

Descriptions

The S3843 is fixed Current PWM controller for Off-line and DC-DC converter applications. The internal circuits feature a trimmed oscillator for precise duty cycle control, a temperature compensated reference, high gain error amplifier current sensing comparator, and a high current totempole output for driving a power MOSFET. Protection circuitry includes built in under voltage lockout and current limiting. S3843 have UVLO threshold of 8.4V(on) and 7.6V(off). S3843 can operate within 100% duty cycle.

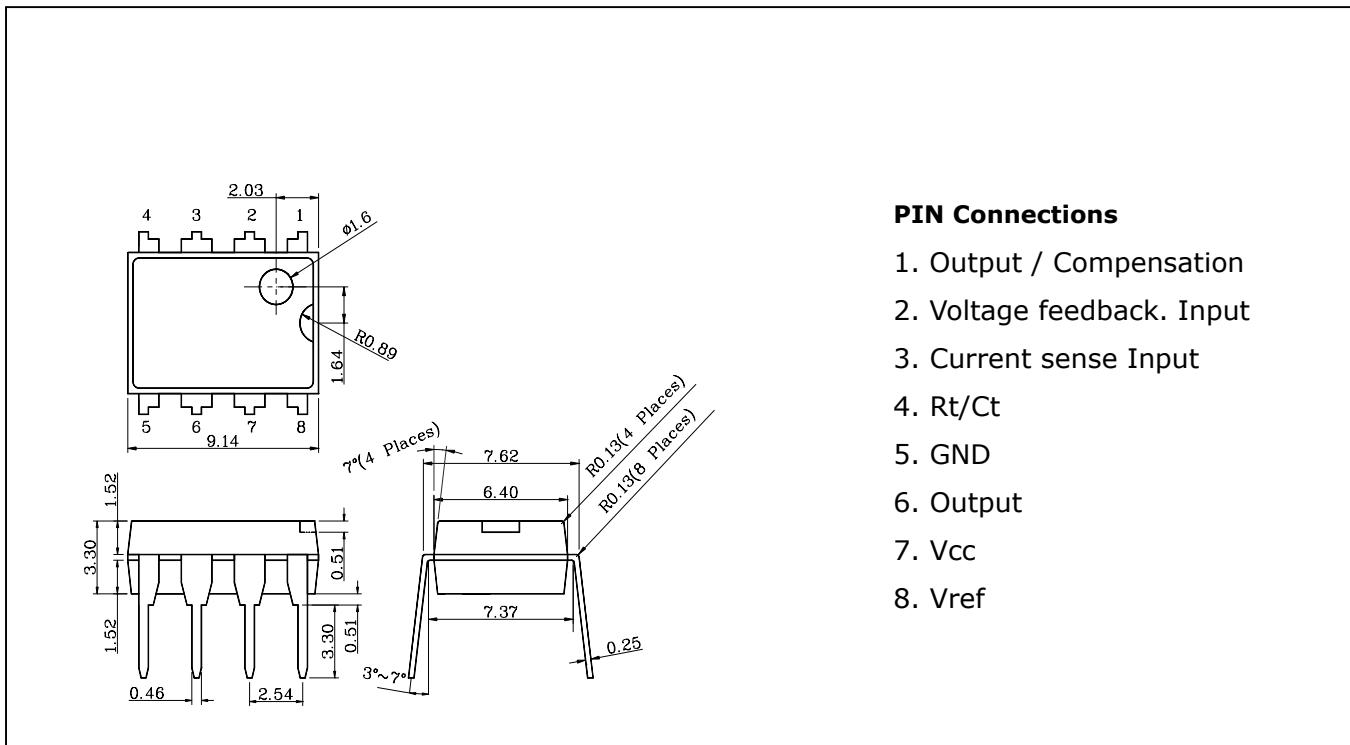

Features

- Optimized for off-line and DC to DC converters
- Low start up current < 1 mA
- Operating range up to 500 KHz
- Pulse-by-pulse current limiting
- Under Voltage Lock Out with hysteresis
- High current totempole output
- Short shutdown delay time ; typical 100nsec

Information in using IC

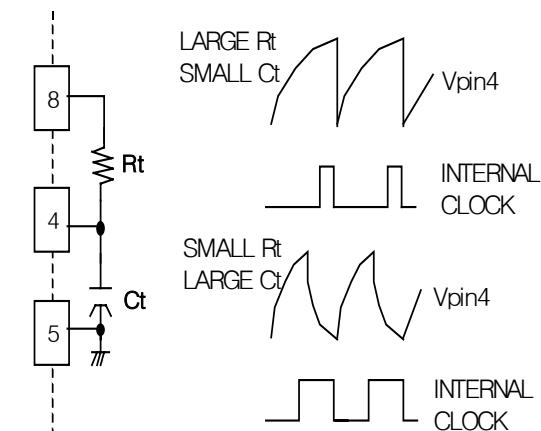

1. Under voltage Lockout

To prevent erratic output behavior which activating the power switch with extraneous leakage currents, during under voltage lockout. Output(pin6) should be shunted to ground with a bleeder resister.

The V_{cc} comparator upper and lower threshold are 8.4V/7.6V. The large hysteresis and low start up currents makes it ideally suited in off-line converter application where efficient bootstrap start-up techniques are required.

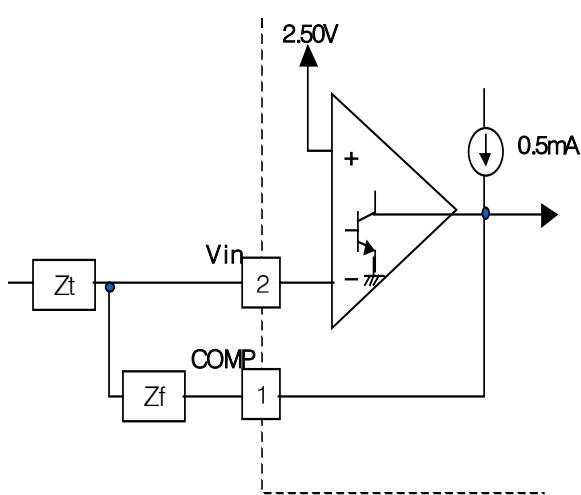

2. Oscillator Waveforms and Maximum Duty Cycle

The oscillator frequency is programmed by the values selected for the timing components R_t and C_t . C_t is charged from 5V, V_{ref} , through resistor R_t to approximately 2.8V and discharged to 1.2V by an internal current sink.

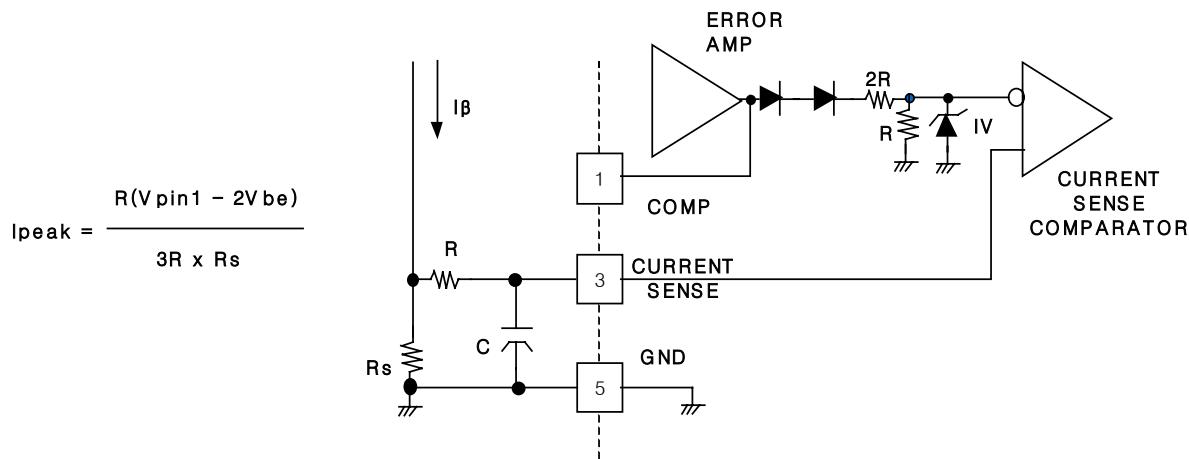

During the discharge of C_t , the oscillator generates an internal blanking pulse and the center input NOR gate high. This makes output to be in a low state and control the amount of output dead time.

3. Error AMP Configuration

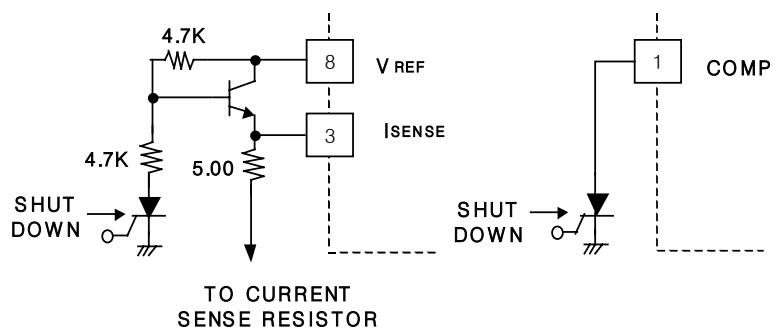

Error amp output(Pin1) is provided for external loop compensation and error amp can source or sink up to 0.5mA. The non-inverting input is internally biased at 2.5V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input(pin2).

4. Current Sense Circuit

A normal operating conditions occurs when the power supply output is overloaded or if output voltage to 1.0V. Therefore the maximum peak switch current is $I_{pk(max)}=1.0V/R_s$, and under the normal operating conditions the peak inductor current controlled by the voltage at pin1.

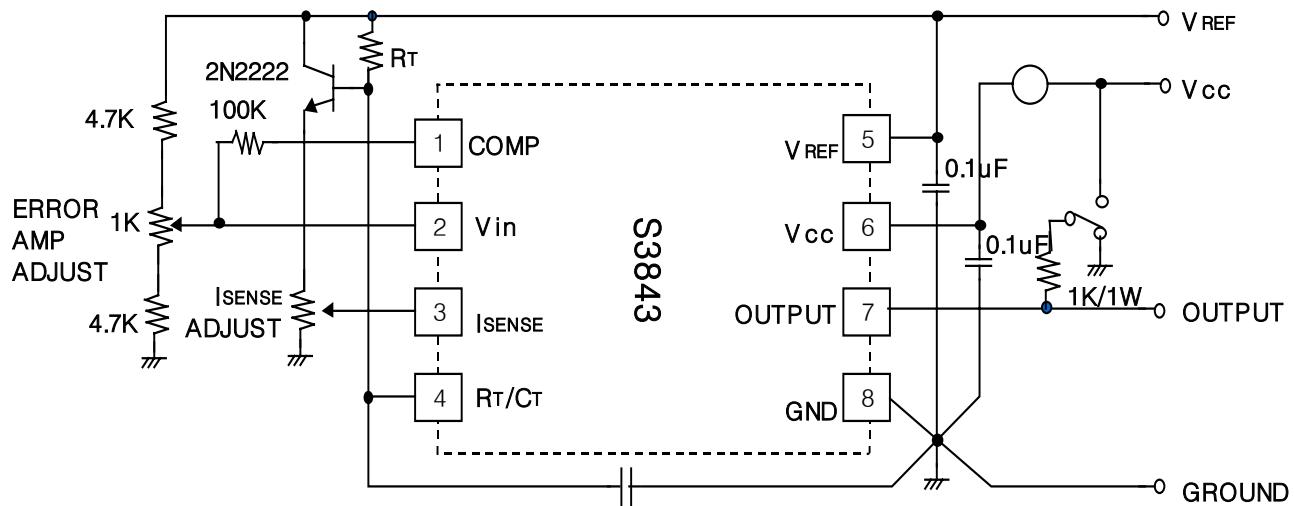

5. Shutdown Techniques

Shutdown of the S3843 can be accomplished by two methods; either raise pin3 above 1V or pull pin1 below a voltage two diodes drops above ground. Either causes the output of the PWM method comparator to be high (refer to block diagram).

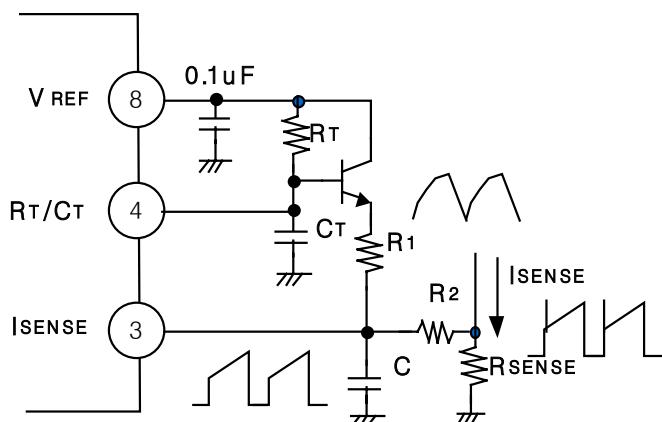

The PWM latch is reset dominant so that the output will remain low until the next clock cycle after the shutdown condition at pins 1 and/or 3 is removed. In one example, an externally latched shutdown may be accomplished by adding an SCR which turn off, allowing the SCR to reset.

6. Open Loop Test

High peak currents associated with capacitive leads necessitate careful grounding techniques. Timing and bypass capacitors should be connected close to Pin5 in a single point ground. The transistor and 5 k Ω potentiometer are used to sample the oscillator waveform and apply an adjustable ramp to Pin 3.

7. Slope Compensation

A fraction of the oscillator ramp can be resistively summed with the current sense signal to provide slope compensation for converters requiring duty cycle over 50%. Note that capacitor C₁ forms a filter with R₂ to suppress the leading edge switch spikes.
