

DRAM

1 MEG x 4 DRAM

FAST PAGE MODE, WRITE-PER-BIT

DRAM

FEATURES

- Industry standard x4 pinout, timing, functions and packages
- High performance, CMOS silicon gate process
- Single +5V±10% power supply
- Low power, 3mW standby; 225mW active, typical
- All inputs, outputs and clocks are fully TTL and CMOS compatible
- 1024-cycle refresh distributed across 16ms
- Refresh modes: $\overline{\text{RAS}}$ -ONLY, $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$ (CBR), and HIDDEN
- WRITE-PER-BIT access cycle (nonpersistent)
- 300 and 350 mil wide SOJ packages
- Two CBR options: CBR with $\overline{\text{WE}}$ a don't care (1 Meg compatible) and CBR with $\overline{\text{WE}}$ a HIGH (JEDEC test mode capable via WCBR)

OPTIONS

- Timing
 - 60ns access
 - 70ns access
 - 80ns access
- Packages
 - Ceramic DIP (400mil)
 - Plastic ZIP (350mil)
 - Plastic SOJ (300mil)
 - Plastic SOJ (350mil)
 - Plastic TSOP (*)
- $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$ refresh
 - CBR with $\overline{\text{WE}}$ a don't care
 - CBR with $\overline{\text{WE}}$ a HIGH
- Operating Temperature, T_A
 - Commercial (0°C to +70°C)
 - Industrial (-40°C to +85°C)

GENERAL DESCRIPTION

The MT4C4005 is a randomly accessed solid-state memory containing 4,194,304 bits organized in a x4 configuration. During READ or WRITE cycles each bit is uniquely addressed through the 20 address bits, which are entered 10 bits (A0-A9) at a time. $\overline{\text{RAS}}$ is used to latch the first 10 bits and $\overline{\text{CAS}}$ the latter 10 bits. A READ or WRITE cycle is selected with the $\overline{\text{WE}}$ input. A logic HIGH on $\overline{\text{WE}}$ dictates READ mode while a logic LOW on $\overline{\text{WE}}$ dictates WRITE mode. During a WRITE cycle, data in (D) is latched by the falling

edge of $\overline{\text{WE}}$ or $\overline{\text{CAS}}$, whichever occurs last. If $\overline{\text{WE}}$ goes LOW prior to $\overline{\text{CAS}}$ going LOW, the output pin(s) remain open (High-Z) until the next $\overline{\text{CAS}}$ cycle. If $\overline{\text{WE}}$ goes LOW after data reaches the output pin(s), data out (Q) is activated and retains the selected cell data as long as $\overline{\text{CAS}}$ remains low (regardless of $\overline{\text{WE}}$ or $\overline{\text{RAS}}$). This late $\overline{\text{WE}}$ pulse results in a READ-WRITE cycle. The four data inputs and four data outputs are routed through four pins using common I/O, and pin direction is controlled by $\overline{\text{WE}}$ and $\overline{\text{OE}}$. The WRITE-PER-BIT feature allows the user to define WRITE MASK during a WRITE cycle when $\overline{\text{RAS}}$ goes LOW, depending on the state of $\overline{\text{WE}}$.

FAST PAGE MODE operations allow faster data operations (READ, WRITE or READ-MODIFY-WRITE) within a row address (A0-A9) defined page boundary. The FAST PAGE MODE cycle is always initiated with a row address strobed-in by $\overline{\text{RAS}}$ followed by a column address strobed-in by $\overline{\text{CAS}}$. $\overline{\text{CAS}}$ may be toggled-in by holding $\overline{\text{RAS}}$ LOW and strobing-in different column addresses, thus executing faster memory cycles. Returning $\overline{\text{RAS}}$ HIGH terminates the FAST PAGE MODE operation.

Returning $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ HIGH terminates a memory cycle and decreases chip current to a reduced standby level. Also, the chip is preconditioned for the next cycle during the $\overline{\text{RAS}}$ high time. Memory cell data is retained in its correct state by maintaining power and executing any $\overline{\text{RAS}}$ cycle (READ, WRITE, $\overline{\text{RAS}}$ -ONLY, $\overline{\text{CAS}}$ -BEFORE- $\overline{\text{RAS}}$, or HIDDEN refresh) so that all 1024 combinations of $\overline{\text{RAS}}$ addresses (A0-A9) are executed at least every 16ms, regardless of sequence. The CBR refresh cycle will invoke the internal refresh counter for automatic $\overline{\text{RAS}}$ addressing.

FUNCTIONAL BLOCK DIAGRAM FAST PAGE MODE

*NOTE: $\overline{WE}$ LOW prior to $\overline{CAS}$ LOW, EW detection CKT output is a HIGH (EARLY WRITE)
 $\overline{CAS}$ LOW prior to $\overline{WE}$ LOW, EW detection CKT output is a LOW (LATE WRITE)

ABSOLUTE MAXIMUM RATINGS*

Voltage on Vcc supply relative to Vss	-1.0V to +7.0V
Storage Temperature (Ceramic)	-65°C to +150°C
Storage Temperature (Plastic)	-55°C to +150°C
Power Dissipation	1W
Short Circuit Output Current	50mA

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

MASKED WRITE ACCESS CYCLE

Every WRITE access cycle can be a MASKED WRITE, depending on the state of $\overline{WE}$ at $\overline{RAS}$ time. A MASKED WRITE is selected when $\overline{WE}$ is LOW at $\overline{RAS}$ time and mask data is supplied on the DQ pins.

The mask data present on the DQ1-DQ4 inputs at $\overline{RAS}$ time will be written to an internal mask data register and will then act as an individual write enable for each of the corresponding DQ inputs. If a LOW (logic "0") is written to a mask data register bit, the input port for that bit is disabled during the subsequent WRITE operation and no new data will be written to that DRAM cell location. A HIGH (logic

"1") on a mask data register bit enables the input port and allows normal WRITE operations to proceed. At $\overline{CAS}$ time, the bits present on the DQ1-DQ4 inputs will be either written to the DRAM (if the mask data bit was HIGH) or ignored (if the mask data bit was LOW).

For nonpersistent MASK WRITES, new mask data must be supplied each time a MASKED WRITE cycle is initiated.

Figure 1 illustrates the MT4C4005 MASKED WRITE operation (Note: $\overline{RAS}$ or $\overline{CAS}$ time refers to the time at which $\overline{RAS}$ or $\overline{CAS}$ transition from HIGH to LOW).

NOTES

1. All voltages referenced to Vss.
2. This parameter is sampled. Capacitance is calculated from the equation $C = I^{dt}/dv$ with $dv = 3V$ and $V_{CC} = 5V$.
3. Icc is dependent on cycle rates.
4. Icc is dependent on output loading and cycle rates. Specified values are obtained with minimum cycle time and the outputs open.
5. Enables on-chip refresh and address counters.
6. The minimum specifications are used only to indicate cycle time at which proper operation over the full temperature range is assured.
7. An initial pause of 100 μ s is required after power-up followed by eight $\overline{RAS}$ refresh cycles ($\overline{RAS}$ -ONLY or CBR with $\overline{WE}$ HIGH) before proper device operation is assured. The eight $\overline{RAS}$ cycle wake-up should be repeated any time the 16ms refresh requirement is exceeded.
8. AC characteristics assume $t_T = 5ns$.
9. V_{IH} (MIN) and V_{IL} (MAX) are reference levels for measuring timing of input signals. Transition times are measured between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}).
10. In addition to meeting the transition rate specification, all input signals must transit between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}) in a monotonic manner.
11. If $\overline{CAS} = V_{IH}$, data output is high impedance.
12. If $\overline{CAS} = V_{IL}$, data output may contain data from the last valid READ cycle.
13. Measured with a load equivalent to 2 TTL gates and 100pF.
14. Assumes that $t_{RCD} < t_{RCD} (MAX)$. If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the value shown.
15. Assumes that $t_{RCD} \geq t_{RCD} (MAX)$.
16. If $\overline{CAS}$ is LOW at the falling edge of $\overline{RAS}$, Q will be maintained from the previous cycle. To initiate a new cycle and clear the data out buffer, $\overline{CAS}$ must be pulsed HIGH for t_{CPN} .
17. Operation within the $t_{RCD} (MAX)$ limit ensures that $t_{RAC} (MAX)$ can be met. $t_{RCD} (MAX)$ is specified as a reference point only; if t_{RCD} is greater than the specified $t_{RCD} (MAX)$ limit, then access time is controlled exclusively by t_{CAC} .
18. Operation within the $t_{RAD} (MAX)$ limit ensures that $t_{RCD} (MAX)$ can be met. $t_{RAD} (MAX)$ is specified as a reference point only; if t_{RAD} is greater than the specified $t_{RAD} (MAX)$ limit, then access time is controlled exclusively by t_{AA} .
19. Either t_{RCH} or t_{RRH} must be satisfied for a READ cycle.
20. $t_{OFF} (MAX)$ defines the time at which the output achieves the open circuit condition and is not referenced to V_{OH} or V_{OL} .
21. t_{WCS} , t_{RWD} , t_{AWD} and t_{CWD} are restrictive operating parameters in late WRITE, and READ-MODIFY-WRITE cycles only. If $t_{WCS} \geq t_{WCS} (MIN)$, the cycle is an EARLY-WRITE cycle and the data output will remain an open circuit through out the entire cycle. If $t_{RWD} \geq t_{RWD} (MIN)$, $t_{AWD} \geq t_{AWD} (MIN)$ and $t_{CWD} \geq t_{CWD} (MIN)$, the cycle is a READ-MODIFY-WRITE and the data output will contain data read from the selected cell. If neither of the above conditions are met, the state of data out are indeterminate. $\overline{OE}$ held HIGH and $\overline{WE}$ taken LOW after $\overline{CAS}$ goes LOW results in a LATE-WRITE ($\overline{OE}$ controlled) cycle.
22. These parameters are referenced to $\overline{CAS}$ leading edge in EARLY-WRITE cycles and $\overline{WE}$ leading edge in LATE-WRITE or READ-MODIFY-WRITE cycles.
23. If $\overline{OE}$ is tied permanently LOW, LATE-WRITE or READ-MODIFY-WRITE operations are not possible.
24. A HIDDEN REFRESH may also be performed after a WRITE cycle. In this case, $\overline{WE} = LOW$ and $\overline{OE} = HIGH$.
25. t_{WTS} and t_{WTH} are setup and hold specifications for the $\overline{WE}$ pin being held LOW to enable the JEDEC test mode (with CBR timing constraints). These two parameters are the inverses of t_{WRP} and t_{WRH} in the CBR refresh cycle.
26. LATE-WRITE and READ-MODIFY-WRITE cycles must have both t_{OD} and t_{OE} met ($\overline{OE}$ HIGH during WRITE cycle) in order to ensure that the output buffers will be open during the WRITE cycle. The DQs will provide the previously read data if $\overline{CAS}$ remains LOW and $\overline{OE}$ is taken back LOW after t_{OE} is met. If $\overline{CAS}$ goes HIGH prior to $\overline{OE}$ going back LOW, the DQs will remain open.
27. The DQs open during READ cycles once t_{OD} or t_{OFF} occur. If $\overline{CAS}$ goes HIGH first, $\overline{OE}$ becomes a don't care. If $\overline{OE}$ goes HIGH and $\overline{CAS}$ stays LOW, $\overline{OE}$ is not a don't care; and the DQs will provide the previously read data if $\overline{OE}$ is taken back LOW (while $\overline{CAS}$ remains LOW).

4 MEG POWER-UP AND REFRESH CONSTRAINTS

The JEDEC 4 Meg DRAM introduces two potential incompatibilities compared to the previous generation 1 Meg DRAM. The incompatibilities involve refresh and power-up. Understanding these incompatibilities and providing for them will offer the designer and system user greater compatibility between the 1 Meg and 4 Meg.

REFRESH

The most commonly used refresh mode of the 1 Meg is the CBR (CAS-BEFORE-RAS) REFRESH cycle. The CBR for the 1 Meg specifies the $\overline{WE}$ pin as a don't care. The 4 Meg, on the other hand, specifies the CBR REFRESH mode to be a $\overline{WCBR}$, which is CBR with the $\overline{WE}$ pin held at a logical HIGH level.

The reason for $\overline{WCBR}$ instead of CBR on the 4 Meg is that a CBR cycle with $\overline{WE}$ LOW will put the 4 Meg into the JEDEC specified test mode ($\overline{WCBR}$). In contrast, the 1 Meg test mode is entered by applying a HIGH signal to the test pin (pin 4 on DIP, pin 5 on SOJ and pin 8 on ZIP). This HIGH signal is usually a "supervoltage" (V in $\geq 7.5V$) so normal TTL or CMOS HIGH levels will not cause the part to enter the test mode.

POWER-UP

The 4 Meg $\overline{WCBR}$ constraint may also introduce another problem. The 1 Meg POWER-UP cycle requires a 100 μ s delay followed by any 8 RAS cycles. The 4 Meg POWER-UP is more restrictive in that 8 RAS-ONLY or CBR REFRESH ($\overline{WE}$ held HIGH) cycles must be used. The restriction is needed since the 4 Meg may power-up in the JEDEC specified test mode

and must exit out of the test mode. The only way to exit the 4 Meg JEDEC test mode is with either a $\overline{RAS}$ -ONLY or a $\overline{WCBR}$ REFRESH cycle.

SUMMARY

1. The optional 1 Meg test pin is the A10 pin on the 4 Meg (x1 only).
2. For optional test mode, the 1 Meg requires a valid HIGH on the test pin while the 4 Meg requires a CBR cycle with $\overline{WE}$ LOW.
3. The 1 Meg CBR REFRESH allows the $\overline{WE}$ pin to be don't care while the 4 Meg CBR requires $\overline{WE}$ to be HIGH ($\overline{WCBR}$).
4. The 8 $\overline{RAS}$ wake-up cycles on the 1 Meg may be any valid RAS cycle while the 4 Meg may only use RAS-ONLY or $\overline{WCBR}$ REFRESH cycles.

SPECIAL FEATURE

A memory system currently using 1 Meg DRAMs with $\overline{WE}$ as a don't care during CBR REFRESH does not allow for direct upgrading to 4 Meg DRAMs. Micron, realizing some companies will have this situation, provides a special feature on its 4 Meg DRAM, that requires "supervoltage" to access the 4 Meg JEDEC $\overline{WCBR}$ test function. This allows the Micron 4 Meg DRAM to be refreshed in the same manner as any 1 MEG DRAM. Note that the eight power-up cycles should only be refresh cycles in order to guarantee that any 4 Meg DRAM, including Micron's, does not inadvertently power-up in the test mode.

COMPARISON OF 4 MEG TEST MODE AND $\overline{WCBR}$ TO 1 MEG CBR
