

Dual PLL Clock Generator

The MPC9100 is a dual PLL phase locked loop clock generator. The device synthesizes a 14.318 MHz input reference to provide a buffered copy of the input reference, a 31.3344MHz clock output and a 45.1584 clock output.

The device features a fully integrated crystal oscillator as the clock reference source. No external components are required other than the 14.318 MHz crystal. The TCLK input is used only for factory test and cannot be used as the PLL clock reference. To reduce total die area the PLL loop filter capacitors are brought outside the chip. The FCAP pins are used to connect these capacitors to the internal PLL's. 0.01µf capacitors are recommended.

The device features three synchronous output enable pins to allow for shutting down specific clocks. When driven to a logic LOW the OE pins will freeze the selected clock in its low state. Internal timing has been established that guarantee transition into and out of the freeze state will not produce output glitches. These control inputs have internal pull up resistors so that they will default to the output active state.

The TEST0–2 pins allow for the testing of the internal logic of the device. Most of the states are reserved for factory test use with one exception. When the TEST 0 pin is driven low the internal state machines will be reset and the outputs will be driven into high impedance. The TEST pins also have internal pull up resistors such that they will default into the normal operation mode of the chip.

The MPC9100 features separate internal power buses to try to isolate the output noise from the internal PLL's and the other outputs. The VCCA pins are the power supply pins for the analog PLL's, the VCCI pin is the power supply for the internal core logic and the VCCO's are the power pins for the output buffers. All of these pins should be tied to a common power plane on the printed circuit board.

## APPLICATIONS INFORMATION

## Power Supply Filtering

The MPC9100 is a mixed analog/digital product and as such it exhibits some sensitivities that would not necessarily be seen on a fully digital product. Analog circuitry is naturally susceptible to random noise, especially if this noise is seen on the power supply pins. The MPC9100 provides separate power supplies for the output buffers ( $V_{CCO}$ ) and the internal PLL ( $V_{CCA}$ ) of the device. The purpose of this design technique is to try and isolate the high switching noise digital outputs from the relatively sensitive internal analog phase-locked loop. In a controlled environment such as an evaluation board this level of isolation is sufficient. However, in a digital system environment where it is more difficult to minimize noise on the power supplies a second level of isolation may be required. The simplest form of isolation is a power supply filter on the  $V_{CCA}$  pin for the MPC9100.

### Figure 2. Power Supply Filter

Figure 2 illustrates a typical power supply filter scheme. The MPC9100 is most susceptible to noise with spectral content in the 1KHz to 1MHz range. Therefore the filter should be designed to target this range. The key parameter that needs to be met in the final filter design is the DC voltage drop that will be seen between the  $V_{CC}$  supply and the VCCA pin of the MPC9100. The current into the VCCA pin is typically 15mA (20mA maximum), assuming that a minimum of 3.0V must be maintained on the PLL\_VCC pin very little DC voltage drop can be tolerated when a 3.3V  $V_{CC}$  supply is used. The resistor shown in Figure 2 must have a resistance of 10–15 $\Omega$  to meet the voltage drop criteria. The RC filter pictured will provide a broadband filter with approximately 100:1 attenuation for noise whose spectral content is above 20KHz. As the noise frequency crosses the series resonant point of an individual capacitor it's overall impedance begins to look inductive and thus increases with increasing frequency. The parallel capacitor combination shown ensures that a low impedance path to ground exists for frequencies well above the bandwidth of the PLL.

A higher level of attenuation can be achieved by replacing the resistor with an appropriate valued inductor. A 1000 $\mu$ H choke will show a significant impedance at 10KHz frequencies and above. Because of the current draw and the voltage that must be maintained on the PLL\_VCC pin a low DC resistance inductor is required (less than 15 $\Omega$ ). Generally the resistor/capacitor filter will be cheaper, easier to implement and provide an adequate level of supply filtering.

Although the MPC9100 has several design features to minimize the susceptibility to power supply noise (isolated power and grounds and fully differential PLL) there still may be applications in which overall performance is being degraded due to system power supply noise. The power supply filter schemes discussed in this section should be adequate to eliminate power supply noise related problems in most designs.

### Using the On-Board Crystal Oscillator

The MPC9100 features an on-board crystal oscillator to allow for seed clock generation as well as final distribution. The on-board oscillator is completely self contained so that the only external component required is the crystal. As the oscillator is somewhat sensitive to loading on its inputs the user is advised to mount the crystal as close to the MPC9100 as possible to avoid any board level parasitics. To facilitate co-location surface mount crystals are recommended, but not required. In addition, with crystals with a higher shunt capacitance, it may be necessary to place a 1k resistor across the two crystal leads.

The oscillator circuit is a series resonant circuit as opposed to the more common parallel resonant circuit, this eliminates the need for large on-board capacitors. Because the design is a series resonant design for the optimum frequency accuracy a series resonant crystal should be used (see specification table below). Unfortunately most off the shelf crystals are characterized in a parallel resonant mode. However a parallel resonant crystal is physically no different

than a series resonant crystal, a parallel resonant crystal is simply a crystal which has been characterized in its parallel resonant mode. Therefore in the majority of cases a parallel specified crystal can be used with the MPC9100 with just a minor frequency error due to the actual series resonant frequency of the parallel resonant specified crystal. Typically a parallel specified crystal used in a series resonant mode will exhibit an oscillatory frequency a few hundred ppm lower than the specified value. For most processor implementations a few hundred ppm translates into kHz inaccuracies, a level which does not represent a major issue.

**Table 1. Crystal Specifications**

Parameter	Value
Crystal Cut	Fundamental AT Cut
Resonance	Series Resonance*
Frequency Tolerance	$\pm 75$ ppm at 25°C
Frequency/Temperature Stability	$\pm 150$ ppm 0 to 70°C
Operating Range	0 to 70°C
Shunt Capacitance	5–7pF
Equivalent Series Resistance (ESR)	50 to 80 $\Omega$
Correlation Drive Level	100 $\mu$ W
Aging	5ppm/Yr (First 3 Years)

\* See accompanying text for series versus parallel resonant discussion.

### Driving Transmission Lines

The MPC9100 clock driver was designed to drive high speed signals in a terminated transmission line environment. To provide the optimum flexibility to the user the output drivers were designed to exhibit the lowest impedance possible. With an output impedance of less than 10 $\Omega$  the drivers can drive either parallel or series terminated transmission lines. For more information on transmission lines the reader is referred to application note AN1091 in the Timing Solutions brochure (BR1333/D).

In most high performance clock networks point-to-point distribution of signals is the method of choice. In a point-to-point scheme either series terminated or parallel terminated transmission lines can be used. The parallel technique terminates the signal at the end of the line with a 50 $\Omega$  resistance to  $V_{CC}/2$ . This technique draws a fairly high level of DC current and thus only a single terminated line can be driven by each output of the MPC9100 clock driver. For the series terminated case however there is no DC current draw, thus the outputs can drive multiple series terminated lines. Figure 3 illustrates an output driving a single series terminated line vs two series terminated lines in parallel. When taken to its extreme the fanout of the MPC9100 clock driver is effectively doubled due to its capability to drive multiple lines.

Figure 3. Single versus Dual Transmission Lines

The waveform plots of Figure 4 show the simulation results of an output driving a single line vs two lines. In both cases the drive capability of the MPC9100 output buffers is more than sufficient to drive 50Ω transmission lines on the incident edge. Note from the delay measurements in the simulations a delta of only 43ps exists between the two differently loaded outputs. This suggests that the dual line driving need not be used exclusively to maintain the tight output-to-output skew of the MPC9100. The output waveform in Figure 4 shows a step in the waveform, this step is caused by the impedance mismatch seen looking into the driver. The parallel combination of the 43Ω series resistor plus the output impedance does not match the parallel combination of the line impedances. The voltage wave launched down the two lines will equal:

$$V_L = V_S \left( Z_0 / (R_S + R_o + Z_0) \right)$$

$$Z_0 = 50\Omega \parallel 50\Omega$$

$$R_S = 43\Omega \parallel 43\Omega$$

$$R_o = 7\Omega$$

$$V_L = 3.0 \left( 25 / (21.5 + 7 + 25) \right) = 3.0 \left( 25 / 53.5 \right) = 1.40V$$

At the load end the voltage will double, due to the near unity reflection coefficient, to 2.8V. It will then increment towards the quiescent 3.0V in steps separated by one round trip delay (in this case 4.0ns).

Figure 4. Single versus Dual Waveforms

Since this step is well above the threshold region it will not cause any false clock triggering, however designers may be uncomfortable with unwanted reflections on the line. To better match the impedances when driving multiple lines the situation in Figure 5 should be used. In this case the series terminating resistors are reduced such that when the parallel combination is added to the output buffer impedance the line impedance is perfectly matched.

Figure 5. Optimized Dual Line Termination

SPICE level output buffer models are available for engineers who want to simulate their specific interconnect schemes. In addition IV characteristics are in the process of being generated to support the other board level simulators in general use.

## NOTES:

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: MILLIMETER.
3. DATUM PLANE -AB- IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
4. DATUMS -T-, -U-, AND -Z- TO BE DETERMINED AT DATUM PLANE -AB-.
5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE -AC-.
6. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.250 (0.010) PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE -AB-.
7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. DAMBAR PROTRUSION SHALL NOT CAUSE THE D DIMENSION TO EXCEED 0.520 (0.020).
8. MINIMUM SOLDER PLATE THICKNESS SHALL BE 0.0076 (0.0003).
9. EXACT SHAPE OF EACH CORNER MAY VARY FROM DEPICTION.
