pulls PG\_PWM low. Any fault condition forces PG\_PWM low until the fault condition is cleared by attempts to soft-start. For logic level output voltages, connect an external pull-up resistor between PG\_PWM and VCC. A 100k resistor works well in most applications. Note that the PG\_PWM window detector is completely independent of the undervoltage protection fault detectors and the state of LDO1 and LDO2 outputs.

PG\_LDO is an open drain pull-down NMOS output that will sink 1mA at 0.3V max. PG\_LDO monitors both LDO1 and LDO2 output. It goes to the active low state if either LDO output is below regulation by a value greater than 15%. When the one of the LDO is disabled, the PG\_LDO switch to only monitor the active LDO output.

### Output Voltage Selection

All three regulator output voltages can be programmed using external resistor dividers that scale the voltage feedback relative to the internal reference voltage. The scaled voltage is fed back to the inverting input of the error amplifier. Refer to Figure 3.

The output voltage programming resistor,  $R_2$ , will depend on the value chosen for the feedback resistor,  $R_1$ , and the desired output voltage,  $V_{OUT}$ , of the regulator. See Equation 1. The value for the feedback resistor is typically between 1kΩ and 10kΩ.

$$R_2 = \frac{R_1 \cdot 0.6V}{V_{OUT} - 0.6V} \quad (EQ. 2)$$

If the output voltage desired is 0.6V, then  $R_2$  is left unpopulated.

FIGURE 31. EXTERNAL RESISTOR DIVIDER

The buck output can be program as high as 20V. Proper heatsinking must be provided to insure that the junction temperature do not exceed +125°C.

When the output is set greater than 3.6V, it is recommended to pre-load at least 1mA and make sure that the input rise time is >> faster than the VOUT1 rise time. This allows the BOOT capacitor adequate time to charge for proper operation.

### Protection Features

The ISL8501 limits current in all on-chip power devices to limit on-chip power dissipation. Overcurrent limits on all three regulators protect internal power devices from excessive thermal damage. Undervoltage protection circuitry on the buck regulator provides a second layer of protection for the internal power device under high current conditions.

### Buck Regulator Overcurrent Protection

During the PWM on-time, the current through the internal switching MOSFET is sampled and scaled through an internal pilot device. The sampled current is compared to a nominal 2A overcurrent limit. If the sampled current exceeds the overcurrent limit reference level, an internal overcurrent fault counter is set to 1 and an internal flag is set. The internal power MOSFET is immediately turned off and will not be turned on again until the next switching cycle.

The protection circuitry continues to monitor the current and turns off the internal MOSFET as described. If the over-current condition persists for four sequential clock cycles, the over-current fault counter overflows indicating an overcurrent fault condition exists. The regulator is shut down and power good goes low. If the overcurrent condition clears prior to the counter reaching four consecutive cycles, the internal flag and counter are reset.

The protection circuitry attempts to recover from the overcurrent condition after waiting 4 soft-start cycles. The internal overcurrent flag and counter are reset. A normal soft-start cycle is attempted and normal operation continues if the fault condition has cleared. If the overcurrent fault counter overflows during soft-start, the converter shuts down and this hiccup mode operation repeats.

### **LDO Current Limit**

The ISL8501 monitors and controls the pass transistor's gate voltage to limit output current. The current limit for both LDO1 and LDO2 is 700mA typical. The output can be shorted to ground without damaging the part due to the current limit and thermal protection features.

### **Undervoltage Protection**

If the voltage detected on the buck regulator FB pin falls 15% below the internal reference voltage, the undervoltage fault condition flag is set. The fault protection circuitry checks the overcurrent flag. If the overcurrent flag is set, the fault monitor latches off the internal power MOSFET. The regulator will not restart until either a POR restart or the EN pin is cycled.

If the overcurrent flag is not set, an internal undervoltage counter is set to 1. The fault controller continues to monitor the FB pin for 4 clock cycles. If the fault condition persists, the regulator is shutdown. The controller enters a recovery mode similar to the overcurrent hiccup mode. No action is taken for 4 soft-start cycles and the internal undervoltage counter and fault condition flag are reset. A normal soft-start cycle is attempted and normal operation continues if the fault condition has cleared. If the undervoltage counter overflows during soft-start, the converter is shut down and this hiccup mode operation repeats.

Under-voltage protection only applies to the buck regulator output, the two LDO outputs do not have undervoltage protection.

### **Thermal Overload Protection**

Thermal overload protection limits total power dissipation in the ISL8501. There are three sensors on the chip to monitor the junction temperature of the internal LDO, PWM switching power N-Channel MOSFET, and LDO pass transistors. When the junction temperature ( $T_J$ ) of any of the three sensors exceeds +150°C, the thermal sensor sends a signal to the fault monitor.

The fault monitor commands the buck regulator to shut down and the LDOs to turn off their pass transistors. The buck regulator soft-starts and the LDO pass transistors turn on again after the IC's junction temperature cools by +20°C. The buck regulator experiences hiccup mode operation and the LDOs a pulsed output during continuous thermal overload conditions. For continuous operation, do not exceed the +125°C junction temperature rating.

### **Low Dropout Regulators**

Each regulator consists of a 0.6V reference, error amplifier, MOSFET driver, P-Channel pass transistor, and dual-mode comparator. The voltage is set by means of an external resistor divider on the FB\_LDOx pins. The 0.6V band gap reference is connected to the error amplifier's inverting input. The error amplifier compares this reference to the selected feedback voltage and amplifies the difference. The MOSFET

driver reads the error signal and applies the appropriate drive to the P-Channel pass transistor. If the feedback voltage is lower than the reference voltage, the pass transistor gate is pulled lower, allowing more current to pass and increasing the output voltage. If the feedback voltage is higher than the reference voltage, the pass transistor gate is driven higher, allowing less current to pass to the output.

### **Internal P-Channel Pass Transistor**

Both the LDO regulators in the ISL8501 feature a typical  $0.33\Omega$   $r_{DS(ON)}$  P-Channel MOSFET pass transistor. This provides several advantages over similar designs using PNP bipolar pass transistors. The P-Channel MOSFET requires no base drive, which reduces quiescent current considerably. PNP based regulators waste considerable current in dropout when the pass transistor saturates. They also use high base drive currents under large loads. The ISL8501 does not have these drawbacks.

### **Integrator Circuitry**

The ISL8501 uses external compensation capacitors for minimizing load and line regulation errors and for lowering output noise. When the output voltage shifts due to varying load current or input voltage, the integrator capacitor voltage is raised or lowered to compensate for the systematic offset at the error amplifier. Compensation is limited to  $\pm 5\%$  to minimize transient overshoot when the device goes out of dropout, current limit, or thermal shutdown. Place a 33nF capacitor to GND from CC1 and CC2.

## **Application Guidelines**

### **Operating Frequency**

The ISL8501 operates at a fixed switching frequency of 500kHz.

### **LDO Regulator Capacitor Selection**

Capacitors are required at the ISL8501 LDO Regulators' input and output for stable operation over the entire load range and the full temperature range. Use  $>1\mu\text{F}$  capacitor at the input of LDO Regulators, VIN\_LDO pins. The input capacitor lowers the source impedance of the input supply. Larger capacitor values and lower ESR provides better PSRR and line transient response. The input capacitor must be located at a distance of not more than 0.5 inches from the VIN\_LDO pins of the IC and returned to a clean analog ground. Any good quality ceramic capacitor can be used as an input capacitor.

The output capacitors used in LDO regulators are used to provide dynamic load current. The amount of capacitance and type of capacitor should be chosen with this criteria in mind. The output capacitor selected must meet the requirements of minimum amount of capacitance and ESR for both LDOs. The ISL8501 is specifically designed to work with small ceramic output capacitors. The output capacitor's ESR affects stability and output noise. Use an output capacitor with an ESR of 50m $\Omega$  or less to insure stability and

optimum transient response. For stable operation, a ceramic capacitor, with a minimum value of 10µF, is recommended for both LDO outputs. There is no upper limit to the output capacitor value. Larger capacitor can reduce noise and improve load transient response, stability and PSRR. The output capacitor should be located very close to V<sub>OUT</sub> pins to minimize impact of PC board inductances and the other end of the capacitor should be returned to a clean analog ground.

### **Buck Regulator Output Capacitor Selection**

An output capacitor is required to filter the inductor current and supply the load transient current. The filtering requirements are a function of the switching frequency and the ripple current. The load transient requirements are a function of the slew rate (di/dt) and the magnitude of the transient load current. These requirements are generally met with a mix of capacitors and careful layout.

Embedded processor systems are capable of producing transient load rates above 1A/ns. High frequency capacitors initially supply the transient and slow the current load rate seen by the bulk capacitors. The bulk filter capacitor values are generally determined by the ESR (Effective Series Resistance) and voltage rating requirements, rather than actual capacitance requirements.

High frequency decoupling capacitors should be placed as close to the power pins of the load as physically possible. Be careful not to add inductance in the circuit board wiring that could cancel the usefulness of these low inductance components. Consult with the manufacturer of the load on specific decoupling requirements.

Use only specialized low-ESR capacitors intended for switching-regulator applications for the bulk capacitors. The bulk capacitor's ESR will determine the output ripple voltage and the initial voltage drop after a high slew-rate transient. An aluminum electrolytic capacitor's ESR value is related to the case size with lower ESR available in larger case sizes. However, the Equivalent Series Inductance (ESL) of these capacitors increases with case size and can reduce the usefulness of the capacitor to high slew-rate transient loading. Unfortunately, ESL is not a specified parameter. Work with your capacitor supplier and measure the capacitor's impedance with frequency to select a suitable component. In most cases, multiple electrolytic capacitors of small case size perform better than a single large case capacitor.

### **Output Inductor Selection**

The output inductor is selected to meet the output voltage ripple requirements and minimize the converter's response time to the load transient. The inductor value determines the converter's ripple current and the ripple voltage is a function of the ripple current. The ripple voltage and current are approximated by the following equations:

$$\Delta I = \frac{V_{IN} - V_{OUT}}{F_s \times L} \times \frac{V_{OUT}}{V_{IN}} \quad \Delta V_{OUT} = \Delta I \times ESR \quad (EQ. 3)$$

Increasing the value of inductance reduces the ripple current and voltage. However, the large inductance values reduce the converter's response time to a load transient. The recommended  $\Delta I$  is 30% of the maximum output current.

One of the parameters limiting the converter's response to a load transient is the time required to change the inductor current. Given a sufficiently fast control loop design, the ISL8501 will provide either 0% or 100% duty cycle in response to a load transient. The response time is the time required to slew the inductor current from an initial current value to the transient current level. During this interval the difference between the inductor current and the transient current level must be supplied by the output capacitor. Minimizing the response time can minimize the output capacitance required.

The response time to a transient is different for the application of load and the removal of load. The following equations give the approximate response time interval for application and removal of a transient load:

$$t_{RISE} = \frac{L \times I_{TRAN}}{V_{IN} - V_{OUT}} \quad t_{FALL} = \frac{L \times I_{TRAN}}{V_{OUT}} \quad (EQ. 4)$$

where:  $I_{TRAN}$  is the transient load current step,  $t_{RISE}$  is the response time to the application of load, and  $t_{FALL}$  is the response time to the removal of load. The worst case response time can be either at the application or removal of load. Be sure to check both of these equations at the minimum and maximum output levels for the worst case response time.

### **Rectifier Selection**

Current circulates from ground to the junction of the MOSFET and the inductor when the high-side switch is off. As a consequence, the polarity of the switching node is negative with respect to ground. This voltage is approximately -0.5V (a Schottky diode drop) during the off time. The rectifier's rated reverse breakdown voltage must be at least equal to the maximum input voltage, preferably with a 20% derating factor. The power dissipation is:

$$P_D[W] = I_{OUT} \cdot V_D \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (EQ. 5)$$

where  $V_D$  is the voltage of the Schottky diode = 0.5V to 0.7V

### **Input Capacitor Selection**

Use a mix of input bypass capacitors to control the voltage overshoot across the MOSFETs. Use small ceramic capacitors for high frequency decoupling and bulk capacitors to supply the current needed each time the switching MOSFET turns on. Place the small ceramic capacitors physically close to the MOSFET VIN pins (switching MOSFET drain) and the Schottky diode anode.

The important parameters for the bulk input capacitance are the voltage rating and the RMS current rating. For reliable operation, select bulk capacitors with voltage and current ratings above the maximum input voltage and largest RMS current required by the circuit. Their voltage rating should be at least 1.25 times greater than the maximum input voltage, while a voltage rating of 1.5 times is a conservative guideline. For most cases, the RMS current rating requirement for the input capacitor of a buck regulator is approximately 1/2 the DC load current.

The maximum RMS current required by the regulator may be closely approximated through the Equation 6:

$$I_{RMS\_MAX} = \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left( I_{OUT\_MAX}^2 + \frac{1}{12} \times \left( \frac{V_{IN} - V_{OUT}}{L \times f_s} \times \frac{V_{OUT}}{V_{IN}} \right)^2 \right)} \quad (EQ. 6)$$

For a through hole design, several electrolytic capacitors may be needed. For surface mount designs, solid tantalum capacitors can be used, but caution must be exercised with regard to the capacitor surge current rating. These capacitors must be capable of handling the surge-current at power-up. Some capacitor series available from reputable manufacturers are surge current tested.

### Feedback Compensation

Figure 2 highlights the voltage-mode control loop for a synchronous-rectified buck converter. The output voltage ( $V_{OUT}$ ) is regulated to the Reference voltage level. The error amplifier output ( $V_{E/A}$ ) is compared with the oscillator (OSC) triangular wave to provide a pulse-width modulated (PWM) wave with an amplitude of  $V_{IN}$  at the PHASE node. The PWM wave is smoothed by the output filter ( $L_O$  and  $C_O$ ).

The modulator transfer function is the small-signal transfer function of  $V_{OUT}/V_{E/A}$ . This function is dominated by a DC Gain and the output filter ( $L_O$  and  $C_O$ ), with a double pole break frequency at  $f_{LC}$  and a zero at  $f_{ESR}$ . The DC Gain of the modulator is simply the input voltage ( $V_{IN}$ ) divided by the peak-to-peak oscillator voltage  $\Delta V_{OSC}$ .

### Modulator Break Frequency Equations

$$f_{LC} = \frac{1}{2\pi \times \sqrt{L_O \times C_O}} \quad f_{ESR} = \frac{1}{2\pi \times ESR \times C_O} \quad (EQ. 7)$$

The compensation network consists of the error amplifier (internal to the ISL8501) and the impedance networks  $Z_{IN}$  and  $Z_{FB}$ . The goal of the compensation network is to provide a closed loop transfer function with the highest 0dB crossing frequency ( $f_{0dB}$ ) and adequate phase margin. Phase margin is the difference between the closed loop phase at  $f_{0dB}$  and  $180^\circ$ . The following equations relate the compensation network's poles, zeros and gain to the components ( $R_1$ ,  $R_2$ ,  $R_4$ ,  $C_1$ ,  $C_2$ , and  $C_3$ ) in Figure 2. Use these guidelines for locating the poles and zeros of the compensation network:

1. Pick Gain ( $R_2/R_1$ ) for desired converter bandwidth.

2. Place 1st Zero Below Filter's Double Pole ( $\sim 75\% f_{LC}$ ).
3. Place 2nd Zero at Filter's Double Pole.
4. Place 1st Pole at the ESR Zero.
5. Place 2nd Pole at Half the Switching Frequency.
6. Check Gain against Error Amplifier's Open-Loop Gain.
7. Estimate Phase Margin - Repeat if Necessary.

### Compensation Break Frequency Equations

$$f_{Z1} = \frac{1}{2\pi \times R_4 \times C_2} \quad f_{P1} = \frac{1}{2\pi \times R_4 \times \left( \frac{C_3 \times C_2}{C_3 + C_2} \right)}$$

$$f_{Z2} = \frac{1}{2\pi \times (R_1 + R_3) \times C_1} \quad f_{P2} = \frac{1}{2\pi \times R_3 \times C_1} \quad (EQ. 8)$$

Figure 3 shows an asymptotic plot of the DC/DC converter's gain vs frequency. The actual Modulator Gain has a high gain peak due to the high Q factor of the output filter and is not shown in Figure 3. Using the guidelines from "Modulator Break Frequency Equations" on page 17 should give a Compensation Gain similar to the curve plotted. The open loop error amplifier gain bounds the compensation gain. Check the compensation gain at  $f_{P2}$  with the capabilities of the error amplifier. The Closed Loop Gain is constructed on the graph of Figure 33 by adding the Modulator Gain (in dB) to the Compensation Gain (in dB). This is equivalent to multiplying the modulator transfer function to the compensation transfer function and plotting the gain.

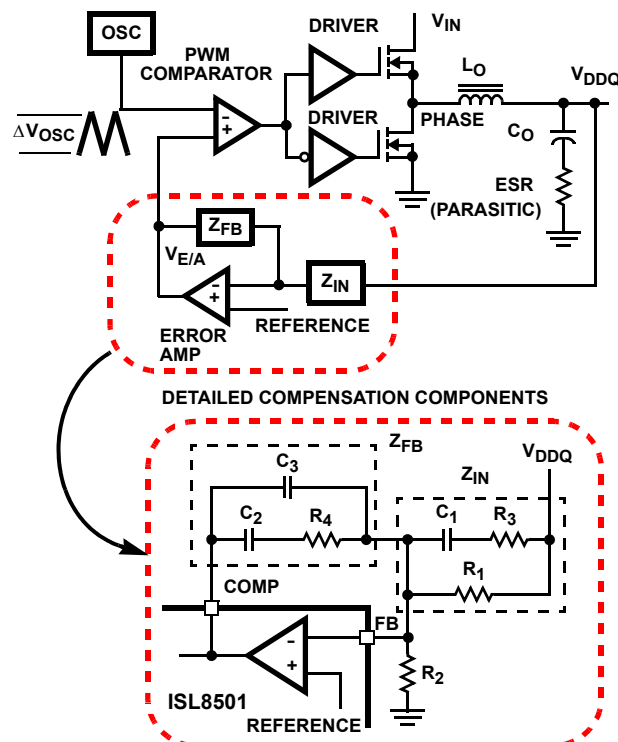

FIGURE 32. VOLTAGE-MODE BUCK CONVERTER COMPENSATION DESIGN AND OUTPUT VOLTAGE SELECTION

The compensation gain uses external impedance networks  $Z_{FB}$  and  $Z_{IN}$  to provide a stable, high bandwidth (BW) overall loop. A stable control loop has a gain crossing with -20dB/decade slope and a phase margin greater than 45°. Include worst case component variations when determining phase margin.

A more detailed explanation of voltage mode control of a buck regulator can be found in Tech Brief TB417, titled "Designing Stable Compensation Networks for Single Phase Voltage Mode Buck Regulators."

FIGURE 33. ASYMPTOTIC BODE PLOT OF CONVERTER GAIN

### Layout Considerations

Layout is very important in high frequency switching converter design. With power devices switching efficiently at 500kHz, the resulting current transitions from one device to another cause voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, radiate noise into the circuit, and lead to device overvoltage stress. Careful component layout and printed circuit board design minimizes these voltage spikes.

As an example, consider the turn-off transition of the upper MOSFET. Prior to turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is picked up by the Schottky diode. Any parasitic inductance in the switched current path generates a large voltage spike during the switching interval. Careful component selection, tight layout of the critical components, and short, wide traces minimizes the magnitude of voltage spikes.

There are two sets of critical components in the ISL8501 switching converter. The switching components are the most critical because they switch large amounts of energy, and therefore tend to generate large amounts of noise. Next are the small signal components, which connect to sensitive nodes or supply critical bypass current and signal coupling.

A multi-layer printed circuit board is recommended. Figure 34 shows the connections of the critical components in the converter. Note that capacitors  $C_{IN}$  and  $C_{OUT}$  could each represent numerous physical capacitors. Dedicate one solid layer (usually a middle layer of the PC board) for a ground plane and make

all critical component ground connections with vias to this layer. Dedicate another solid layer as a power plane and break this plane into smaller islands of common voltage levels. Keep the metal runs from the PHASE terminals to the output inductor short. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the phase nodes. Use the remaining printed circuit layers for small signal wiring.

In order to dissipate heat generated by the internal LDO and MOSFET, the ground pad, pin 29, should be connected to the internal ground plane through at least four vias. This allows the heat to move away from the IC and also ties the pad to the ground plane through a low impedance path.

The switching components should be placed close to the ISL8501 first. Minimize the length of the connections between the input capacitors,  $C_{IN}$ , and the power switches by placing them nearby. Position both the ceramic and bulk input capacitors as close to the upper MOSFET drain as possible. Position the output inductor and output capacitors between the upper and lower MOSFETs and the load.

The critical small signal components include any bypass capacitors, feedback components, and compensation components. Place the PWM converter compensation components close to the FB and COMP pins. The feedback resistors should be located as close as possible to the FB pin with vias tied straight to the ground plane as required.
