CMOS SERIAL E²PROM

S-29LX94A Series

The S-29LX94A Series is low power 1K/2K/4K-bit serial E²PROMs with a low operating voltage range. They are organized as 64-word × 16-bit, 128-word × 16-bit and 256-word × 16-bit, respectively. Each is capable of sequential read, where addresses are automatically incremented in 16-bit blocks.

The S-29LX94A Series is capable of protecting the memory, 50% of which can be protected starting from address 00.

Interface is structured so that this IC can be directly connected to the CPU with serial ports. 8-bit instructions make it easy to prepare your own software.

■ Features

- Low power consumption
 - Standby : 0.8 μ A Max. ($V_{CC} = 5.5$ V)
 - Operating : 0.8 mA Max. ($V_{CC} = 5.5$ V)
 - 0.4 mA Max. ($V_{CC} = 2.7$ V)
- Low operating voltage range
 - Write : 1.8 to 5.5 V
 - Read : 1.8 to 5.5 V
- Sequential read capable
- Memory Protection
- Can be easily connected to the serial port
- CS Active "L"
- Endurance : 10⁵ cycles/word
- Data retention : 10 years
- S-29L194A : 1 Kbits
- S-29L294A : 2 Kbits
- S-29L394A : 4 Kbits

Input data is retrieved on the rising edge of \overline{SK} .
Output data is triggered on the falling edge of \overline{SK} .

Figure3 Timing Chart

Figure4 Timing Chart for t_{CSS} and t_{CSH} when \overline{SK} is "H"

■ Operation

Instructions (in the order of start-bit, instruction, address, and data) are latched to DI in synchronization with the rising edge of \overline{SK} after \overline{CS} goes low. A start-bit can only be recognized when the high of DI is latched at the rising edge of \overline{SK} after changing \overline{CS} to low, it is impossible for it to be recognized as long as DI is low, even if there are \overline{SK} pulses after \overline{CS} goes low. Instruction finishes when \overline{CS} goes high, where it must be high between commands during t_{CDS} .

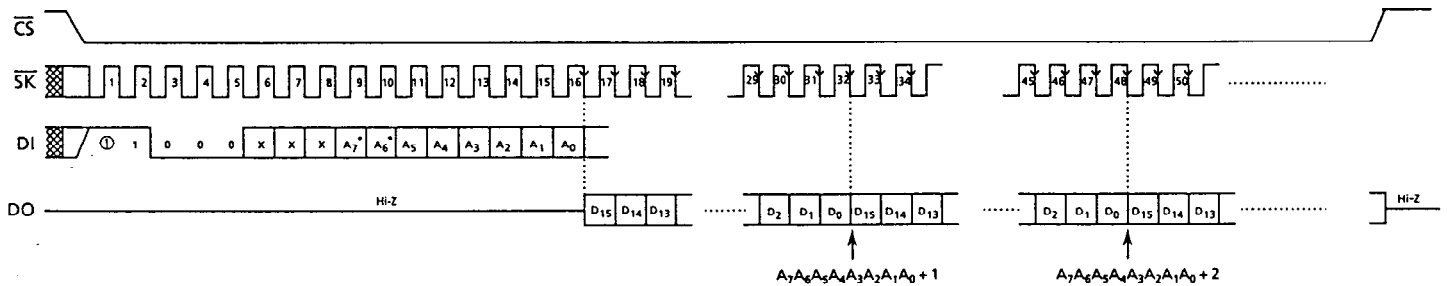

All input, including DI and \overline{SK} signals, is ignored while \overline{CS} is high, which is stand-by mode. The start bit + instruction, address, and data are 8-bit instructions. This makes it easy to prepare your own software using a serial interface incorporated into the CPU.

1. READ

The READ instruction reads data from a specified address. After A0 is latched at the rising edge of \overline{SK} , 16-bit data is continuously output in synchronization with the falling edge of \overline{SK} .

When all of the data (D₁₅ to D₀) in the specified address has been read, data in the next address can be read with the input of another \overline{SK} clock. Thus, the data over whole area of the memory can be read by continuously inputting \overline{SK} clocks as long as \overline{CS} is low.

The last address (A_n ... A₁ A₀ = 1 ... 11) rolls over to the top address (A_n ... A₁ A₀ = 0 ... 00).

* On the S-29L194A, A₇ and A₆ are optional.
On the S-29L294A, A₇ is optional.

Figure 5 Read Timing (S-29L394A)

2. PROGRAM

The PROGRAM instruction automatically begins writing to the non-volatile memory when \overline{CS} goes high at the completion of the specified clock input.

The write operation is completed in 10 ms (t_{PR} Max.), and the typical write period is less than 5 ms. In the S-29LX94A Series, it is easy to VERIFY the completion of the write operation in order to minimize the write cycle by setting \overline{CS} to low and checking the DO pin, which is low during the write operation and high after its completion. This VERIFY procedure can be executed over and over again.

There are two methods to detect a change in the DO output. One is to detect a change from low to high setting \overline{CS} to low, and the other is to detect a change from low to high as a result of repetitious operations of returning the \overline{CS} to high after setting \overline{CS} to low and checking the DO output.

Because all \overline{SK} and DI inputs are ignored during the write operation, any input of instruction will also be disregarded. When DO outputs high after completion of the write operation or if it is in the high-impedance state (Hi-Z), the input of instructions is available. Even if the DO pin remains high, it will enter the high-impedance state upon the recognition of a high of DI (start-bit) attached to the rising edge of an \overline{SK} pulse.

DI input should be low during the VERIFY procedure.

2.1 PROGRAM

This instruction writes 16-bit data to a specified address.

After changing \overline{CS} to low, input a start-bit, op-code (PROGRAM), address, and 16-bit data. If there is a data overflow of more than 16 bits, only the last 16-bits of the data is considered valid. Changing \overline{CS} to high will start the PROGRAM operation. It is not necessary to make the data "1" before initiating the PROGRAM operation.

* On the S-29L194A, A₇ and A₆ are optional.
On the S-29L294A, A₇ is optional.

Figure 6 WRITE Timing (S-29L394A)

3. Write enable (PEN) and Write disable (PDS)

The PEN instruction puts the S-29LX94A Series into write enable mode, which accepts PROGRAM instruction. The PDS instruction puts the S-29LX94A Series into write disable mode, which refuses PROGRAM instruction.

The S-29LX94A Series powers on in write disable mode, which protects data against unexpected, erroneous write operations caused by noise and/or CPU malfunctions. It should be kept in write disable mode except when performing write operations.

Figure 7 PEN/PDS Timing

■ Receiving a Start-Bit

A start-bit can be recognized by latching the high level of DI at the rising edge of SK-bar after changing CS-bar to low (Start-Bit Recognition). The write operation begins by inputting the write instruction and setting CS-bar to high. The DO pin then outputs low during the write operation and high at its completion by setting CS-bar to low (Verify Operation). Therefore, only after a write operation, in order to accept the next command by having CS-bar go low, the DO pin is switched from a state of high-impedence to a state of data output; but if it recognizes a start-bit, the DO pin returns to a state of high-impedence (see Figure 3).

Make sure that data output from the CPU does not interfere with the data output from the serial memory IC when you configure a 3-wire interface by connecting DI input pin and DO output pin. Such interference may cause a start-bit fetch problem.

■ Three-wire Interface (DI-DO direct connection)

Although the normal configuration of a serial interface is a 4-wire interface to CS-bar, SK-bar, DI, and DO, a 3-wire interface is also a possibility by connecting DI and DO. However, since there is a possibility that the DO output from the serial memory IC will interfere with the data output from the CPU with a 3-wire interface, install a resistor between DI and DO in order to give preference to data output from the CPU to DI (See Figure 8).

Figure 8 3-wire interface

■ Connecting to the CPU with a Serial Port

Figure 9 Connectin Example

Figure 10 Serial Shift Timing

■ Memory Protection

The S-29LX94A Series is capable of protecting the memory. So, the contents of the memory will not be miswritten due to error run or malfunction of the CPU. When the $\overline{\text{PROTECT}}$ terminal is connected to GND or OPEN, write to Bank 1 in the memory array is prohibited (50% of the memory can be protected starting from address 00). Because the pull-down resistance is connected to the $\overline{\text{PROTECT}}$ terminal internally, the memory can be automatically protected when the $\overline{\text{PROTECT}}$ terminal is OPEN. When the protection is valid, the data in the memory of Bank 1 will not be rewritten. However, because the write control circuit inside the IC functions, the next instruction cannot be executed during the time period of writing (t_{PR}). While write instruction is being input and write is being executed, always connect the $\overline{\text{PROTECT}}$ terminal to "H," "L" or OPEN, and leave the input signal unchanged (see Figure 11).
