# RC4277

## Dual Precision Operational Amplifiers

### Features

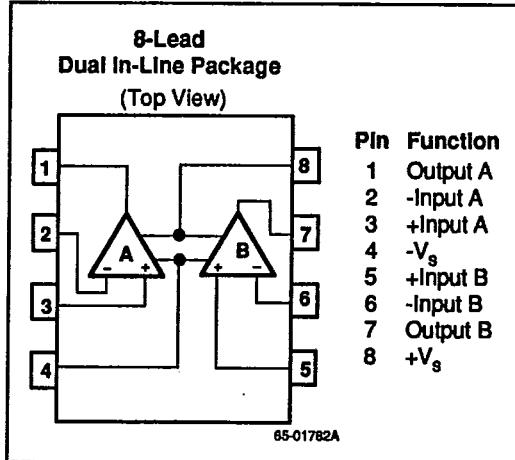

- High dc precision
- Very low  $V_{os}$  — 30  $\mu V$  max
- Very low  $V_{os}$  drift — 0.3  $\mu V/C$  max
- High open-loop gain — 5M min
- High CMRR — 120 dB min
- High PSRR — 110 db min
- Low noise — 0.35  $\mu V_{pp}$  (0.1 to 10 Hz)
- Low bias current — 4.0 nA max
- Low power consumption — 120 mW max

drift, and noise levels also support high precision operation.

The high performance of the RC4277 results from two innovative and unconventional manufacturing steps, plus careful circuit layout and design. The key steps are SiCr thin-film resistor deposition and post-package trimming of the input offset voltage characteristic. The low  $\pm 30 \mu V$  max  $V_{os}$  specification is maintained in high-volume production by way of the post-package trim procedure, where internal resistors are trimmed through the device input leads at the final test operation. Devices retain this low offset through the stability and accuracy of the trimmed thin-film resistors.

The RC4277 is available in 8-lead plastic and ceramic DIPs, and can be ordered with Mil-Std-883 Level B processing.

### Connection Information

### Description

The RC4277 provides the highest precision available in a dual bipolar operational amplifier. A monolithic dual version of the RC4077, the RC4277 is designed to replace OP-207, LT1002, OP-07 and OP-77 type amplifiers in applications requiring high PC board layout density. The RC4277 has a well-balanced, mutually supporting set of input specifications. Low  $V_{os}$ , low  $I_B$ , high open-loop gain, and excellent matching characteristics combine to raise the performance level of many instrumentation, low-level signal conditioning, and data conversion applications. ## Notes:

1. Long Term Input Offset Voltage Stability refers to the averaged trend line of  $V_{os}$  vs. Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in  $V_{os}$  during the first 30 operating days are typically  $2.5 \mu V$ .
2. Guaranteed by design.
3. Input Offset Voltage measurements are performed by automated test equipment approximately 0.5 seconds after application of power.
4. The input protection diodes do not allow the device to be removed or inserted into the circuit without first removing power.
