

# SH7660 Hardware Manual

Renesas 32-Bit RISC Microcomputer HD6417660

www.DataSheet4U.con

### **Cautions**

Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

## Notes regarding these materials

- 1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
- 2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- 3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.

The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.

- Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (http://www.renesas.com).
- 4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- 5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- 6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
- 7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.

  Any diversion or reexport contrary to the export control laws and regulations of Japan and/or
  - Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- 8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

## **General Precautions on Handling of Product**

#### 1. Treatment of NC Pins

Note: Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are they are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

## 2. Treatment of Unused Input Pins

Note: Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

## 3. Processing before Initialization

Note: When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

#### 4. Prohibition of Access to Undefined or Reserved Addresses

Note: Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been be allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

## Configuration of This Manual

This manual comprises the following items:

- 1. General Precautions on Handling of Product
- 2. Configuration of This Manual
- 3. Preface
- 4. Contents
- 5. Overview
- 6. Description of Functional Modules
  - CPU and System-Control Modules
  - On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

- 7. List of Registers
- 8. Electrical Characteristics
- 9. Appendix
- 10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

## **Preface**

The SH7660 RISC (Reduced Instruction Set Computer) microcomputer includes a Renesas Technology original RISC CPU as its core, and the peripheral functions required to configure a system.

Target Users: This manual was written for users who will be using this LSI in the design of

application systems. Users of this manual are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

Objective: This manual was written to explain the hardware functions and electrical

characteristics of this LSI to the above users.

Refer to the SH-3/SH-3E/SH3-DSP Programming Manual for a detailed description

of the instruction set.

Notes on reading this manual:

Product names

The following products are covered in this manual.

#### **Product Classifications and Abbreviations**

Basic Classification	Product Code
SH7660	HD6417660

In order to understand the overall functions of the chip

Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, peripheral functions, and electrical characteristics.

In order to understand the details of the CPU's functions

Read the SH-3/SH-3E/SH3-DSP Programming Manual.

Rules: Register name: The following notation is used for cases when the same or a

similar function, e.g. serial communication, is implemented

on more than one channel:

XXX\_N (XXX is the register name and N is the channel

number)

Bit order: The MSB (most significant bit) is on the left and the LSB

(least significant bit) is on the right.

Number notation: Binary is B'xxxx, hexadecimal is H'xxxx, decimal is xxxx.

Signal notation: An overbar is added to a low-active signal:  $\overline{xxxx}$ 

Related Manuals: The latest versions of all related manuals are available from our web site.

Please ensure you have the latest versions of all documents you require.

# Section 1 Overview

#### 1.1 SH7660 Features

This LSI is a RISC (Reduced Instruction Set Computer) microcomputer that integrates a 32-bit RISC-type SuperH architecture CPU and digital signal processing (DSP) extended function as its core, together with 16-kbyte cache memory, 16-kbyte X/Y memory, and 128-kbyte U memory, as well as peripheral functions required for system configuration such as an interrupt controller.

High-speed data transfers can be performed by an on-chip direct memory access controller (DMAC) and a direct connection to various memories can be performed by the external memory access support function. Moreover, this LSI also includes powerful peripheral functions that are essential to system configuration, such as the USB (host/function), high-speed (921 kbits/s) asynchronous serial interface circuit, voice/audio CODEC serial interface circuit, and D/A converter.

Www.Da(This: LSI also supports the Bluetooth™ interface as one of peripheral functions and provides the Bluetooth protocol stack function including firmware up to the HCI layer as a standard function. Moreover, this LSI has extra processing power to perform the upper protocol stack and various application profiles to implement the whole Bluetooth baseband functions. The API is also provided to handle the protocol stack function below the HCI layer so that this Bluetooth interface can easily be handled like the conventional peripheral functions. This Bluetooth interface can be connected directly to the RF chip such as the HD157100NP or HD157102NP (manufactured by Renesas Technology).

Note: Bluetooth is a registered trademark of Bluetooth SIG, Inc., USA. Renesas Technology uses Bluetooth by entering into licensing agreements.

The features of this LSI are listed in table 1.1.

# Table 1.1 SH7660 Features

Item	Features
CPU	Renesas Technology Original SuperH architecture
	<ul> <li>Compatible with SH-1, SH-2 and SH-3 at object code level</li> </ul>
	32-bit internal data bus
	Supports various registers
	Sixteen 32-bit general registers (including eight 32-bit bank registers) Five 32-bit control registers
	Four 32-bit system registers
	Supports RISC-type instruction set
	Instruction length: 16-bit fixed length for improved code efficiency
	Load/store architecture
	Delayed branch instructions
	Instruction set suitable for C language
	Supports barrel shift instructions and multiply-and-accumulate instructions
	<ul> <li>Instruction execution time: One instruction/cycle for basic instructions</li> </ul>
	Logical address space: 4 Gbytes
	Five-stage pipeline
DSP unit	Mixture of 16-bit and 32-bit instructions
	32-/40-bit internal data bus
	Employs multiplier, ALU, and barrel shifter
	16-bit × 16-bit → 32-bit one cycle multiplier
	Employs large-capacity DSP data register files
	Six 32-bit data registers
	Two 40-bit data registers
	Extended harvard architecture for DSP data bus
	Two data buses
	One instruction bus
	Maximum four parallel operations: ALU, multiply, and two load or store  True addressing units to proport addresses for two marrows again.
	<ul> <li>Two addressing units to generate addresses for two memory access</li> <li>DSP data addressing modes: Increment and indexing (with or without</li> </ul>
	modulo addressing)
	<ul> <li>Zero-overhead repeat loop control</li> <li>Conditional execution instructions</li> </ul>
	User DSP mode and privileged DSP mode

Item	Features	
Cache memory	16-kbyte cache, unified of instructions and data	
	• 256 entries, 4-way set associative, and 16-byte block length	
	Write-back, write-through, and LRU replacement algorithm	
	1-stage write-back buffer	
	Maximum 2 ways can be protected	
X/Y memory	Three independent read/write ports	
	8-/16-/32-bit access from the CPU	
	Maximum two 16-bit accesses from the DSP	
	8-/16-/32-bit access from the DMAC	
	8-/32-bit access from the USBH	
	A total of 16 kbytes (4 kbytes × 4)	
	No interrupt requests	
	No DMA transfer requests (accessible as a transfer source or destination)	
U memory	Two independent read/write ports	
	8-/16-/32-bit access from the CPU	
	16-/32-bit access from the DSP	
	8-/16-/32-bit access from the DMAC	
	8-/32-bit access from the USBH	
	As large as 128-kbyte memory	
	No interrupt requests	
	No DMA transfer requests (accessible as a transfer source or destination)	
Interrupt	Five external interrupt pins (NMI, IRQ4 to IRQ2, IRQ0)	
controller (INTC)	One interrupt request output pin (IRQOUT)	
	On-chip peripheral interrupt: Priority is independently selected for each module	
	Selection of falling/rising edge sense and high/low level sense	

RENESAS

ltem	Features
Bus state	• Physical address space is divided into three areas: Area 0, area 3, area 4;
controller (BSC)	each a maximum of 16 Mbytes
	The following features are settable for each area:
	Bus size (8 or 16 bits); The supported bus size may differ for each area
	Number of access wait cycles (Numbers of wait-state cycles during reading and writing are independently selectable for some areas.)
	Setting of idle wait cycles (for the same area or different area)
	Specifying the memory to be connected to each area allows direct connection to SRAM, SRAM with byte selection, SDRAM, or burst ROM
	Outputs chip select signals ( $\overline{CS0}$ , $\overline{CS3}$ , $\overline{CS4}$ ) for corresponding area (Can turned by the program $\overline{CSn}$ assert/negate timing.)
	SDRAM refresh function
	Auto-refresh and self-refresh modes
	SDRAM burst access function
-t-Obt411	Big endian or little endian can be set.
Direct memory	Four channels (for one channel, external requests can be accepted)
access controller (DMAC)	Burst mode and cycle-steal mode
(DIVIAC)	Intermittent cycle-steal mode
Clock pulse	Clocks can be input from an external pin (EXTAL or CKIO) or crystal unit
generator (CPG)	Three clocks generated:
	Internal clock: 120 MHz
	Bus clock: 60 MHz
	Peripheral clock: 30 MHz
	Supports power-down modes:
	Software standby mode
	Sleep mode
	Module standby mode
	Three clock modes (PLL1 and PLL2 multiplication ratio, clock, and crystal
	unit can be selected)
	One frequency-divider mode
Watchdog timer	One-channel watchdog timer
(WDT)	Watchdog timer mode and interval timer mode can be selected
	In interval timer mode, interrupts can be generated

Item	Features
Timer unit (TMU)	Three channels of 32-bit timer
	Four input clocks can be selected for each channel counter
	32-bit down counter of the auto-reload type
	<ul> <li>On-chip prescaling by Pφ</li> </ul>
_	• Interrupt requests: Interrupt requests are generated by underflow of 32-bit down counter
Serial I/O with	One channel
FIFO (SIOF)	16-stage 32-bit FIFOs (independent for reception and transmission)
	8-/16-/16-bit stereo-audio input/output supported
	<ul> <li>Synchronization method: Frame synchronized pulse and switching between left and right channels</li> </ul>
	Supports a CODEC control data interface
	• Can be connected to linear, audio, A-Law, or μ-Law CODEC chip
ota Cha at 41 Lagra	Supports master and slave modes
ataSheet4U.com	<ul> <li>Sampling rate clock can be generated from Pφ or be input from external pin (max. 48 kHz)</li> </ul>
	<ul> <li>On-chip prescaler from Pφ</li> </ul>
	Module standby function
	Capable of interrupt requests and DMAC requests
Serial	Two channels
communication	Supports asynchronous mode and clocked synchronous mode
interface with FIFO	64-byte transmit/receive FIFOs
(SCIF0, SCIF1)	High-speed UART
	Supports CTS/RTS
	<ul> <li>On-chip prescaler from Pφ</li> </ul>
	Capable of interrupt requests and DMAC requests
Boot function	Normal mode or boot mode at a power-on reset
(BOOT)	Automatic fetching of initial write program from SCIF0
	Downloading of program to on-chip memory (U memory)
	Auto-running function of downloaded program

RENESAS

Item	Features		
USB host	Register set conforming to OHCI version 1.0		
controller (USBH)	Conforms to USB 1.1		
	Supports 127 endpoints		
	Supports control/bulk/interrupt/isochronous modes		
	Bus master controller		
	One-port USB transceiver (sharing with USB function controller)		
	Selectable module input clock: 48-MHz external input or on-chip DLL		
	Capable of issuing interrupt requests		
USB function	Conforms to USB 1.1		
controller (USBF)	One-port USB transceiver (sharing with USB host controller)		
	Supports six endpoints, the number of endpoints is selectable		
	Supports isochronous, totally 2 endpoints		
	Supports control (endpoint 0)/bulk (2 endpoints)/interrupt (1 endpoint)		
	The USB standard commands are supported, and class and vendor		
	commands are handled by firmware		
	On-chip FIFO buffer for endpoints (bulk, isochronous: 128 bytes/endpoint)		
	Selectable module input clock: 48-MHz external input or on-chip DLL		
	Capable of issuing interrupt requests and DMAC requests		
Bluetooth	Supports Bluetooth version 1.1		
interface (BT)	• Supports direct interface with the HD157100NP or HD157102NP (Renesas) RF IC		
	Supports direct interface with the STLC7550 or MC145483 voice CODEC IC		
	<ul> <li>Supports four voice CODEC formats (A-law/μ-law/CVSD/linear PCM)</li> </ul>		
	Supports ACL and SCO links (SCI over HCI possible)		
	<ul> <li>Frequency hopping within 79 channels as a form of spread-spectrum modulation</li> </ul>		
	<ul> <li>Use of the 32.768-kHz clock for RTC (Realtime Clock) as the clock for power-down mode</li> </ul>		
	Selectable clock for power-down mode: Crystal oscillator mode or external direct input mode		
	Supports three power-down modes: Hold/sniff/park		
D/A converter	Two channels of 8 bit D/A converters		
(DAC)	Output range: 0 to AVcc		
I/O port/pin function controller (PFC)	Bitwise selection of input/output		

Item	Features	
User break controller (UBC)	Address, data value, access type, and data size are available for setting as break conditions	
	Supports the sequential break function	
	Two break channels	
User debugging	Supports the E10A emulator	
interface (H-UDI)	Realtime branch trace	
	1-kbyte of on-chip RAM for executing the high-speed emulation program	
Package	• 208-pin BGA (pin pitch: 0.65 mm)	
Power-supply	• I/O: 3.0 to 3.6 V (some parts: 2.7 to 3.0 V)	
voltage	• Internal: on-chip regulator provides, or 1.4 to 1.6 V external power supply	
	can be selected.	
Operating	• -40°C to +85°C (except USB)	
temperature range	• -20°C to +85°C (for USB only)	

- www.DaNôtes:41. This LSI does not support the MMU and TLB functions, therefore, the LDTLB instruction provided by the SH-3 CPU is not available.
  - 2. Since the on-chip AUD and ASERAM modules are used for debugging, related descriptions are omitted in this manual. For details, refer to the user's manual related to development tools.

# 1.2 Block Diagram

Figure 1.1 shows an internal block diagram of the SH7660.

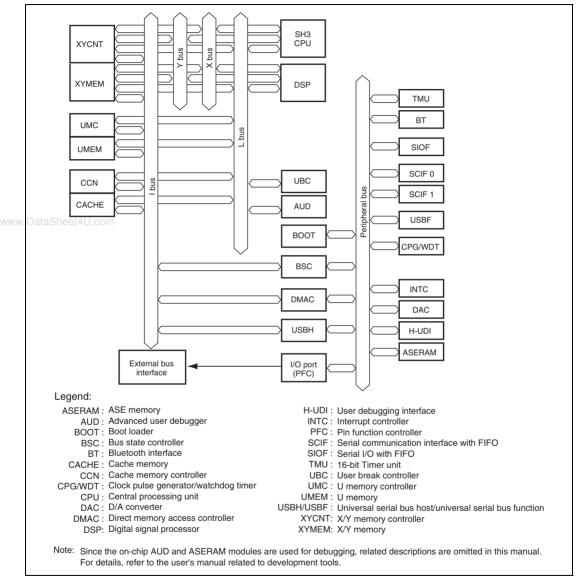

Figure 1.1 Block Diagram of SH7660

## 1.3 Pin Assignment

Figure 1.2 shows the pin assignment. Table 1.2 shows pin functions and initial values.

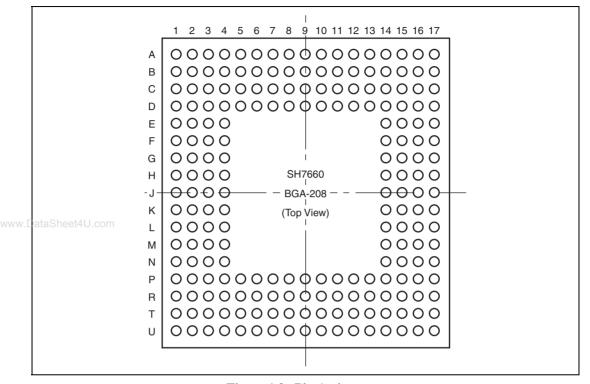

Figure 1.2 Pin Assignment

**Table 1.2** Pin Functions and Initial Values

Pin No.	Pin Name	Description
A1	PTH4/SCIF1_CTS	Port H/CTS input for SCIF1
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
A2	NMI	Nonmaskable interrupt request
		When this pin is not used, it should be fixed to high.
A3	PTB1/IRQ2	Port B/external interrupt request input
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
A4	RTCSEL0	Test pin
		This pin must be fixed to low.
A5	NC	Reserved
ataSheet4		This pin should be open.
A6	NC	Reserved
		This pin should be open.
A7	AVss (DAC)	Analog power supply for D/A converter (DAC) (0 V)
A8	XTAL	Crystal unit pin
A9	EXTAL	External clock input/crystal unit pin
A10	EXTAL2	External clock input/crystal unit pin for Bluetooth power- down state
		When RTCSEL0 = high, this pin enters the non-active state.
A11	RDI_TXTRDATA*1	Transmit/receive data I/O for RF IC
		The initial state is output.
A12	Vss_28	Power supply for I/O pins with RF IC (0 V)
A13	RDI_REFCLK_IN*1	Clock input for data I/O with RF IC
		This pin is always input.
A14	RCI_SPI_TXRX*1	SPI serial data I/O with RF IC
		The initial state is output.
A15	USB_N	D- I/O for on-chip USB transceiver
		The initial state is Hi-Z.
A16	USB_P	D+ I/O for on-chip USB transceiver
		The initial state is Hi-Z.
A17	AVss (USB)	Analog power supply for USB transceiver (0 V)

www.DataSheet4U.com

Pin No.	Pin Name	Description
B1	NC	Reserved
		This pin should be open.
B2	ASEMD0	ASE mode control input
		This pin should be fixed to high in the normal state.
B3	PTG0/SCIF0_SCK/IRQ3	Port G/clock I/O for SCIF0/external interrupt request input
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
B4	RREF	Test pin
		This pin should be pulled-up.
B5	NC	Reserved
		This pin should be open.
B6	Vss (DLL)	Power supply for internal regulator (DLL) (0 V)
Dat <b>B7</b> heet4U.	colDV0	D/A converter (DAC) output (channel 0)
B8	Vcc (I/O)	Power supply for I/O (3.3 V)
B9	Vss	Power supply (0 V)
B10	XTAL2	Crystal unit pin for Bluetooth power-down state
		When RTCSEL0 = high, this pin enters the non-active state.
B11	RDI_RXBDW_OUT*1	Packet control output for RF IC
B12	Vcc_28	Power supply for I/O pin with RF IC (2.8 V/3.3 V)
B13	RCI_SPI_CLK*1	SPI interface clock output with RF IC
B14	NC	Reserved
		This pin should be open.
B15	NC	Reserved
		This pin should be open.
B16	NC	Reserved
		This pin should be open.
B17	NC	Reserved
		This pin should be open.
C1	PTH1/SCIF1_TxD	Port H/transmit data output for SCIF1
		This pin is fixed to input and enters the output Hi-Z state in the initial state.

Pin No.	Pin Name	Description
C2	PTH2/SCIF1_RxD	Port H/receive data input for SCIF1
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
C3	PTH3/SCIF1_RTS	Port H/RTS output for SCIF1
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
C4	PTB0/IRQ0	Port B/external interrupt request input
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
C5	Vss (SREG)	Power supply for internal regulator (sub) (0 V)
C6	V <sub>DD</sub> (DLL)	Power-supply output from internal regulator / power-supply input (DLL) (1.5 V)
Da <b>C7</b> Sheet4L	J.o <b>DA1</b>	D/A converter (DAC) output (channel 1)
C8	Vss	Power supply (0 V)
C9	NC	Reserved
		This pin should be open.
C10	Vss	Power supply (0 V)
C11	RDI_CTRL3*1	Strobe output for enabling RF-IC oscillator
C12	Vss_28	Power supply for I/O pin with RF IC (0 V)
C13	RCI_SPI_ENB*1	SPI interface enable output with RF IC
C14	AVcc (USB)	Analog power supply for USB transceiver (3.3 V)
C15	NC	Reserved
		This pin should be open.
C16	UCLK	External clock input for USB
		When initialized, the internal DLL clock is valid and this pin is internally fixed to input.
C17	USB_OVR_CRNT/ USB_VBUS	Over current detection input for USB/USB-cable connection monitor input
		Even if this pin is not used, this pin should be driven by an appropriate level.
D1	PTG2/SCIF0_RxD	Port G/receive data input for SCIF0
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.

Pin No.	Pin Name	Description
D2	PTG3/SCIF0_ RTS	Port G/RTS output for SCIF0
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
D3	PTG4/SCIF0_ CTS	Port G/CTS input for SCIF0
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
D4	PTH0/SCIF1_SCK/IRQ4	Port H/clock I/O for SCIF1/external interrupt request input
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
D5	Vcc (SREG)	Power supply for internal regulator (sub) (3.3 V)
D6	Vcc (DLL)	Power supply for internal regulator (DLL) (3.3 V)
it <b>D7</b> neet4U.co	Vss	Power supply (0 V)
D8	AVcc (DAC)	Analog power supply for D/A converter (DAC) (3.3 V)
D9	Vcc (I/O)	Power supply for I/O (3.3 V)
D10	NC	Reserved
		This pin should be open.
D11	RDI_CTRL4*1	Reset control for RF IC and power-down control output
D12	Vcc_28	Power supply for I/O pin with RF IC (2.8 V/3.3 V)
D13	RESETP	Power-on reset input
D14	USB_PWR_EN/ USB_PULLUP	USB power-supply application enable control output/pull- up control output for USB
		The initial state is low-level output.
D15	Vcc (PLL)	Power supply for internal regulator (PLL1/PLL2) (3.3 V)
D16	V <sub>DD</sub> (PLL)	Power supply output from internal regulator/power- supply input (PLL1/PLL2) (1.5 V)
D17	Vss (PLL)	Power supply for internal regulator (PLL1/PLL2) (0 V)
E1	PTA6/SIOF_SS2	Port A/SPI mode slave device select for SIOF
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
E2	PTG1/SCIF0_TxD	Port G/transmit data output for SCIF0
		This pin is fixed to input and enters the output Hi-Z state in the initial state.
E3	Vss	Power supply (0 V)
		www.DataSheet4U.com
		Rev. 1.00, 02/04, page 13 of 804

Pin No.	Pin Name	Description
E4	Vcc (I/O)	Power supply for I/O (3.3 V)
E14	Vcc (internal)	Power supply for internal regulator (3.3 V)
E15	V <sub>DD</sub>	Power-supply output from internal regulator/power-supply input (1.5 V)
E16	Vss	Power supply (0 V)
E17	CKIO	System clock I/O
F1	PTA5/SIOF_SS1	Port A/SPI mode slave device select for SIOF
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
F2	Vss	Power supply (0 V)
F3	V <sub>DD</sub>	Power-supply output from internal regulator/power-supply input (1.5 V)
F4	Vcc (internal)	Power supply for internal regulator (3.3 V)
Data <b>4</b> heet4U.	√cc (I/O)	Power supply for I/O (3.3 V)
F15	Vss	Power supply (0 V)
F16	NC	Reserved
		This pin should be open.
F17	MD5	Endian set input
G1	PTA2/SIOF_RXD (MISO)	Port A/receive data input for SIOF
		Though this pin is fixed to input and enters the output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
G2	PTA3/SIOF_SYNC (SIOF_SS0)	Port A/frame synchronization signal output for SIOF (SPI mode slave device select for SIOF)
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
G3	PTA4/SIOF_SCK (SCK)	Port A/serial clock I/O for SIOF
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
G4	NC	Reserved
		This pin should be open.
G14	MD2	Clock mode set input
G15	MD1	Clock mode set input

Pin No.	Pin Name	Description
G16	PTE6/RDI_CTRL2* <sup>1</sup> /IRQOUT	Port E/external power amplifier control output for RF IC /IRQOUT
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
G17	PTE0 /VCI_CODEC_PWRDWN*²	Port E/power-down control output for voice CODEC IC /DMA transfer end flag output
	/TEND	Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
H1	TEST_REG	Built-in regulator selection pin. The built-in power supply regulator is used when this pin is high, external power input is used when this pin is low for the internal power (VDD=1.5V).
H2	NC	Reserved
ata Shaat 4. L	222	This pin should be open.
H3	PTA0/SIOF_MCLK	Port A/master clock input for SIOF
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
H4	PTA1/SIOF_TXD (MOSI)	Port A/transmit data output for SIOF
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
H14	Vcc (internal)	Power supply for internal regulator (3.3 V)
H15	V <sub>DD</sub>	Power-supply output from internal regulator/power-supply input (1.5 V)
H16	Vss	Power supply (0 V)
H17	PTE1/VCI_SCO_TX*2/DACK	Port E/transmit data input from voice CODEC IC /DMA transfer request accept
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
J1	TRST	H-UDI reset input
		This pin is internally pulled up. When a boundary scan function is not used in normal mode (ASEMD0 = high), this pin should be fixed to low.
J2	ASEBRKAK	ASE break acknowledge output
J3	TDO	H-UDI data output

Rev. 1.00, 02/04, page 15 of 804

Pin No.	Pin Name	Description
J4	TEST	Test input
		This pin should always be fixed to high.
J14	Vcc (I/O)	Power supply for I/O (3.3 V)
J15	PTE2/VCI_SCO_RX* <sup>2</sup> /DREQ	Port E/receive data output to voice CODEC IC /DMA transfer request input
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
J16	PTE4 /VCI_SCO_SYNC_OUT* <sup>2</sup>	Port E/frame synchronization signal output for voice CODEC IC/bus mastership request input
	/BREQ	The bus mastership request input is valid in the initial state.
J17	PTE3 /VCI_SCO_CLK_OUT* <sup>2</sup>	Port E/clock output for voice CODEC IC/bus release acknowledge output
DataSheet4l	/BACK J.com	The bus release acknowledge output is valid in the initial state.
K1	TDI	H-UDI test data input
		This pin is internally pulled up.
K2	TCK	H-UDI clock input
		This pin is internally pulled up.
K3	Vss	Power supply (0 V)
K4	Vcc (I/O)	Power supply for I/O (3.3 V)
K14	AUDATA3	AUD data bus (bit 3) output
K15	AUDSYNC	AUD synchronization signal output
K16	PTE5/VCI_HWC* <sup>2</sup>	Port E/operating mode select output for voice CODEC IC
		Though this pin is fixed to input and enters output Hi-Z state in the initial state, the internal pull-up MOS is turned on.
K17	Vss	Power supply (0 V)
L1	TMS	H-UDI test mode switch
		This pin is internally pulled up.
L2	Vss	Power supply (0 V)
L3	$V_{\scriptscriptstyle DD}$	Power-supply output from internal regulator/Power-supply input (1.5 V)
L4	Vcc (internal)	Power supply for internal regulator (3.3 V)
L14	Vcc (I/O)	Power supply for I/O (3.3 V)

Pin No.	Pin Name	Description
L15	Vss	Power supply (0 V)
L16	AUDATA1	AUD data bus (bit 1) output
L17	AUDATA2	AUD data bus (bit 2) output
M1	NC	Reserved
		This pin should be open.
M2	BOOT_E	Boot mode enable control input
		This pin is internally pulled up.
МЗ	CS0	Chip select 0 signal output
M4	CS3	Chip select 3 signal output
M14	PTB7/BS	Port B/bus cycle start signal output
		The bus cycle start signal output is valid in the initial state.
M15	RD	Read strobe signal output
M16 <sub>et4U</sub>	.co.AUDCK	AUD clock output
M17	AUDATA0	AUD data bus (bit 0) output
N1	CS4	Chip select 4 signal output
N2	D0	Data bus (bit 0)
N3	D1	Data bus (bit 1)
N4	D2	Data bus (bit 2)
N14	Vcc (internal)	Power supply for internal regulator (3.3 V)
N15	V <sub>DD</sub>	Power-supply output from internal regulator/Power-supply input (1.5 V)
N16	Vss	Power supply (0 V)
N17	PTB6/REFOUT	Port B/bus release request output
		The bus release request output is valid in the initial state.
P1	D3	Data bus (bit 3)
P2	D4	Data bus (bit 4)
P3	Vcc (I/O)	Power supply for I/O (3.3 V)
P4	D5	Data bus (bit 5)
P5	D13	Data bus (bit 13)
P6	Vcc (I/O)	Power supply for I/O (3.3 V)
P7	A3	Address bus (bit 3)
P8	Vcc (I/O)	Power supply for I/O (3.3 V)
P9	A8	Address bus (bit 8)

Pin No.	Pin Name	Description
P10	Vcc (I/O)	Power supply for I/O (3.3 V)
P11	A15	Address bus (bit 15)
P12	Vcc (I/O)	Power supply for I/O (3.3 V)
P13	PTD3/A21	Port D/address bus (bit 21)
		The A21 output is valid in the initial state.
P14	PTB4/RAS	Port B/RAS (SDRAM) output
		The $\overline{RAS}$ output is valid in the initial state.
P15	Vcc (I/O)	Power supply for I/O (3.3 V)
P16	Vss	Power supply (0 V)
P17	WAIT	Hardware wait request
		This pin is internally pulled up.
R1	Vss	Power supply (0 V)
R2 ataSheet4	REG_PD_MAIN  J.com	This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the internal power supply
		regulator is used.
R3	D10	Data bus (bit 10)
R4	Vcc (I/O)	Power supply for I/O (3.3 V)
R5	D14	Data bus (bit 14)
R6	Vss	Power supply (0 V)
R7	A4	Address bus (bit 4)
R8	Vss	Power supply (0 V)
R9	A11	Address bus (bit 11)
R10	REG_PD_BGR	This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the internal power supply regulator is used.
R11	A14	Address bus (bit 14)
R12	A18	Address bus (bit 18)
R13	PTD2/A20	Port D/address bus (bit 20)
		The A20 output is valid in the initial state.
R14	Vcc (I/O)	Power supply for I/O (3.3 V)
R15	PTB2/CKE	Port B/clock enable (SDRAM) output
		The CKE output is valid in the initial state.
R16	WE0/DQM0	D7 to D0 select signal/DQM (SDRAM) output
R17	WE1/DQM1	D15 to D8 select signal/DQM (SDRAM) output

Pin No.	Pin Name	Description
T1	D6	Data bus (bit 6)
T2	D7	Data bus (bit 7)
T3	NC	Reserved
		This pin should be open.
T4	D11	Data bus (bit 11)
T5	D15	Data bus (bit 15)
T6	A1	Address bus (bit 1)
T7	A5	Address bus (bit 5)
T8	REG_PD_VREF	This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the internal power supply regulator is used.
T9	A9	Address bus (bit 9)
T10	NC	Reserved
ataSheet4U		This pin should be open.
T11	A13	Address bus (bit 13)
T12	A17	Address bus (bit 17)
T13	PTD1/A19	Port D/address bus (bit 19)
		The A19 output is valid in the initial state.
T14	PTD5/A23	Port D/address bus (bit 23)
		The A23 output is valid in the initial state.
T15	PTB5/RD/WR	Port B/read/write output
		The read/write output is valid in the initial state.
T16	VBB	Test pin
		This pin should be connected to Vss.
T17	NC	Reserved
		This pin should be open.
U1	D8	Data bus (bit 8)
U2	D9	Data bus (bit 9)
U3	Vss	Power supply (0 V)
U4	D12	Data bus (bit 12)
U5	PTD0/A0	Port D/address bus (bit 0)
		The A0 output is valid in the initial state.
U6	A2	Address bus (bit 2)
U7	A6	Address bus (bit 6)

Pin No.	Pin Name	Description
U8	A7	Address bus (bit 7)
U9	A10	Address bus (bit 10)
U10	A12	Address bus (bit 12)
U11	Vss	Power supply (0 V)
U12	A16	Address bus (bit 16)
U13	Vss	Power supply (0 V)
U14	PTD4/A22	Port D/address bus (bit 22)
		The A22 output is valid in the initial state.
U15	Vss	Power supply (0 V)
U16	PTB3/CAS	Port B/CAS (SDRAM) output
		The CAS output is valid in the initial state.
U17	VBBENB	Test pin
		This pin should be connected to Vss.

Notes: 11. These pins are connected to the RF IC. For details on the connection, refer to section 21, Bluetooth Interface (BT).

<sup>2.</sup> These pins are connected to the voice CODEC IC. For details on the connection, refer to section 21, Bluetooth Interface (BT).

# 1.4 Pin Functions

Table 1.3 lists the pin functions.

**Table 1.3 Pin Functions** 

Classification	Symbol	I/O	Name	Function
Power supply	VDD*1	Output/ Input	Power supply	Power output of the built-in regulator, or power input from an external power supply (for internal circuit). A pin function is specified with the TEST_REG pin.
	Vcc (internal)	Input	Power supply	Power supply for internal regulator. Connect all Vcc pins to the system power supply. There will be no operation if any pins are open.
ataSheet4U.com	Vcc (I/O)	Input	Power supply	Power supply for I/O pins. Connect all Vcc pins to the system power supply. There will be no operation if any pins are open.
	Vss	Input	Ground	Ground pin. Connect all Vss pins to the system power supply (0 V). There will be no operation if any pins are open.
	TEST_REG	Input	Power supply selection	Built-in regulator selection pin. The built-in power supply regulator is used when this pin is high, external power input is used when this pin is low for the internal power (VDD=1.5V). The level of this pin should not be changed during operation
	REG_PD_MAIN	Input/NC	Power supply control	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the built-in power supply regulator is used.
	REG_PD_ BGR	Input/NC	Power supply control	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the built-in power supply regulator is used.

Classification	Symbol	I/O	Name	Function
Power supply	REG_PD_VREF	Input/NC	Power supply control	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD=1.5V). This pin should be open when the built-in power supply regulator is used.
Clock	Vcc (PLL)	Input	PLL1/PLL2 power supply	Power supply for on-chip PLL1/PLL2 oscillator
	VDD (PLL)* <sup>1</sup>	Output/ Input	Power supply	Power output of the built-in regulator for PLL1/PLL2 oscillator, or power input from an external power supply. A pin function is specified with the TEST_REG pin.
	Vss (PLL)	Input	PLL1/PLL2 ground	Ground pin for on-chip PLL1/PLL2 oscillator
.DataSheet4U.com	EXTAL	Input	Crystal input (clock input)	For connection to the crystal resonator. Also, this pin can input external clocks.
				For connection to the crystal resonator and connection of the input of external clocks, refer to section 11, Clock Pulse Generator (CPG).
	XTAL	Output	Crystal output	For connection to the crystal resonator.
				For connection to the crystal resonator and connection of the input of external clocks, refer to section 11, Clock Pulse Generator (CPG).
	CKIO	I/O	Clock I/O	Supplies system clocks to external devices or used for external clock input.
Operating mode control	MD5, MD2, MD1	Input	Mode control	Sets the operating mode. The level on these pins should not be changed during operation.
	IVID I			MD2 and MD1 set the clock mode and MD5 sets the endian.

Classification	Symbol	I/O	Name	Function
System control	RESETP	Input	Power-on reset	When this pin goes low, the system enters the power-on reset state.
	BOOT_E	Input	Boot control	Boot mode enable control input.
				When this pin goes low at a power- on reset, the system enters the boot mode and runs the boot loader after reset processing. When this pin goes high at a power-on reset, the normal reset sequence is executed.
	BREQ	Input	Bus mastership request	This pin is set to low when an external device requests the bus mastership release.
DataSheet4U.com	BACK	Output	Bus mastership request acknowledge	Indicates that bus mastership is externally released. A device which has output the BREQ signal knows that the bus mastership is acquired by receiving the BACK signal.
Interrupts	NMI	Input	Nonmaskable interrupt request	Nonmaskable interrupt request pin. This pin should be fixed to high when not in use.
	IRQ4 to IRQ2,	Input	Interrupt	Maskable interrupt request pins.
	IRQ0		requests 4 to 2, 0	Selectable as level input or edge input. The rising edge, falling edge, and both edges are selectable as edges.
	ĪRQOUT	Output	Bus mastership request	Notifies an external device of interrupt source occurrence.
Address bus	A23 to A0	Output	Address bus	Outputs addresses.
Data bus	D15 to D0	I/O	Data bus	16-bit bidirectional bus
Bus control	CS0, CS3, CS4	Output	Chip select 0, 3, 4	Chip select signal for external memory or devices
	RD	Output	Read	Indicates reading of data from external devices.
	RD/WR	Output	Read/write	Read/write signal pin
	BS	Output	Bus start	Bus cycle start signal pin
	WE1	Output	Write upper bits	Indicates that bits 15 to 8 of the data in the external memory or device are being written.

Classification	Symbol	I/O	Name	Function
Bus control	WE0	Output	Write lower bits	Indicates that bits 7 to 0 of the data in the external memory or device are being written.
	CAS	Output	Data enable	CAS signal of SDRAM
	RAS	Output	Data enable	RAS signal of SDRAM
	CKE	Output	Clock enable	Clock enable signal pin of SDRAM
	DQM1	Output	DQ mask	Indicates that bits 15 to 8 of the data in SDRAM are selected.
	DQM0	Output	DQ mask	Indicates that bits 7 to 0 of the data in SDRAM are selected.
	REFOUT	Output	Bus release request	Indicates that a refresh request has occurred during bus mastership release.
.DataSheet4U.com	WAIT	Input	Wait	Inserts a wait cycle into the bus cycles during access to the external space.
Direct memory access controller	DREQ	Input	DMA transfer request	Input pin for an external DMA transfer request
(DMAC)	DACK	Output	DMA transfer request acceptance	Output pin for external DMA transfer request acceptance
	TEND	Output	DMA transfer end	Indicates that DMA transfer ends.
Serial I/O with FIFO	SIOF_TXD (MOSI)	Output	Transmit data	Transmit data pin
(SIOF)	SIOF_RXD (MISO)	Input	Receive data	Receive data pin
	SIOF_SCK (SCK)	I/O	Serial clock	Clock I/O pin
	SIOF_MCLK	Input	Master clock	Master clock input pin
	SIOF_SYNC	I/O	Frame	Frame synchronization signal pin
	(SIOF_SSO)		synchronization signal (slave device 0 select)	(In SPI mode, selects the slave device 0.)
	SIOF_SS1	Output	Slave device 1 select	In SPI mode, selects the slave device 1.
	SIOF_SS2	Output	Slave device 2 select	In SPI mode, selects the slave device 2.

	Serial communication interface with	SCIF0_TxD,	Output		
	interface with	SCIF1_TxD	Output	Transmit data	Transmit data pin
	FIFO (SCIF0, SCIF1)	SCIF0_RxD, SCIF1_RxD	Input	Receive data	Receive data pin
	(3311 0, 3311 1)	SCIF0_SCK, SCIF1_SCK	I/O	Serial clock	Clock I/O pin
		SCIF0_RTS, SCIF1_RTS	Output	Transmit request	Modem control pin
		SCIF0_CTS, SCIF1_CTS	Input	Transmit enable	Modem control pin
_	USB	UCLK	Input	USB clock	USB clock input pin (48-MHz input)
		USB_PWR_EN/ USB_PULLUP	Output	USB power supply control	Host: USB power supply application enable control
					Function: USB pull-up control
		USB_OVR_CR	Input	USB power	Host: Over current detection
	aSheet4U.com	NT/USB_VBUS		supply detection	Function: USB-cable connection monitor pin
		USB_N	I/O	D- I/O	D- I/O for on-chip USB transceiver
		USB_P	I/O	D+ I/O	D+ I/O for on-chip USB transceiver
		AVcc (USB)	Input	Analog power supply for USB transceiver	Analog power supply pin for USB transceiver
		AVss (USB)	Input	Analog ground for USB	Analog ground pin for USB transceiver
				transceiver	Connect to the system ground (Vss).
		Vcc (DLL)	Input	3.3-V power supply for USB clock	Power supply pin for the 48-MHz clock multiplication circuit of the USB
				multiplication circuit	Connect to the system power supply (Vcc).
		VDD (DLL)* <sup>1</sup>	Output/ Input	Power supply	Power output of the built-in regulator for 48MHz clock frequency multiplier circuit of USB, or power input from an external power supply. A pin function is specified with the TEST_REG pin.
		Vss (DLL)	Input	Ground for USB clock multiplication	multiplication circuit of the USB
_				circuit	Connect to the system ground (Vss).

Classification	Symbol	I/O	Name	Function
Bluetooth interface (BT)	RDI_ TXTRDATA* <sup>2</sup>	I/O	Data bus for transmission/ reception	Bus for data transmission/reception with the RF IC
	RDI_RXBDW_ OUT* <sup>2</sup>	Output	Packet control	Signal for notifying the RF IC of the packet processing state of the BT
	RDI_REFCLK_ IN* <sup>2</sup>	Input	BT clock input	Input the BT operating clock.
	RDI_CTRL2*2	Output	RF IC control 2	Used for external power amplifier control when supporting class 1.
	RDI_CTRL3*2	Output	RF IC control 3	Strobe signal for enabling the RF IC oscillator
	RDI_CTRL4*2	Output	RF IC control 4	Reset control and power-down control output for RF IC
	RCI_SPI_CLK*2	Output	SPI clock	Serial interface clock
DataSheet4U.com	RCI_SPI_ TXRX* <sup>2</sup>	I/O	SPI data	Serial interface data
	RCI_SPI_ENB*2	Output	SPI enable	Serial interface enable signal
	VCI_SCO_ CLK_OUT*3	Output	VCI clock	Supplies a clock to the voice CODEC IC.
	VCI_SCO_ SYNC_OUT*3	Output	VCI synchronization	Supplies a frame-synchronization signal to the voice CODEC IC.
	VCI_SCO_TX*3	Input	SCO transmit data	Inputs SCO data to be transmitted from the voice CODEC IC.
	VCI_SCO_RX*3	Output	SCO receive data	Outputs received SCO data to the voice CODEC IC.
	VCI_HWC*3	Output	VCI mode select	Selects operating mode of the voice CODEC IC (STLC7550).
	VCI_CODEC_ PWRDWN*3	Output	VCI power down	Controls power-down for the voice CODEC IC.
	RTCSEL0	Input	Test pin	Test pin
				This pin should be fixed to low.
	RREF	Input	Test pin	Test pin
				This pin should be pulled-up.
	EXTAL2	Input	Crystal resonator	For connection to a crystal resonator for a low-power clock.
	XTAL2	Output	connection for low-power clock	When RTCSEL0 = high, these pins

Classification	Symbol	I/O	Name	Function
Bluetooth interface (BT)	Vcc_28	Input	Power supply	Power supply pin for the RF-IC connection pin
				The same level should be supplied as the RF IC.
	Vss_28	Input	Ground	Ground pin for the RF-IC connection pin
D/A converter (DAC)	DA1, DA0	Output	Analog output pin	Analog output pin for the D/A converter
	AVcc (DAC)	Input	D/A analog power supply	Power supply pin for the D/A converter. When the D/A converter is not in use, connect this pin to the port power supply (Vcc).
	AVss (DAC)	Input	D/A analog ground	Ground pin for the D/A converter. Connect this pin to the system power supply (Vss).
I/O port ataSheet4U.com	PTA6 to PTA0	I/O	General port	7-bit general I/O port pin
ataSneet4U.com	PTB7 to PTB0	I/O	General port	8-bit general I/O port pin
	PTD5 to PTD0	I/O	General port	6-bit general I/O port pin
	PTE6 to PTE0	I/O	General port	7-bit general I/O port pin
	PTG4 to PTG0	I/O	General port	5-bit general I/O port pin
	PTH4 to PTH0	I/O	General port	5-bit general I/O port pin
User debugging interface (H-UDI)	TCK	Input	Test clock	Test-clock input pin
	TMS	Input	Test mode select	Inputs the test-mode select signal.
	TDI	Input	Test data input	Serial input pin for instructions and data
	TDO	Output	Test data output	Serial output pin for instructions and data
	TRST	Input	Test reset	Initialization-signal input pin
Advanced user debugger (AUD)	AUDATA3 to AUDATA0	Output	AUD data	Destination-address output pin for branch instruction
	AUDCK	Output	AUD clock	Synchronization clock output pin
	AUDSYNC	Output	AUD synchronization signal	Data start-position acknowledge- signal output pin

Classification	Symbol	I/O	Name	Function
E10A interface	ASEBRKAK	Output	Break mode acknowledge	Indicates that the E10A emulator has entered its break mode.
				For the connection with the E10A, refer to the SH7660 E10A Emulator User's Manual (tentative title).
	ASEMD0	Input	ASE mode	Sets the ASE mode.

- Notes: 1. VDD, VDD (PLL), and VDD (DLL) should not connect mutually in the short distance, should separate as much as possible, and give the noise measures.
  - 2. These pins are connected to the RF IC. For details on the connection, refer to section 21, Bluetooth Interface (BT).
  - 3. These pins are connected to the voice CODEC IC. For details on the connection, refer to section 21, Bluetooth Interface (BT).

# Section 2 CPU

## 2.1 Processing States and Processing Modes

### 2.1.1 Processing States

This LSI supports four types of processing states: a reset state, an exception handling state, a program execution state, and a power-down state, according to the CPU processing states.

**Reset State:** In the reset state, the CPU is reset. The LSI supports two types of resets: power-on reset and manual reset. For details on resets, refer to section 4, Exception Handling.

In a power-on reset, the registers and internal statuses of all LSI on-chip modules are initialized. In a manual reset, the register contents of a part of the LSI on-chip modules, such as the bus state controller (BSC), are retained. For details, refer to section 27, List of Registers.

After initialization, the program branches to address H'A0000000 to pass control to the reset processing program defined by the user to be executed.

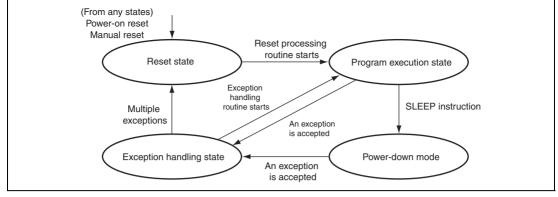

**Exception Handling State:** In the exception handling state, the CPU processing flow is changed temporarily by a general exception or interrupt exception processing. The program counter (PC) and status register (SR) are saved in the save program counter (SPC) and save status register (SSR), respectively. The program branches to an address obtained by adding a vector offset to the vector base register (VBR) and passes control to the exception handling program defined by the user to be executed.

For details on exception handling states, refer to section 4, Exception Handling.

**Program Execution State:** The CPU executes programs sequentially.

**Power-Down State:** The CPU stops operation to reduce power consumption. The power-down state can be entered by executing the SLEEP instruction. For details on the power-down state, refer to section 13, Power-Down Modes.

Figure 2.1 shows a status transition diagram.

**Figure 2.1 Processing State Transitions** 

#### 2.1.2 Processing Modes (User Mode/Privileged Mode)

This LSI supports two processing modes: user mode and privileged mode. These processing modes can be determined by the processing mode bit (MD) in the status register (SR). If the MD bit is cleared to 0, user mode is selected. If the MD bit is set to 1, privileged mode is selected. The CPU automatically enters privileged mode by a transition to the reset state or exception handling state. In privileged mode, any registers and resources in address spaces can be accessed. For details on differences of registers and address spaces which can be accessed by the CPU in each processing mode, refer to section 2.2, Memory Map and section 2.3, Register Descriptions.

Writing 0 to the MD bit in SR puts the CPU in user mode. In user mode, some of the registers, including SR, and some of the address spaces cannot be accessed by the user program and system control instructions cannot be executed. This function effectively protects the system resources from the user program. To change the processing mode from user to privileged mode, a transition to the exception handling state is required.\*<sup>1</sup>\*<sup>2</sup>

- Notes: 1. To call a service routine used in privileged mode from user mode, the LSI supports an unconditional trap instruction (TRAPA).
  - 2. When a transition from user mode to privileged mode occurs, the contents of SR and PC are saved. A program execution in user mode can be resumed by restoring the contents of SR and PC. To return from an exception handling program, the LSI supports an RTE instruction.

## 2.2 Memory Map

The address spaces that can be accessed by the CPU mounted on this LSI differ depending on the processing mode as described above, and the address space handled by the CPU may not match the physical address space. To avoid misunderstandings, the address space which is output by the CPU is referred to as the logical address space while the actual physical address space is referred to as the physical address space. Furthermore, among the physical address space, the space to which this LSI can make external access is referred to as the external address space. These terms are used hereafter in this manual.

#### 2.2.1 Logical Address Space

The address space which is output by the CPU is referred to as the logical address space. The CPU of this LSI supports a 32-bit logical address space and accesses system resources using the 4 Gbytes of logical address space. User programs and data are accessed from the logical address space. From the hardware view, the addresses output from the CPU are used on the L bus (see www.Dafigure 11.1 in section 1, Overview). The logical address space is divided into several areas and managed as shown in figure 2.2.

In privileged mode, 4 Gbytes of space from P0 area to P4 area can be accessed.

In user mode, 2 Gbytes of space in U0 area can be accessed. When the DSP bit in SR is set to 1, 16 Mbytes of space in Uxy area can be also accessed. If areas other than U0 and Uxy are accessed in user mode, an address error occurs.

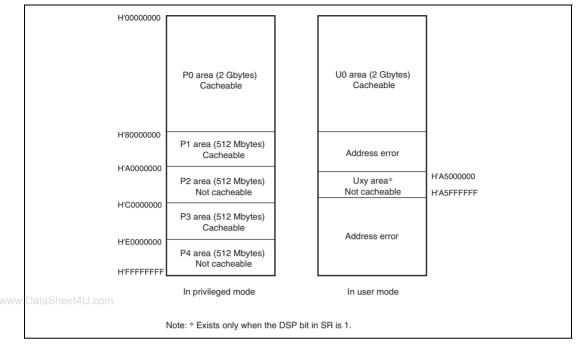

Figure 2.2 Logical Address Space

**P0/U0 Area:** This area is called the P0 area when the CPU is in privileged mode and the U0 area when in user mode. For the P0 and U0 areas, access using the cache is enabled.\*

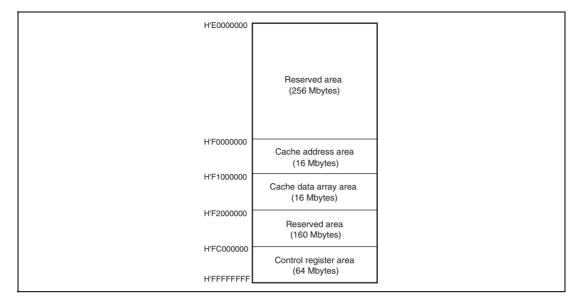

**P1 Area:** The P1 area is defined as a privileged area that is cacheable.\* Normally, this area contains programs that operate at high-speed in privileged mode, such as the kernel of the operating system (OS) and the exception handler.

**P2** Area: The P2 area is defined as a privileged area that is not cacheable. The reset processing program that is initiated when a transition is made to the reset state is written from the start address of the P2 area (H'A0000000). Normally, this area contains programs that are needed to initiate the OS, such as the system initial setting routine. Note that access to several on-chip I/O registers requires the program to be saved in the P2 area.

P3 Area: The P3 area is defined as a privileged area that is cacheable.\*

**P4 Area:** The P4 area is a control space that is not cacheable and can be accessed only in privileged mode. Figure 2.3 shows the P4 area in detail. Several on-chip I/O registers are assigned to this area. For details on I/O registers which are assigned to this area, see section 27, List of Registers.

www.DataShoot4LL.com

Figure 2.3 P4 Area

**Uxy Area:** The Uxy area that can be used when the DSP bit in SR is set to 1 in user mode is mapped to the on-chip memory of this LSI. Accessing this area when the DSP bit is 0 in user mode will result in an address error. This area cannot be accessed through the cache. For details on the Uxy area, see section 6, X/Y Memory and section 7, U Memory. For details on the DSP bit, see section 3, DSP Operating Unit.

Note: \* Whether the cache is used or not is determined according to the CE bit in the cache control register (CCR1).

## 2.2.2 Physical Address Space

The physical address space obtained by address translation of addresses output from the CPU is referred to as the physical address space. From the hardware view, the addresses of the physical address space are used on the I bus. Similar to the logical address space, this LSI supports a 32-bit physical address space. However, as shown in figure 2.4, the upper three bits of the 32 bits are masked and handled as a shadow. Therefore, only 29 bits are actually used to access the physical address space and 0.5 Gbytes of physical memory can be accessed. Replacing the upper three bits of an address in this area with 0s makes the address in the corresponding physical address space.\* For details on the physical address space, see section 9, Bus State Controller (BSC).

Bus masters other than the CPU, e.g. DMAC, are directly connected to the I bus. Therefore, instead of handling the logical address space, they directly handle the physical address space.

Note: \* Since the on-chip I/O registers can be accessed only if the upper three bits of a logical address are set to 111 (corresponding to the P4 area in privileged mode), the upper three bits are output with the same values of 111 on the I bus. www.DataSheet4U.com

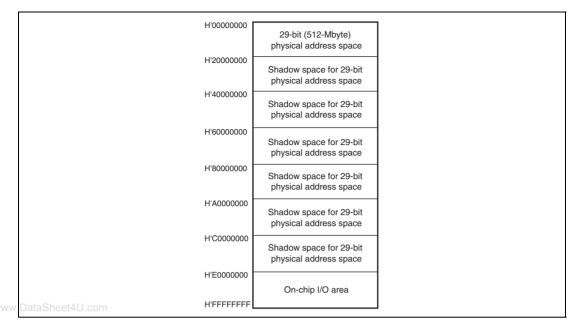

Figure 2.4 Physical Address Space

### 2.2.3 External Address Space

The physical address space is divided into eight areas as shown in figure 2.5. Area 1 is used as the on-chip I/O space, and most of the on-chip registers of this LSI are mapped to this area\*. In this LSI, areas 2 and 5 to 7 are reserved areas. The remaining three areas, areas 0, 3, and 4, are used as the external address space. Each area of the external address space can be connected to different types of memory (for details, see section 9, Bus State Controller (BSC)).

The upper three bits of a logical address are normally masked from the CPU and treated as a shadow. In privileged mode, for example, logical addresses H'00000100 in the P0 area, H'80000100 in the P1 area, H'A0000100 in the P2 area, and H'C0000100 in the P3 area are all mapped to the same external address H'00000100 in area 0. However, since addresses cannot be mapped to the P4 area, the external address space cannot be accessed by an access to the P4 area.

The three areas (areas 0, 3, and 4) to which the external memory can be connected are each a 64-Mbyte external address space. Since this LSI has 24 address pins, a maximum of 16 Mbytes of memory can be mounted for each area. Figure 2.5 shows the mounted space corresponding to area 0.

Note: \* To access an on-chip I/O register mapped to area 1 of the external address space, make an access from the P2 area of the logical address space that is not cacheable.

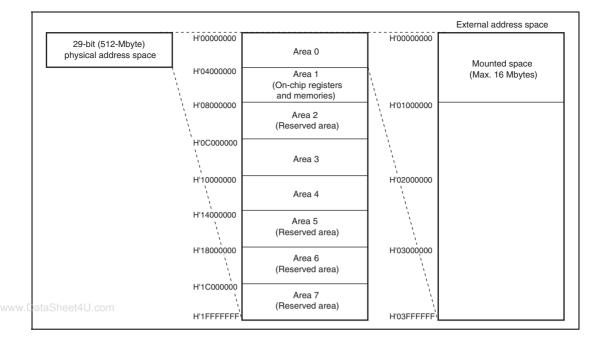

Figure 2.5 External Address Space and Mounted Space (Area 0)

## 2.3 Register Descriptions

The CPU of this LSI provides thirty-three 32-bit registers: 24 general registers, five control registers, three system registers, and one program counter.

**General Registers:** This LSI incorporates 24 general registers: R0\_BANK0 to R7\_BANK0, R0\_BANK1 to R7\_BANK1, and R8 to R15. R0 to R7 are banked. The processing mode and the register bank (RB) bit in the status register (SR) determine which set of banked registers (R0\_BANK0 to R7\_BANK0 or R0\_BANK1 to R7\_BANK1) are accessed as general registers.

**System Registers:** This LSI incorporates the multiply and accumulate registers (MACH/MACL) and procedure register (PR) as system registers. These registers can be accessed regardless of the processing mode.

**Program Counter:** The program counter (PC) stores the value obtained by adding 4 to the current instruction address.

www.DControl Registers: This LSI incorporates the status register (SR), global base register (GBR), save status register (SSR), save program counter (SPC), and vector base register (VBR) as control registers. Only GBR can be accessed in user mode. Control registers other than GBR can be accessed only in privileged mode.

Table 2.1 shows the register values after a reset. Figure 2.6 shows the register configurations in each processing mode.

**Table 2.1 Register Initial Values** 

Register Type	Registers	Initial Values*
General registers	R0_BANK0 to R7_BANK0,	Undefined
	R0_BANK1 to R7_BANK1,	
	R8 to R15	
System registers	MACH, MACL, PR	Undefined
Program counter	PC	H'A0000000
Control registers	SR	MD bit = 1, RB bit = 1, BL bit = 1, I3 to I0 bits = B'1111 (H'F), DSP bit = 0, reserved bits = all 0, other bits = undefined
	GBR, SSR, SPC	Undefined
	VBR	H'00000000

Note: \* Initialized by a power-on reset or manual reset.

Figure 2.6 Register Configuration in Each Processing Mode

### 2.3.1 General Registers

There are twenty-four general registers: R0\_BANK0 to R7\_BANK0, R0\_BANK1 to R7\_BANK1, and R8 to R15. Figure 2.7 shows the general register configuration. R0 to R7 are banked. The processing mode and the register bank (RB) bit in the status register (SR) determine which set of banked registers (R0\_BANK0 to R7\_BANK0 or R0\_BANK1 to R7\_BANK1) are accessed as general registers. R0 to R7 registers in the selected bank are accessed as R0 to R7. R0 to R7 in the non-selected bank is accessed as R0\_BANK to R7\_BANK by the control register load instruction (LDC) and control register store instruction (STC).

In user mode, bank 0 is selected regardless of the RB bit value. Sixteen registers: R0\_BANK0 to R7\_BANK0 and R8 to R15 are accessed as general registers R0 to R15. R0\_BANK1 to R7\_BANK1 registers in bank 1 cannot be accessed.

In privileged mode that is entered by a transition to the exception handling state, the RB bit is set to 1 to select bank 1. In this case, sixteen registers: R0\_BANK1 to R7\_BANK1 in bank 1 and R8 to R15 are accessed as general registers R0 to R15. A bank is switched automatically when an www.Dexception handling state is entered, registers R0 to R7 need not be saved by the exception handling routine. R0\_BANK0 to R7\_BANK0 in bank 0 can be accessed as R0\_BANK to R7\_BANK by the LDC or STC instructions.

In privileged mode, bank 0 can also be used as general registers by clearing the RB bit to 0. In this case, sixteen registers: R0\_BANK0 to R7\_BANK0 in bank 0 and R8 to R15 are accessed as general registers R0 to R15. R0\_BANK1 to R7\_BANK1 in bank 1 can be accessed as R0\_BANK to R7\_BANK by the LDC or STC instructions.

The general registers R0 to R15 are used as equivalent registers for almost all instructions. In some instructions, R0 is implicitly used or only R0 may be used as source or destination registers.

General Registers: Undefined after reset

Notes: 1. R0 functions as an index register in the indexed register-indirect addressing mode and indexed GBR-indirect addressing mode. In some instructions, only R0 can be used as the source or destination register.

R0 to R7 are banked registers.
 In privileged mode, either R0\_BANK0 to R7\_BANK0 or R0\_BANK1 to R7\_BANK1 is selected by the RB bit in SR.

Figure 2.7 General Registers

MAN DataShoot411 com

### 2.3.2 System Registers

The system registers which are the following two registers can be accessed by the LDS or STS instructions. Figure 2.8 shows the system register configuration.

**Multiply and Accumulate Registers:** The multiply and accumulate registers store the results of multiplication and accumulation instructions or multiplication instructions. These registers also store additional values for the multiplication and accumulation instructions. After a reset, these registers are undefined.

The multiply and accumulate registers consist of the multiply and accumulate high register (MACH) which stores the upper 32 bits and multiply and accumulate low register (MACL) which stores lower 32 bits.

**Procedure Register:** The procedure register (PR) stores the return address for a subroutine call using the BSR, BSRF, or JSR instruction. The return address stored in PR is restored to the program counter (PC) by the RTS (return from the subroutine) instruction. After a reset, this register is undefined.

### 2.3.3 Program Counter

The program counter (PC) stores the value obtained by adding 4 to the current instruction address. Figure 2.8 shows the PC configuration. There is no instruction to read PC directly. Before an exception handling state is entered, the PC is saved in the save program counter (SPC). Before a subroutine call is executed, PC is saved in the procedure register (PR). In addition, PC can be used for PC relative addressing mode.

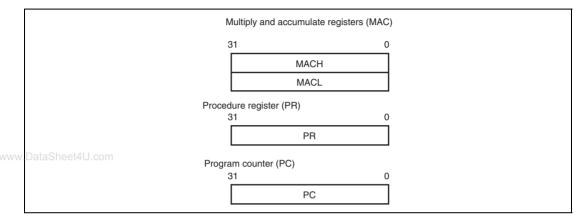

Figure 2.8 System Registers and Program Counter

## 2.3.4 Control Registers

The control registers can be accessed by the LDC or STC instruction in privileged mode. The global base register (GBR) can also be accessed in user mode. The control registers are the following five registers.

**Status Register (SR):** SR stores various information which indicates the system status. SR can be accessed only in privileged mode.

ww.DataSheet4U.com

	Bit	Bit Name	Initial Value	R/W	Description
	31	_	0	R	Reserved
					This bit is always read as 0. The write value should always be 0. When 1 is written to this bit, operation cannot be guaranteed.
	30	MD	1	R/W	Processing Mode
					Indicates the CPU processing mode.
					0: User mode
					1: Privileged mode
					The MD bit is set to 1 after a reset or in an exception handling state.
	29	RB	1	R/W	Register Bank
					The general registers R0 to R7 are banked registers. The RB bit selects a bank used in privileged mode.
DataSheet4U.com			0: Selects bank 0 registers. In this case, R0_BANK0 to R7_BANK0 and R8 to R15 are used as general registers. R0_BANK1 to R7_BANK1 can be accessed by the LDC or STC instruction.		
					1: Selects bank 1 registers. In this case, R0_BANK1 to R7_BANK1 and R8 to R15 are used as general registers. R0_BANK0 to R7_BANK0 can be accessed by the LDC or STC instruction.
					The RB bit is set to 1 after a reset or in an exception handling state.
	28	BL	1	R/W	Block
					0: Enables an interrupt or user break.
					1: Disables an interrupt or user break.
					The BL bit is set to 1 after a reset or in an exception handling state.
	27 to 10	_	All 0	R	Reserved* <sup>2</sup>
					These bits are always read as 0. The write value should always be 0. When 1 is written to these bits, operation cannot be guaranteed.

		Initial		
Bit	Bit Name	Value	R/W	Description
9	М	_	R/W	M Bit*1
8	Q	_	R/W	Q Bit*1
				These bits are used by the DIVOS, DIVOU, and DIV1 instructions. These bits can be changed even in user mode by executing these instructions. These bits are undefined at a reset. These bits do not change in an exception handling state.
7	13	1	R/W	Interrupt Mask Bits
6	12	1	R/W	The 4-bit data indicates the interrupt mask level. These bits
5	l1	1	R/W	do not change even if an interrupt occurs. At a reset, these
4	10	1	R/W	bits are initialized to B'1111. These bits are not affected in an exception handling state.
3, 2	_	All 0	R	Reserved* <sup>2</sup>
always b			These bits are always read as 0. The write value should always be 0. When 1 is written to these bits, operation cannot be guaranteed.	
1	S		R/W	Saturation Mode*1
				Specifies saturation mode for multiply instructions or multiply and accumulate instructions. This bit can be specified by the SETS and CLRS instructions in user mode.
				At a reset, this bit is undefined. This bit is not affected in an exception handling state.
0	T	_	R/W	T Bit*1
				Indicates true or false for compare instructions or carry or borrow occurrence for an operation instruction with carry or borrow. This bit can be specified by the SETT and CLRT instructions in user mode.
				At a reset, this bit is undefined. This bit is not affected in an exception handling state.

Notes: 1. The M, Q, S, and T bits can be set/cleared by the user mode specific instructions.

Other bits can be read or written in privileged mode.

2. When DSP is used, this bit is extended. Refer to section 3.2.3, CPU Register Sets.

**Save Status Register (SSR):** The save status register (SSR) can be accessed only in privileged mode. Before entering the exception handling state, the contents of SR are saved. At a reset, the SSR initial value is undefined.

**Save Program Counter (SPC):** The save program counter (SPC) can be accessed only in privileged mode. Before entering the exception handling state, the contents of PC are saved. At a reset, the SPC initial value is undefined.

**Global Base Register (GBR):** The global base register (GBR) is referenced as a base register in GBR indirect addressing mode. At a reset, the GBR initial value is undefined.

**Vector Base Register (VBR):** The vector base register (VBR) can be accessed only in privileged mode. If a transition from a state other than a reset state to exception handling state occurs, this register is referenced as a base address of the branch destination. For details, refer to section 4, Exception Handling. At a reset, VBR is initialized to H'00000000.

Figure 2.9 shows the control register configuration.

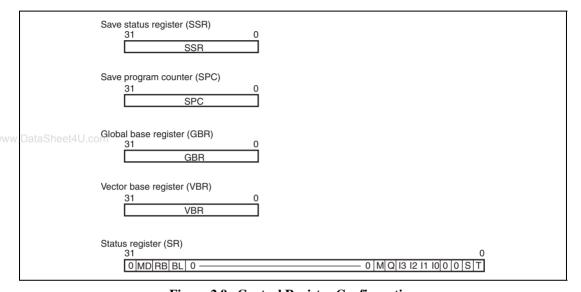

Figure 2.9 Control Register Configuration

#### 2.4 Data Formats

### 2.4.1 Register Data Format

Register operands are always longwords (32 bits). When the memory operand is only a byte (8 bits) or a word (16 bits), it is sign-extended into a longword when loaded into a register.

### 2.4.2 Memory Data Formats

Memory data formats are classified into byte, word, and longword. Memory can be accessed in bytes, words, and longwords. When the memory operand is only a byte (8 bits) or a word (16 bits), it is sign-extended into a longword when loaded into a register.

Word operand must be accessed from word boundary (even address in two bytes: address 2n) and longword operand must be accessed from longword boundary (even address in four bytes: address 4n). Otherwise, an address error will occur and an exception handling state will be entered. Byte operand can be accessed from any address.

When a word or longword operand is accessed, the byte positions on the memory corresponding to the word or longword data on the register is determined according to the specified endian mode (big endian or little endian).

Figure 2.10 shows a byte correspondence in big endian mode. In big endian mode, the MSB byte in the register corresponds to the lowest address in the memory, and the LSB byte in the register corresponds to the highest address. For example, if the contents of the general register R0 is stored at an address indicated by the general register R1 in longwords, the MSB byte in R0 is stored at the address indicated by the R1 and the LSB byte in R0 is stored at the address indicated by the (R1 + 3).

The on-chip device registers assigned to memory are accessed in big endian mode. Note that the available access size (byte, word, or longword) differs in each register.

Note: The CPU instruction codes of this LSI must be stored in words. In big endian mode, the instruction code must be stored from upper byte to lower byte in this order from the word boundary on the memory.

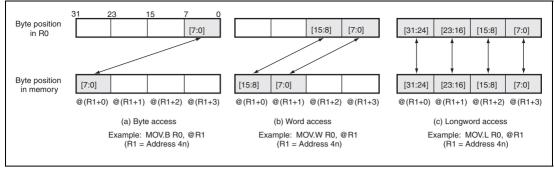

Figure 2.10 Data Format on Memory (Big Endian Mode)

The little endian mode can also be specified as data format. Either big endian or little endian mode should be selected according to the external pin (MD5 pin) at a power-on reset. When the MD5 pin goes low, the processor operates in big endian mode. When the MD5 pin goes high, the processor operates in little endian mode. The endian mode cannot be changed dynamically.

In little endian mode, the MSB byte in the register corresponds to the highest address in the memory, and the LSB byte in the register corresponds to the lowest address (figure 2.11). For example, if the contents of the general register R0 is stored at an address indicated by the general register R1 in longwords, the MSB byte of R0 is stored at the address indicated by the (R1 + 3) and the LSB byte of R0 is stored at the address indicated by R1.

If little endian mode is selected, the on-chip memory of this LSI is accessed in little endian mode. However, the on-chip device registers assigned to memory are accessed in big endian mode. Note that the available access size (byte, word, or longword) differs in each register.

Note: The CPU instruction codes of this LSI must be stored in words. In little endian mode, the instruction code must be stored from lower byte to upper byte in this order from the word boundary on the memory.

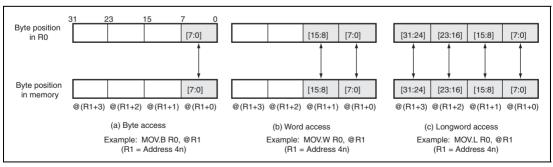

Figure 2.11 Data Format on Memory (Little Endian Mode)

www.DataSheet4U.com

#### 2.5 Features of Instructions

#### 2.5.1 Instruction Execution Method

**Instruction Length:** All instructions have a fixed length of 16 bits and are executed in the sequential pipeline. In the sequential pipeline, almost all instructions can be executed in one cycle. All data are handled in longwords (32 bits). Memory can be accessed in bytes, words, or longwords. In this case, byte or word data is sign-extended and handled as longword data. Immediate data is sign-extended to longword size for arithmetic operations (MOV, ADD, and CMP/EQ instructions) or zero-extended to longword size for logical operations (TST, AND, OR, and XOR instructions).

**Load/Store Architecture:** Basic operations are executed between registers. In operations involving memory, data is first loaded into a register (load/store architecture). However, bit manipulation instructions such as AND are executed directly on memory.

**Delayed Branching:** Unconditional branch instructions are executed as delayed branches. With a delayed branch instruction, the branch is made after execution of the instruction immediately following the delayed branch instruction. This minimizes disruption of the pipeline when a branch is made. An example is shown below. This LSI supports two types of conditional branch instructions: delayed branch instruction and normal branch instruction.

```
BRA TRGET

ADD R1, R0 ; ADD instruction is executed before branching to the TRGET.
```

**T Bit:** The result of a comparison is indicated by the T bit in the status register (SR), and a conditional branch is performed according to whether the result is True or False. Processing speed has been improved by keeping the number of instructions that modify the T bit to a minimum. An example of using the T bit is shown below.

```
ADD #1, R0 ; The T bit cannot be modified by the instruction.

CMP/EQ = \#0, R0 ; The T bit is set to 1 if R0 is 0.
BT = TRGET ; Branch to the TRGET if the T bit is set to 1 (R0 = 0).
```

**Literal Constant:** Byte literal constant is placed inside the instruction code as immediate data. Since the instruction length is fixed to 16 bits, word or longword literal constant is not placed inside the instruction code, but stored as a table in main memory. The table in memory is referenced with a MOV instruction using PC-relative addressing mode with displacement. An example is shown below.

**Absolute Addresses:** The absolute address value should be placed in a table in main memory as well as word or longword literal constant. This value is transferred to a register and the operand access is specified using indexed register indirect addressing mode. The absolute address value is stored in a register during execution of an instruction. This is also applied to the word or longword immediate data.

**16-Bit/32-Bit Displacement:** When data is referenced with a 16- or 32-bit displacement, the displacement value is placed in a table in memory beforehand. As well as the absolute addresses, this value is transferred to a register and the operand access is specified using indexed register indirect addressing mode. The displacement value is stored in a register during execution of an instruction. This is also applied to the word or longword immediate data.

RENESAS

## 2.5.2 Addressing Modes

Table 2.2 shows addressing modes and effective address calculation methods.

**Table 2.2** Addressing Modes and Effective Addresses

	Addressing Mode	Instruction Format	Effective Address Calculation Method	Calculation Formula
	Register	Rn	Effective address is register Rn.	_
	direct		(Operand is register Rn contents.)	
	Register	@Rn	Effective address is register Rn contents.	Rn
	indirect		Rn Rn	
İ	Register	@Rn+	Effective address is register Rn contents. A	Rn
	indirect with post-increment taSheet4U.com		execution: 1 for a byte operand, 2 for a word operand, or 4 for a longword operand.	After instruction execution
				Byte: $Rn + 1 \rightarrow Rn$
				Word: $Rn + 2 \rightarrow Rn$
			1/2/4	Longword: $Rn + 4 \rightarrow Rn$
	Register	@-Rn	Effective address is register Rn contents,	Byte: $Rn - 1 \rightarrow Rn$
	indirect with pre-decrement		decremented by a constant beforehand: 1 for a byte operand, 2 for a word operand, or	Word: $Rn - 2 \rightarrow Rn$
	pre-decrement		4 for a longword operand.	Longword: $Rn - 4 \rightarrow Rn$
			Rn - 1/2/4 Rn - 1/2/4	(Instruction executed with Rn after calculation)

Addressing Mode	Instruction Format	Effective Address Calculation Method	Calculation Formula
Register indirect with displacement	@(disp:4, Rn)	Effective address is register Rn contents with 4-bit displacement disp added. After disp is zero-extended, it is multiplied by 1 (byte), 2 (word), or 4 (longword), according to the operand size.	Byte: Rn + disp  Word: Rn + disp × 2  Longword: Rn + disp × 4
Indexed register indirect  DataSheet4U.com	@(R0, Rn)	Effective address is sum of register Rn and R0 contents.	Rn + R0
GBR indirect with displacement	@(disp:8, GBR)	Effective address is register GBR contents with 8-bit displacement disp added. After disp is zero-extended, it is multiplied by 1 (byte), 2 (word), or 4 (longword), according to the operand size.  GBR  GBR  GBR  GBR  (zero-extended)	Byte: GBR + disp Word: GBR + disp × 2 Longword: GBR + disp × 4

Addressing Mode	Instruction Format	Effective Address Calculation Method	Calculation Formula
Indexed GBR indirect	@(R0, GBR)	Effective address is sum of register GBR and R0 contents.  GBR  GBR + R0	GBR + R0
PC-relative with displacement	@(disp:8, PC)	Effective address is register PC with 8-bit displacement disp added. After disp is zero-extended, it is multiplied by 2 (word) or 4 (longword), according to the operand size. With a longword operand, the lower 2 bits of PC are masked.  PC  PC+disp×2  or PC & H'FFFFFFFFC  (zero-extended)  PC+disp×4	Word: PC + disp × 2 Longword: PC&H'FFFFFFC + disp × 4
PC-relative	disp:8	*: With longword operand  Effective address is register PC with 8-bit displacement disp added after being sign-	PC + disp × 2
		extended and multiplied by 2.  PC  disp (sign-extended)  PC+disp×2	

Addressing Mode	Instruction Format	Effective Address Calculation Method	Calculation Formula
PC-relative	disp:12	Effective address is register PC with 12-bit displacement disp added after being signextended and multiplied by 2.	PC + disp × 2
		disp (sign-extended) PC + disp × 2	
	Rn	Effective address is sum of register PC and Rn contents.	PC + Rn
		PC + Rn PC + Rn	
Immediate DataSheet4U.com	#imm:8	8-bit immediate data imm of TST, AND, OR, or XOR instruction is zero-extended.	_
	#imm:8	8-bit immediate data imm of MOV, ADD, or CMP/EQ instruction is sign-extended.	_
	#imm:8	8-bit immediate data imm of TRAPA instruction is zero-extended and multiplied by 4.	_

Note: For addressing modes with displacement (disp) as shown below, the assembler description in this manual indicates the value before it is scaled (x 1, x 2, or x 4) according to the operand size to clarify the LSI operation. For details on actual assembler description, refer to the description rules in each assembler.

@ (disp:4, Rn) ; Register indirect with displacement

@ (disp:8, GBR) ; GBR indirect with displacement

@ (disp:8, PC) ; PC relative with displacement

disp:8, disp:12 ; PC relative

### 2.5.3 Instruction Formats

Table 2.3 shows the instruction formats and the meaning of the source and destination operands. The meaning of the operands depends on the instruction code. The following symbols are used in the table.

xxxx: Instruction code

mmmm: Source register

nnnn: Destination register

iiii: Immediate data

dddd: Displacement

**Table 2.3** Instruction Formats

www.DaNotes:41.cThe table shows the minimum number of execution states. In practice, the number of instruction execution states will be increased in cases such as the following:

- a. When there is a conflict between an instruction fetch and a data access
- b. When the destination register of a load instruction (memory  $\rightarrow$  register) is also used by the following instruction
- 2. Scaled (x 1, x 2, or x 4) according to the instruction operand size, etc.

Notes: \*1 Minimum number of cycles before the chip enters the sleep state.

\*2 For details, refer to section 4, Exception Handling.

- 1. The table shows the minimum number of cycles required for execution. In practice, the number of execution cycles will be increased in the following conditions.
  - a. If there is a conflict between an instruction fetch and a data access
  - b. If the destination register of a load instruction (memory  $\rightarrow$  register) is also used by the following instruction.
- 2. For addressing modes with displacement (disp) as shown below, the assembler description in this manual indicates the value before it is scaled (x 1, x 2, or x 4) according to the operand size to clarify the LSI operation. For details on assembler description, refer to the description rules in each assembler.
  - @ (disp:4, Rn); Register indirect with displacement
  - @ (disp:8, GBR); GBR indirect with displacement
  - @ (disp:8, PC); PC relative with displacement disp:8, disp:12; PC relative

# 2.6.2 Operation Code Map

Table 2.11 shows the operation code map.

# Section 3 DSP Operating Unit

#### 3.1 DSP Extended Functions

This LSI incorporates a DSP unit and XY memory directly connected to the DSP unit. This LSI supports the DSP extended function instruction sets needed to control the DSP unit and XY memory. The DSP extended function instructions are classified into four groups (figure 3.1).

**Extended System Control Instructions for the CPU:** If the DSP extended function is enabled, the following extended system control instructions can be used for the CPU.

- Repeat loop control instructions and repeat loop control register access instructions are added. Looped programs can be executed efficiently by using the zero-overhead repeat control unit. For details, refer to section 3.3, CPU Extended Instructions.
- Modulo addressing control instructions and control register access instructions are added.
   Function allows access to data with a circular structure. For details, refer to section 3.4, DSP
  - DSP unit register access instructions are added. Some of the DSP unit registers can be used in the same way as the CPU system registers. For details, refer to section 3.4, DSP Data Transfer Instructions.

# Data Transfer Instructions for Data Transfers between DSP Unit and On-Chip XY

**Memory:** Data transfer instructions for data transfers between the DSP unit and on-chip XY memory are called double-data transfer instructions. Instruction codes for these double-transfer instructions are 16-bit codes as well as CPU instruction codes. These data transfer instructions perform data transfers between the DSP unit and on-chip XY memory that is directly connected to the DSP unit. These data transfer instructions can be described in combination with other DSP unit operation instructions. For details, refer to section 3.4, DSP Data Transfer Instructions.

**Data Transfer Instructions for Data Transfers between DSP Unit Registers and All Virtual Address Spaces:** Data transfer instructions for data transfers between DSP unit registers and all virtual address spaces are called single-data transfer instructions. Instruction codes for the double-transfer instructions are 16-bit codes as well as CPU instruction codes. These data transfer instructions performs data transfers between the DSP unit registers and all virtual address spaces. For details, refer to section 3.4, DSP Data Transfer Instructions.

**DSP Unit Operation Instructions:** DSP unit operation instructions are called DSP operation instructions. These instructions are provided to execute digital signal processing operations at high speed using the DSP. Instruction codes for these instructions are 32 bits. The DSP operation instruction fields consist of two fields: field A and field B. In field A, a function for double data transfer instructions can be described. In field B, ALU operation instructions and multiply instructions can be described. The instructions described in fields A and B can be executed in parallel. A maximum of four instructions (ALU operation, number 14 lateory)

transfers) can be executed in parallel. For details, refer to section 3.5, DSP Data Operation Instructions.

- Notes: 1. 32-bit instruction codes are handled as two consecutive 16-bit instruction codes.

  Accordingly, 32-bit instruction codes can be assigned to a word boundary. 32-bit instruction codes must be stored in memory, upper word and lower word, in this order, in word units.
  - 2. In little endian, the upper and lower words must be stored in memory as data to be accessed in word units.

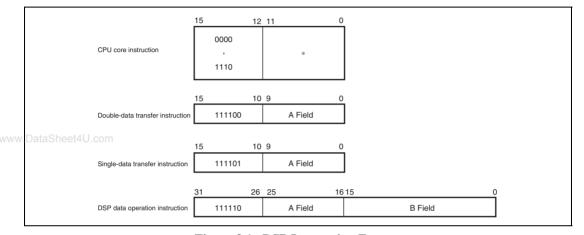

Figure 3.1 DSP Instruction Format

#### 3.2 DSP Mode Resources

#### 3.2.1 Processing Modes

The CPU processing modes can be extended using the mode bit (MD) and DSP bit (DSP) of the status register (SR), as shown below.

			Description				
MD Bit	DSP Bit	Processing Mode	Access of Resources Protected in Privileged Mode or Privileged Instruction Execution	DSP Extended Functions			
0	0	User mode	Prohibited	Invalid			
0	1	User DSP mode	Prohibited	Valid			
1	0	Privileged mode	Allowed	Invalid			
1 ataShee	et4U.com	Privileged DSP mode	Allowed	Valid			

As shown above, the extension of the DSP function by the DSP bit can be specified independently of the control by the MD bit. Note, however, that the DSP bit can be modified only in privileged mode. Before the DSP bit is modified, a transition to privileged mode or privileged DSP mode is necessary.

# 3.2.2 DSP Mode Memory Map

In DSP mode, a part of the P2 area in the virtual address space can be accessed in user DSP mode (H'A5000000 to H'A5FFFFFF of H'A0000000 to H'BFFFFFFF can be accessed) as shown in figure 3.1. When this area is accessed in user DSP mode, this area is referred to as a Uxy area. X/Y memory is then assigned to this Uxy area. Accordingly, X/Y memory can also be accessed in user DSP mode.

Table 3.1 Virtual Address Space

Address Range	Name	Protection	Description
H'A5000000 to H'A5FFFFF	P2/Uxy	Privileged mode or DSP mode	16-Mbyte physical address space, non-cacheable
			Can be accessed in privileged mode and DSP modes (privileged DSP mode and user DSP mode)

# 3.2.3 CPU Register Sets

In DSP mode, the status register (SR) in the CPU unit is extended to add control bits and three control registers: a repeat start register (SR), repeat end register (RE), and modulo register are added as control registers (figure 3.2).

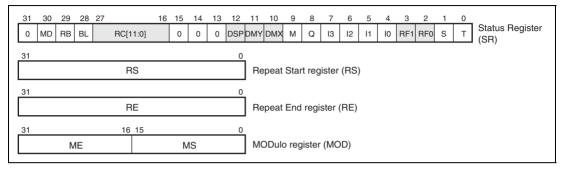

Figure 3.2 CPU Registers in DSP Mode

ww DataSheet4U.com

**Extension of Status Register (SR):** In DSP mode, the following control bits are added to the status register (SR). These added bits are called DSP extended bits. These DSP extended bits are valid only in DSP mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	_	_	_	For details, refer to section 2, CPU.
27 to 16	RC11 to RC0	All 0	R/W	Repeat Counter
				Holds the number of repeat times in order to perform loop control, and can be modified in privileged mode, privileged DSP mode, or user DSP mode. At reset, this bit is initialized to 0. This bit is not affected in the exception handling state.
15 to 13	_	_	—	For details, refer to section 2, CPU.
12	DSP	0	R/W	DSP
taSheet4U	.com			Enables or disables the DSP extended functions. If this bit is set to 1, the DSP extended functions are enabled. This bit can be modified in privileged mode and privileged DSP mode; not in user DSP mode. At reset, this bit is initialized to 0. This bit is not affected in the exception handling state.
11	DMY	0	R/W	Modulo Control
10	DMX	0	R/W	Enable or disable modulo addressing for X/Y memory access. These bits can be modified in privileged mode, privileged DSP mode, or user DSP mode. At reset, these bits are initialized to 0. These bits are not affected in the exception handling state.
9 to 4	_	_	_	For details, refer to section 2, CPU.
3	FR1	0	R/W	Repeat Flag
2	FR0	0	R/W	Used by repeat control instructions. These bits can be modified in privileged mode, privileged DSP mode, or user DSP mode. At reset, these bits are initialized to 0. These bits are not affected in the exception handling state.
1 to 0	_	_		For details, refer to section 2, CPU.

Note: When data is written to the SR register, 0 should be written to reserved bits (bits 31, 15 to 13).

**Repeat Start Register (RS):** RS holds the start address of the repeat loop that is controlled by the zero overhead repeat control function. This register can be accessed in DSP mode. At reset, the initial value of this register is undefined. This register is not affected in the exception handling state.

Repeat End Register (RE): RE holds the address for detecting the execution of the end instruction of repeat loop that is controlled by the zero overhead repeat control function. This register can be accessed in DSP mode. At reset, this register is initialized to 0. This register is not affected in the exception handling state.

**Modulo Register (MOD):** MOD stores the modulo end address and modulo start address for modulo addressing in upper and lower 16 bits. The upper and lower 16 bits of the MOD register are referred to as the ME register and MS register, respectively. This register can be accessed in DSP mode. At reset, the initial value of this register is undefined. This register is not affected in the exception handling state.

The above registers can be accessed by the control register load instruction (LDC) and store instruction (STC). Note that the LDC and STC instructions for the RS, RE, and MOD registers can be used only in privileged DSP mode and user DSP mode. The LDC and STC instruction for the SR register can be executed only when the MD bit is set to 1 or in user DSP mode. Note, however, that the LDC and STC instructions can modify only the RC11 to RC0, RF1 to RF0, DMX, and DMY bits in the SR, as described below.

- In user mode, if the LCD and STC instructions are used for the SR, an illegal instruction exception occurs.
- In privileged and privileged DSP modes, all SR bits can be modified.
- In user DSP mode, the SR can be read by the STC instruction.
   In user DSP mode, the LDC instruction can be issued to the SR but only the DSP extension bits can be modified.

**Table 3.2** Operation of SR Bits in Each Processing Mode

	Privileged Mode	User Mode	Privileged DSP Mode	User DSP Mode	Access to DSP-Related Bit with

## Legend

S: STC instruction L: LDC instruction

OK: STC/LDC operation is enabled.

Invalid instruction: Exception occurs when an illegal instruction is executed.

NG: Previous value is retained. No change.

x: Undefined

Before entering the exception handling state, all bits including the DSP extended bits of the SR registers are saved in the SSR. Before returning from the exception handling, all bits including the DSP extended bits of the SR must be restored. If the repeat control must be recovered before entering the exception handling state, the RS and RE registers must be recovered to the value that existed before exception handling. In addition, if it is necessary to recover modulo control before entering the exception handling state, the MOD register must be recovered to the value that existed before exception handling.

#### 3.2.4 DSP Registers

The DSP unit incorporates eight data registers (A0, A1, X0, X1, Y0, Y1, M0, and M1) and a status register (DSR). Figure 3.3 shows the DSP register configuration. These are 32-bit width registers with the exception of registers A0 and A1. Registers A0 and A1 include 8 guard bits (fields A0G and A1G), giving them a total width of 40 bits. The DSR register stores the DSP data operation result (zero, negative, others). The DSP register has a DC bit whose function is similar to the T bit of the CPU register. For details on DSR bits, refer to section 3.5, DSP Data Operation Instructions.

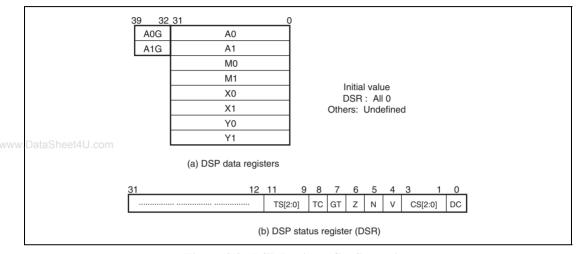

Figure 3.3 DSP Register Configuration

#### 3.3 CPU Extended Instructions

#### 3.3.1 DSP Repeat Control

In DSP mode, a specific function, zero overhead repeat control function, is provided to execute repeat loops efficiently. By using this function, loop programs can be executed without overhead caused by the compare and branch instructions. When describing the repeat loop, the repeat control instructions in table 3.4, the repeat control macro instructions in table 3.5, and the DSP mode extended system control instructions in table 3.6 are used.

**Examples of Repeat Loop Programs:** Examples of repeat loop programs are shown below.

• Example 1: Repeat loop consisting of 4 or more instructions

```
LDRS RptStart ; Sets repeat start instruction address
                            to the RS register
                                ; Sets (repeat detection instruction
          LDRE RptStart +4
                            address + 4) to the RE register
          SETRC #4
                          ; Sets the number of repetitions (4) to
                            the RC[11:0] bits of the SR register
          Instr0
                          ; At least one instruction is required
                            from SETRC instruction to [Repeat start
                            instructionl
RptStart: instr1
                         ; [Repeat start instruction]
                         ;
          . . . . . .
          . . . . . .
RptDtct: instr(N-3)
                               ; [Repeat start instruction]
                                  Three instruction prior to the repeat
                                end instruction is regarded as repeat
                                  detection instruction
RptEnd2: instr(N-2)
                         ;
RptEnd1: instr(N-1)
RptEnd:
          instrN
                         ; [Repeat end instruction]
```

In the above program example, instructions from the RptStart address (instr1 instruction) to the RptEnd address (instrN instruction) are repeated four times. These repeated instructions in the program are called repeat loop. The start and end instructions of the repeat loop are called the repeat start instruction and repeat end instruction, respectively. The CPU sequentially executes instructions and starts repeat loop control if the CPU detects the completion of a specific instruction. This specific instruction is called the repeat detection instruction. In a repeat loop consisting of four or more instructions, an instruction three instructions prior to the repeat end instruction is regarded as the repeat detection instruction. In a repeat loop consisting of four or

more instructions, the same instruction is regarded as the RptStart instruction and RptDtct instruction.

To control the repeat loop, the DSP extended control registers, such as the RE register and RS register and the RC[11:0] and RF[1:0] bits of the SR register, are used. These registers can be specified by the LDRE, LDRS, and SETRC instructions.

- Repeat end register (RE)
  - The RE register is specified by the LDRE instruction. The RE register specifies (repeat detection instruction address +4). In a repeat loop consisting of 4 or more instructions, an instruction three instructions prior to the repeat end instruction is regarded as the repeat detection instruction. A repeat loop consisting of three or less instructions is described later.
- Repeat start register (RS)

The RE register is specified by the LDRS instruction. In a repeat loop consisting of 4 or more instructions, the RS register specifies the repeat start instruction address. In a repeat loop consisting of three or less instructions, a specific address is specified in the RS. This is described later.

- Repeat counter (RC[11:0] bits of the SR)

  The repeat counter is specifies the number of repetitions by the SETRC instruction. During repeat loop execution, the RC holds the remaining number of repetitions.
- Repeat flags (RF[1:0] bits of the SR)
   The repeat flags are automatically specified according to the RS and RE register values during SETRC instruction execution. The repeat flags store information on the number of instructions included in the repeat loop. Normally, the user cannot modify the repeat flag values.

The CPU always executes instructions by comparing the RE register to program counter values. Because the PC stores (the current instruction address +4), if the RE matches the PC during repeat instruction detection execution, a repeat detection instruction can be detected. If a repeat detection instruction is executed without branching and if RC[11:0] > 0, then repeat control is performed. If  $RC[11:0] \ge 2$  when the repeat end instruction is completed, the RC[11:0] is decremented by 1 and then control is passed to the address specified by the RS register.

Examples 2 to 4 show program examples of the repeat loop consisting of three instructions, two instructions, and one instruction, respectively. In these examples, an instruction immediately prior to the repeat start instruction is regarded as a repeat detection instruction. The RS register specifies the specific value that indicates the number of repeat instructions.

# • Example 2: Repeat loop consisting of three instructions

LDRS RptStart +4 ; Sets (repeat detection instruction address + 4) to the RS register

LDRE RptStart +4 ; Sets (repeat detection instruction address + 4) to the RE register

SETRC #4 ; Sets the number of repetitions (4) to

the RC[11:0] bits of the SR register; If RE-RS==0 during SETRC instruction

execution, the repeat loop is regarded as three-instruction repeat.

> An instruction prior to the Repeat start instruction is regarded as a repeat detection instruction.

At least one instruction is required from LDRC instruction to [Repeat start

instruction]

; [Repeat start instruction]

Instr2 ;

RptEnd: instr3 ; [Repeat end instruction]

#### • Example 3: Repeat loop consisting of two instructions

LDRS RptStart +6 ; Sets (repeat detection instruction address + 6) to the RS register

LDRE RptStart +4 ; Sets (repeat detection instruction address + 4) to the RE register

address + 4) to the KE register

SETRC #4 ; Sets the number of repetitions (4) to the RC[11:0] bits of the SR register

; If RE-RS==-2 during SETRC instruction

execution, the repeat loop is regarded

as two-instruction repeat.

RptDtct: instr0 ; [Repeat start instruction]

An instruction prior to the Repeat start instruction is regarded as a

repeat detection instruction.

At least one instruction is required from LDRC instruction to [Repeat start

instructionl

RptEnd: instr2 ; [Repeat end instruction]

# • Example 4: Repeat loop consisting of one instruction

```
LDRS RptStart +8
                                      ; Sets (repeat detection instruction
                                 address + 8) to the RS register
                                      : Sets (repeat detection instruction
                LDRE RptStart +4
                                 address + 4) to the RE register
                SETRC #4
                               ; Sets the number of repetitions (4) to
                                 the RC[11:0] bits of the SR register
                               ; If RE-RS==-4 during SETRC instruction
                            execution, the repeat loop is regarded
                                 as one-instruction repeat.
                               ; [Repeat start instruction]
      RptDtct: instr0
                                 An instruction prior to the Repeat
                               start instruction is regarded as a
                               repeat detection instruction.
                                 At least one instruction is required
                                 from LDRC instruction to [Repeat start
                                 instructionl
www.DataRptStart:
      RptEnd:
               instr1
                               ; [Repeat start instruction] ==
                                [Repeat end instruction]
```

In repeat loops consisting of three instructions, two instructions and one instruction, specific addresses are specified in the RS register. RE-RS is calculated during SETRC instruction execution, and the number of instructions included in the repeat loop is determined according to the result. A value of 0, -2, and -4 in the result correspond to 3 instructions, two instructions, and

If repeat instruction execution is completed without branching and if RC[11:0] > 0, an instruction following the repeat detection instruction is regarded as a repeat start instruction and instruction execution is repeated for the number of times corresponding to the recognized number of instructions. If  $RC[11:0] \ge 2$  when the repeat end instruction is completed, the RC[11:0] is decremented by 1 and then control is passed to the address specified by the RS register. If RC[11:0] ==1 (or 0) when the repeat end instruction is completed, the RC[11:0] is cleared to 0 and then the control is passed to the next instruction following the repeat end instruction.

Note: If RE – RS is a positive value, the CPU regards the repeat loop as a four-instruction repeat loop. (In a repeat loop consisting of four or more instructions, RE – RS is always a positive value. For details, refer to example 1 above.) If RE – RS is positive, or a value other than 0, –2, and –4, correct operation cannot be guaranteed.

one instruction, respectively.

The rule is shown in table 3.3.

Table 3.3 RS and RE Setting Rule

#### **Number of Instructions in Repeat Loop**

Regist	er 1	2	3	≥4
RS	RptStart0 + 8	RptStart0 + 6	RptStart0 + 4	RptStart
RE	RptStart0 + 4	RptStart0 + 4	RptStart0 + 4	RptEnd3 + 4

Note: The terms used above in table 3.3, are defined as follows.

RptStart: Address of the repeat start instruction

RptStart0: Address of the instruction one instruction prior to the repeat start instruction RptEnd3: Address of the instruction three instructions prior to the repeat end instruction

**Repeat Control Instructions and Repeat Control Macros:** To describe a repeat loop, the RS and RE registers must be specified appropriately by the LDRS and LDRE instructions and then the number of repetitions must be specified by the SERTC instruction. An 8-bit immediate data or a general register can be used as an operand of the SETRC instruction. To specify the RC as a value greater than 256, use SETRC Rm type instructions.

**Table 3.4** Repeat Control Instructions

Instruction	Operation	Number of Execution States
LDRS @(disp,PC)	Calculates (disp x 2 + PC) and stores the result to the RS register	1
LDRE @(disp,PC)	Calculates (disp x 2 + PC) and stores the result to the RE register	1
SETRC #imm	Sets 8-bit immediate data imm to the RC[11:0] bits of the SR register and sets the information related to the number of repetitions to the RF[1:0] bits of the SR.	1
	RC[11:0] can be specified as 0 to 255.	
SETRC Rm	Sets the[11:0] bits of the Rm register to the RC[11:0] bits of the SR register and sets the information related to the number of repetitions to the RF[1:0] bits of the SR.	1
	RC[11:0] can be specified as 0 to 4095.	

The RS and RE registers must be specified appropriately according to the rules shown in table 3.3. The SH assembler supports control macros (REPEAT) as shown in table 3.5 to solve problems.

**Table 3.5** Repeat Control Macros

Instruction	Operation	Number of Execution States
REPEAT RptStart, RptEnd, #imm	Specifies RptStart as repeat start instruction, RptEnd as repeat end instruction, and 8-bit immediate data #imm as number of repetitions. This macro is extended to three instructions: LDRS, LDRE, and SETRC which are converted correctly.	3
REPEAT RptStart, RptEnd, Rm	Specifies RptStart as repeat start instruction, RptEnd as repeat end instruction, and the [11:0] bits of Rm as number of repetitions. This macro is extended to three instructions: LDRS, LDRE, and SETRC which are converted correctly.	3

Using the repeat macros shown in table 3.5, examples 1 to 4 shown above can be simplified to examples 5 to 8 as shown below.

• Example 5: Repeat loop consisting of 4 or more instructions (extended to the instruction stream shown in example 1, above)

```
REPEAT RptStart, RptEnd, #4

Instr0 ;

RptStart: instr1 ; [Repeat start instruction]

... ;

instr (N-3) ; [Repeat detection instruction]

instr (N-2) ;

instr (N-1) ;

RptEnd: instrN ; [Repeat end instruction]
```

• Example 6: Repeat loop consisting of three instructions (extended to the instruction stream shown in example 2, above)

```
REPEAT RptStart, RptEnd, #4

instr0 ; [Repeat detection instruction]

RptStart: instr1 ; [Repeat start instruction]

Instr2 ;

RptEnd: instr3 ; [Repeat end instruction]
```

• Example 7: Repeat loop consisting of two instructions (extended to the instruction stream shown in example 3, above)

```
REPEAT RptStart, RptEnd, #4
instr0; [Repeat detection instruction]
RptStart: instr1; [Repeat start instruction]
RptEnd: instr2; [Repeat end instruction]
```

• Example 8: Repeat loop consisting of one instruction instructions (extended to the instruction stream shown in example 3, above)

In the DSP mode, the system control instructions (LDC and STC) that handle the RS and RE registers are extended. The RC[11:0] bits and RF[1:0] bits of the SR can be controlled by the LDC and STC instructions for the SR register. These instructions should be used if an exception is enabled during repeat loop execution. The repeat loop can be resumed correctly by storing the RS and RE register values and RC[11:0] bits and RF[1:0] bits of the SR register before exception handling and by restoring the stored values after exception handling. However, note that there are some restrictions on exception acceptance during repeat loop execution. For details refer to section 3.3.1 (3), Restrictions on Repeat Loop Control and section 4, Exception Handling.

**Table 3.6 DSP Mode Extended System Control Instructions** 

Instruction	Operation	<b>Number of Execution States</b>
STC RS, Rn	RS→Rn	1
STC RE, Rn	RE→Rn	1
STC.L RS, @-Rn	Rn-4→Rn, RS→(Rn)	1
STC.L RE, @-Rn	Rn-4→Rn, RE→(Rn)	1
LDC.L @Rn+, RS	(Rn)→RS, Rn+4→Rn	4
LDC.L @Rn+, RE	(Rn)→RE, Rn+4→Rn	4
LDC Rn,RS	Rn→RS	4
LDC Rn, RE	Rn→RE	4
		<u> </u>

#### **Restrictions on Repeat Loop Control**

- 1. Repeat control instruction assignment
  - The SETRC instruction must be executed after executing the LDRS and LDRE instructions. In addition, note that at least one instruction is required between the SETRC instruction and a repeat start instruction.
- 2. Illegal instruction one or more instructions following the repeat detection instruction
  If one of the following instructions is executed between an instruction following a repeat
  detection instruction to a repeat end instruction, an illegal instruction exception occurs.
  - Branch instructions
    - BRA, BSR, BT, BF, BT/S, BF/S, BSRF, RTS, BRAF, RTE, JSR, JMP, TRAPA
  - Repeat control instructions
    - SETRC, LDRS, LDRE
  - Load instructions for SR, RS, and RE registers
     LDC Rn,SR, LDC @Rn+,SR, LDC Rn,RE, LDC @Rn+,RE, LDC Rn,RS, LDC @Rn+,RS
- Note: This restriction applies to all instructions for a repeat loop consisting of one to three instructions and to three instructions including a repeat end instruction.
  - 3. Instructions prohibited during repeat loop (In a repeat loop consisting of four or more instructions)
    - The following instructions must not be placed between the repeat start instruction and repeat detection instruction in a repeat loop consisting of four or more instructions. Otherwise, the correct operation cannot be guaranteed.
    - Repeat control instructions
       SETRC, LDRS, LDRE
    - Load instructions for SR, RS, and RE registers
       LDC Rn,SR, LDC @Rn+,SR, LDC Rn,RE, LDC @Rn+,RE, LDC Rn,RS, LDC @Rn+,RS

Note: Multiple repeat loops cannot be guaranteed. Describe the inner loop by repeat control instructions, and the external loop by other instructions such as DT or BF/S.

- 4. Branching to an instruction following the repeat detection instruction and restriction on an exception acceptance
  - Execution of a repeat detection instruction must be completed without any branch so that the CPU can recognize the repeat loop. Therefore, when the execution branches to an instruction following the repeat detection instruction, the control will not be passed to a repeat start instruction after executing a repeat end instruction because the repeat loop is not recognized by the CPU. In this case, the RC[11:0] bits of the SR register will not be changed.
  - If a conditional branch instruction is used in the repeat loop, an instruction before a repeat detection instruction must be specified as a branch destination.

www.DataSheet4U.com

— If a subroutine call is used in the repeat loop, a delayed slot instruction of the subroutine call instruction must be placed before a repeat detection instruction.

Here, a branch includes a return from an exception handling routine. If an exception whose return address is placed in an instruction following the repeat detection instruction occurs, the repeat control cannot be returned correctly. Accordingly, an exception acceptance is restricted from the repeat detection instruction to the repeat end instruction. Exceptions such as interrupts that can be retained by the CPU are retained. For exceptions that cannot be retained by the CPU, a transition to an exception occurs but a program cannot be returned to the previous execution state correctly. For details, refer to section 4, Exception Handling.

- Notes: 1. If a TRAPA instruction is used as a repeat detection instruction, an instruction following the repeat detection instruction is regarded as a return address. In this case, a control cannot be returned to the repeat control correctly. In a TRAPA instruction, an address of an instruction following the repeat detection address is regarded as return address. Accordingly, to return to the repeat control correctly, place a return address prior to the repeat detection instruction.
- www.DataSheet42. If a SLEEP instruction is placed following a repeat detection instruction, a transition to the power-down state or an exception acceptance such as interrupts can be performed correctly. In this case, however, the repeat control cannot be returned correctly. To return to the repeat control correctly, the SLEEP instruction must be placed prior to the repeat detection instruction.
  - 5. Branch from a repeat detection instruction

If a repeat detection instruction is a delayed slot instruction of a delayed branch instruction or a branch instruction, a repeat loop can be acknowledged when a branch does not occur in a branch instruction. If a branch occurs in a branch instruction, a repeat control is not performed and a branch destination instruction is executed.

6. Program counter during repeat control

If  $RC[11:0] \ge 2$ , the program counter (PC) value is not correct for instructions two instructions following a repeat detection instruction. In a repeat loop consisting of one to three instructions, the PC indicates the correct value (instruction address + 4) for an instruction (repeat start instruction) following a repeat detect ion instruction but the PC continues to indicate the same address (repeat start instruction address) from the subsequent instruction to a repeat end instruction. In a repeat loop consisting of four or more instructions, the PC indicates the correct value (instruction address + 4) for an instruction following a repeat detect ion instruction, but PC indicates the RS and (RS +2) for instructions two and three instructions following the repeat detection instruction. The correct operation cannot be guaranteed for the incorrect PC values.

Accordingly, PC relative addressing instructions placed two or more instructions following the repeat detection instruction cannot be executed correctly and the correct results cannot be obtained.

# — PC relative addressing instructions

MOV.A @(disp, PC), Rn

MOV.W @(disp, PC), Rn

MOV.L @(disp, PC), Rn

(Including the case when the MOV #imm,Rn is extended to MOV.W @(disp, PC), Rn or MOV.L @(disp, PC), Rn)

Table 3.7 PC Value during Repeat Control (When  $RC[11:0] \ge 2$ )

### **Number of Instructions in Repeat Loop**

	1	2	3	≥4
RptDtct	RptDtct + 4	RptDtct + 4	RptDtct + 4	RptDtct +4
RptDtct1	RptDtct1 + 4	RptDtct1+ 4	RptDtct1 + 4	RptDtct1 + 4
RptDtct2	_	RptDtct1+ 4	RptDtct1 + 4	RS
RptDtct3	_	_	RptDtct1 + 4	RS + 2

Note: In table 3.7, the following symbols are used.

RptDtct: An address of the repeat detection instruction

RptDtct1: An address of the instruction one instruction following the repeat start

instruction (In a repeat loop consisting of one to three instructions, RptStart is

a repeat start instruction)

RptDtct2: An address of the instruction two instruction following the repeat start

instruction

RptDtct3: An address of the instruction three instruction following the repeat start

instruction

# 7. Repeat counter and repeat control

The CPU always executes a program with comparing the repeat end register (RE) and the program counter (PC). If the PC matches the RE while the RC[11:0] bits of the SR register are other than 0, the repeat control function is initiated.

- If RC ≥ 2, a control is passed to a repeat start instruction after a repeat end instruction has been executed. The RC is decremented by 1 at the completion of the repeat end instruction. In this case, restrictions (a) to (f) are also applied.
- If RC == 1, the RC is decremented to 0 at the completion of the repeat end instruction and a control is passed to the subsequent instruction. In this case, restrictions (a) to (f) are also applied.
- If RC == 0, the repeat control function is not initiated even if a repeat detection instruction is executed. The repeat loop is executed once as normal instructions and a control is not be passed to a repeat start instruction even if a repeat end instruction is executed.

www.DataSheet4U.com

# 3.3.2 Extended Repeat Control Instructions

In the repeat control function described in section 3.3.1, Repeat Control Instructions, there are some restrictions. To reduce these restrictions, this LSI supports the extended repeat instructions to extend the repeat control function that are shown in table 3.8. These extended repeat control instructions were not supported in the conventional SH-DSP. To keep compatibility with the conventional SH-DSP, use the conventional repeat control instructions called compatible repeat control instructions.

**Program Examples Using the Extended Repeat Control Instructions:** Examples of repeat loop programs using the extended repeat control instructions are shown below.

• Example 1: Repeat loop consisting of 4 or more instructions

```
LDRS RptStart
                               ; Sets repeat start instruction address
                                  to the RS register
              LDRE RotEnd
                               ; Sets repeat end instruction address
                              to the RE register
www.DataSheet4U.cdrDRC #4
                               ; Sets the number of repetitions (4) to
                                  the RC[11:0] bits of the SR register
                                ; At least one instruction is required
              instr0
                                 from LDRC instruction to [Repeat start
                                  instructionl
                               ; [Repeat start instruction]
       RptStart: instr1
                               ;
              . . . . . .
              . . . . . .
              instr(N-3)

[Repeat end instruction]

www.DataSheet4U.com

In extended repeat control instructions, a repeat start instruction address and a repeat end instruction address are stored in the RS register and RE register, respectively, regardless of the number of repeat instructions. In addition, the extended repeat control can be performed by using the LDRC instruction instead of the SETRC instruction. During the extended repeat control, a repeat loop can be recognized by executing a repeat end instruction. Therefore, there is no restriction on branches or exceptions.

**Extended Repeat Control Instructions:** To describe the extended repeat loop, the repeat start and end addresses must be specified to the RS and RE registers by the LDRS and LDRE instructions, respectively. For the LDRS and LDRE instructions of the extended repeat control instructions, the LDRS and LDRE instructions of the compatible repeat control instructions are used. The number of repetitions are specified by the LDRC instruction. An 8-bit immediate data or the general register values can be used as an operand of the LDRC instruction. If 256 or greater value is specified to the RC, use the LDRC Rm type instructions.

**Table 3.8 Extended Repeat Control Instructions** 

Instruction	Operation	Number of Execution States
LDRS @(disp,PC)	Calculates (disp $\times$ 2 + PC) and stores the result to the RS register	1
LDRE @(disp,PC)	Calculates (disp $\times$ 2 + PC) and stores the result to the RE register	1
LDRC #imm	Sets 8-bit immediate data imm to the RC[11:0] bits of the SR register and sets the information related to the number of repetitions to the RF[1:0] bits of the SR. RC[11:0] can be specified as 0 to 255.	1
	During extended repeat control, bit 0 of the RE register is set to 1.	
LDRC Rm	Sets the[11:0] bits of the Rm register to the RC[11:0] bits of the SR register and sets the information related to the number of repetitions to the RF[1:0] bits of the SR. RC[11:0] can be specified as 0 to 4095.	1
.DataSHEERO.COIII	During extended repeat control, bit 0 of the RE register is set to 1.	

By executing the LDRC instruction, the CPU performs the extended repeat control function. To indicate that the CPU is being in extended repeat control, bit 0 of the RE register is set to 1 by executing the LDRC instruction. To change the RE register value by a process such as an exception handling, bit 0 of the RE register must be saved and restored correctly. By saving and restoring the RC[11:0] bits, DSP bit, and RF[1:0] bits of the SR register, RE register, and RS register correctly, a control is returned to the extended repeat function correctly after processing such as exception handling.

# **Restrictions on Extended Repeat Loop Control:**

1. Extended repeat control instruction assignment

The LDRC instruction must be executed after executing the LDRS and LDRE instructions. In addition, note that at least one instruction is required between the LDRC instruction and a repeat start instruction.

- 2. Illegal instruction one or more instructions following the repeat end instruction
  If one of the following instructions is executed as a repeat end instruction, an illegal instruction
  exception occurs.
  - Delayed branch instructions
     BRA, BSR, BT/S, BF/S, BSRF, RTS, BRAF, RTE, JSR, JMP
  - Repeat control instructions
     SETRC, LDRS, LDRE, LDRC
  - Load instructions for SR, RS, and RE registersLCD Rn,SR, LDC @Rn+,SR, LDC Rn,RE, LDC @Rn+,RE, LDC Rn,RS, LDC @Rn+,RS

Note: A branch instruction without delay (BT, BF, TRAPA) can be placed as a repeat end instruction. A delay stop of a delayed branch instruction can also be placed as a repeat end instruction. In this case, the RC[11:0] value is decremented by 1 regardless of branch occurrence. If no branch occurs, a control returns to a repeat start instruction. If a branch occurs, a control is passed to a branch destination.

3. Repeat counter and repeat control

The CPU always execute a program with comparing the repeat end register (RE) and the (PC - 4) (current instruction address). If the (PC - 4) [31:1] matches the RE [31:1] while bit 0 of RE register is set to 1, the extended repeat control function is initiated.

- If  $RC \ge 2$ , a control is passed to a repeat start instruction after a repeat end instruction has been executed. The RC is decremented by 1 at the completion of the repeat end instruction.
- If RC == 1, the RC is decremented to 0 at the completion of the repeat end instruction and a control is passed to the subsequent instruction.
- If RC == 0, the repeat control function is not initiated even if a repeat detection instruction is executed. The repeat loop is executed once as normal instructions and a control is not be passed to a repeat start instruction even if a repeat end instruction is executed.

#### 3.4 DSP Data Transfer Instructions

In DSP mode, data transfer instructions are added for the DSP unit registers. The newly added instructions are classified into the following three groups.

#### 1. Double data transfer instructions

The DSP unit is connected to the X memory and Y memory via the specific buses called X bus and Y bus. By using the data transfer instructions using the X and Y buses, two data items can be transferred between the DSP unit and X/Y memories simultaneously. These instructions are called double data transfer instructions. These double data transfer instructions can be described in combination with the DSP operation instructions to execute data transfer and data operation in parallel.

# 2. Single data transfer instructions

The DSP unit is also connected to the L bus that is used by the CPU. The DSP registers other than the DSR can access any virtual addresses generated by the CPU. In this case, the single data transfer instructions are used. The single data transfer instructions cannot be used in www.Data combination with the DSP operation instructions and can access only one data item at a time.

#### 3. System control instructions

Some of the DSP unit registers are handled as the CPU system registers. To control these system registers, the system control registers are supported. The DSP registers are connected to the CPU general registers via the data transfer bus (C bus).

In any DSP data transfer instructions, an address to be accessed is generated and output by the CPU. For DSP data transfer instructions, some of the CPU general registers are used for address generation and specific addressing modes are used.

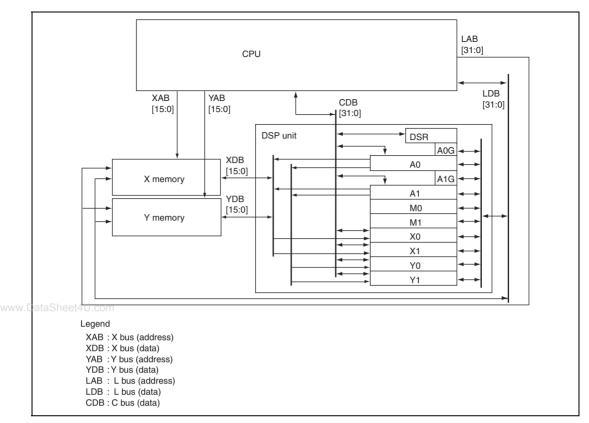

Figure 3.4 DSP Registers and Bus Connections

# Double data transfer instructions (MOVX.W, MOVY.W, MOVX.L, and MOVY.L):

Instruction formats of double data transfer instructions are shown in table 3.12. With double data transfer group instructions, X memory and Y memory can be accessed in parallel.

In this case, the specific buses called X bus and Y bus are used to access X memory and Y memory, respectively. To fetch the CPU instructions, the L bus is used. Accordingly, no conflict occurs among X, Y, and L buses.

Load instructions for X memory specify the X0 or X1 register as the destination operand. Load instructions for Y memory specify the Y0 or Y1 register as the destination operand. Store registers for X or Y memory specify the A0 or A1 register as the source operand. The double data transfer instructions use only word data (16 bits). When a word data transfer instruction is executed, the upper word of register operand is used. To load word data, data is loaded to the upper word of the destination register and the lower word of the destination register is automatically cleared to 0.

Double data transfer instructions can be described in parallel to the DSP operation instructions. Even if a conditional operation instruction is specified in parallel to a double data transfer www.DataSheet4U.com

instruction, the specified condition does not affect the data transfer operations. For details, refer to section 3.5, DSP Data Operation Instructions.

Double data transfer instructions can access only the X memory or Y memory and cannot access other memory space. The X bus and Y bus are 16 bits and support 64-kbyte address spaces corresponding to address areas H'A5000000 to H'A500FFFF and H'A5010000 to H'A501FFFF, respectively. Because these areas are included in the P2/Uxy area, they are not affected by the cache and address translation unit.

Single data transfer instructions: The instruction formats of single data transfer instructions are shown in table 3.13. The single data transfer instructions access any memory location. All DSP registers\* other than the DSR can be specified as source and destination operands. Guard bit registers A0G and A1G can also be specified as two independent registers. Because the single data transfer instructions use the L bus (LAB and LDB), these instructions can access any virtual space handled by the CPU. If these instructions access the cacheable area while the cache is enabled, the area accessed by these instructions are cached. The X memory and Y memory are mapped to the virtual address space and can also be accessed by the single data transfer www.Dinstructions: In this case, bus conflict may occur between data transfer and instruction fetch because the CPU also uses the L bus for instruction fetches.

The single data transfer instructions can handle both word and longword data. In word data transfer, only the upper word of the operand register is valid. In word data load, word data is loaded into the upper word of the destination registers and the lower word of the destination is automatically cleared to 0. If the guard bits are supported, the sign bit is extended before storage. In longword data load, longword data is loaded into the upper and lower word of the destination register. If the guard bits are supported, the sign bit is extended before storage. When the guard register is stored, the sign bit is extended to the upper 24 bits of the LDB and are loaded onto the LDB bus.

Notes: \* Because the DSR register is defined as the system register, it can be accessed by the LDS or STS instruction.

- 1. Any data transfer instruction is executed at the MA stage of the pipeline.
- 2. Any data transfer instruction does not modify the condition code bits of the DSR register.

**System control instructions:** The DSR, A0, X0, X1, Y0, and Y1 registers in the DSP unit can also be used as the CPU system registers. Accordingly, data transfer operations between these DSP system registers and general registers or memory can be executed by the STS and LDS instructions. These DSP system registers can be treated as the CPU system register such as PR, MACL and MACH and can use the same addressing modes.

# 3.4.1 General Registers

The DSP instructions 10 general registers in the 16 general registers as address pointers or index registers for double data transfers and single data transfers. In the following descriptions, another register function in the DSP instructions is also indicated within parentheses [].

Double data transfer instructions (X memory and Y memory are accessed simultaneously)
 In double data transfers, X memory Y memory can be accessed simultaneously. To specify X and Y memory addresses, two address pointers are supported.

Memory to be Accessed	d Address Pointer	Index Register
X memory (MOVX.W)	R4,R5[Ax]	R8 [lx]
Y memory (MOVY.W)	R6,R7[Ay]	R9 [ly]

Single data transfer instructions
 In single data transfer, any virtual address space can be accessed via the L bus. The following address pointers and index registers are used.

Address to be Accessed	Address Pointer	Index Register
Any virtual space (MOVS.W/L)	R4,R5, R2, R3[As]	R8 [Is]

	31	0
	R0	General registers (DSP mode)
	R1	Double data transfers:
	R2 [As2]	
	R3 [As3]	R4, 5 [Ax] : Address register set for the X memory
DataSheet4U.d	R4 [As0]	R8 [Ix] : Index register for X address register set Ax
DataSHEEL4U.C	R5 [As1, Ax	DO 7
	R6 [Ay0]	R6, 7 [Ay] : Address register set for the Y memory
	R7 [Ay1]	R9 [ly] : Index register for Y address register set Ay
	R8 [lx, ls]	
	R9 [ly]	Single data transfers:
	R0	R4, 5, 2, 3 [As] : Address register set for all data memories
	R10	R8 [Is] : Index register used for single data transfers
	R11	
	R12	
	R13	
	R14	
	R15	

Figure 3.5 General Registers (DSP Mode)

In assembler, R0 to R9 are used as symbols. In the DSP data transfer instructions, the following register names (alias) can also be used. In assembler, described as shown below.

Ix: .REG (R8)

Ix indicates the alias of register 8. Other aliases are shown below.

Ax0: .REG (R4)

Ax1: .REG (R5)

Ix: .REG (R8)

Ay0: .REG (R6)

Ay1: .REG(R7)

www.DataSheet4U.com

Iy: .REG (R9)

As0: .REG (R4); This definition is used for if the alias is required in the single data transfer

As1: .REG (R5); This definition is used for if the alias is required in the single data transfer

As2: .REG (R2)

As3: .REG (R3)

Is: .REG (R8); This definition is used for if the alias is required in the single data transfer

## 3.4.2 DSP Data Addressing

Table 3.10 shows the relationship between the double data transfer instructions and single data transfer instructions.

**Table 3.10 Overview of Data Transfer Instructions** 

	Double Data Transfer Instructions	Single Data Transfer Instructions
	MOVX.W, MOVY.W	MOVS.W, MOVS.L
Address register	Ax: R4, R5, Ay: R6, R7	As: R2, R3, R4, R5
Index register	Ix: R8, Iy: R9	Is: R8
Addressing	Nop/Inc (+2)/index addition: post-increment	Nop/Inc (+2, +4)/index addition: post-increment
	_	Dec (-2, -4): pre-decrement
Modulo addressing	Possible	Not possible
Data bus	XDB, YDB	LDB
Data length	16 bits (word)	16/32 bits (word/longword)
Bus conflict	No	Yes
Memory	X/Y data memory	Entire memory space
Source register	Dx, Dy: A0, A1	Ds: A0/A1, M0/M1, X0/X1, Y0/Y1, A0G, A1G
Destination register	Dx: X0/X1 Dy: Y0/Y1	Ds: A0/A1, M0/M1, X0/X1, Y0/Y1, A0G, A1G

**Addressing Mode for Double Data Transfer Instructions:** The double data transfer instructions supports the following three addressing modes.

- Non-update address register addressing
   The Ax and Ay registers are address pointers. They are not updated.
- Increment address register addressing
   The Ax and Ay registers are address pointers. After a data transfer, they are each incremented by 2 (post-increment).
- Addition index register addressing

The Ax and Ay registers are address pointers. After a data transfer, the value of the Ix or Iy register is added to each (post-increment). The double data transfer instructions do not supports decrement addressing mode. To perform decrementing, –2 is set in the index register and addition index register addressing is specified.

When using X/Y memory addressing, bit 0 of the address pointer is invalid. Accordingly, bit 0 of the address pointer and index register must be cleared to 0 in X/Y memory addressing. If 1 is written to the bit, correct operation cannot be guaranteed.

When accessing X and Y memories using the X and Y buses, the upper word of Ax and Ay are ignored. The result of Ay + 2 or Ay + Iy is stored in the lower word of Ay, while the upper word retains its original value. The Ax + 2 and Ax + Ix operations are executed in longword (32 bits) and the upper word may be changed according to the result.

**Addressing Mode for Single Data Transfer Instructions:** The following four kinds of addressing can be used with single data transfer instructions.

- Non-update address register addressing
   The As register is an address pointer. An access to @As is performed but As is not updated.
- Increment address register addressing:
   The As register is an address pointer. After an access to @As, the As register is incremented by 2 or 4 (post-increment).
- Addition index register addressing:
   The As register is an address pointer. After an access to @As, the value of the Is register is
- Decrement address register addressing:
   The As register is an address pointer. Before a data transfer, -2 or -4 is added to the As register (i.e. 2 or 4 is subtracted) (pre-decrement).

In single data transfer instructions, all bits in 32-bit address are valid.

added to the As register (post-increment).

### 3.4.3 Modulo Addressing

In double data transfer instructions, a modulo addressing can be used. The modulo addressing control instructions are listed in table 3.11. If the address pointer value reaches the preset modulo end address while a modulo addressing mode is specified, the address pointer value becomes the modulo start address

To control modulo addressing, the modulo register (MOD) extended in the DSP mode and the DMX and DMY bits of the SR register are used.

The MOD register is provided to set the start and end addresses of the modulo address area. The upper and lower words of the MOD register store modulo start address (MS) and modulo end address (ME), respectively. The LDC and STC instructions are extended for MOD register handling.

If the DMX bit of the SR register is set, the modulo addressing is specified for the X address register. If the DMY bit of the SR register is set, the modulo addressing is specified for the Y address register. Modulo addressing is valid for either the X or the Y address register, only; it cannot be set for both at the same time. Therefore, DMX and DMY cannot both be set simultaneously (if they are, the DMY setting will be valid). (In the future, this specification may be changed.) The DMX and MDY bits of the SR can be specified by the STC or LDC instruction for the SR register.

If an exception is accepted during modulo addressing, the MDX and MDY bits of the SR and MOD register must be saved. By restoring these register values, a control is returned to the modulo addressing after an exception handling.

**Table 3.11 Modulo Addressing Control Instructions** 

Instruc	ction	Operation	<b>Execution States</b>
STC	MOD,Rn	$MOD \to Rn$	1
STC.L	MOD,Rn	$Rn - 4 \rightarrow Rn, MOD \rightarrow (Rn)$	1
LDC	@Rn+,MOD	$(Rn) \rightarrow Rn, Rn + 4 \rightarrow Rn$	4
LDC	Rn+,MOD	$Rn \rightarrow MOD$	4

An example of the use of modulo addressing is shown below.

```
MOV.L #H'70047000, R10 ; Specify MS=H'7000 ME = H'7004
LDC Rn, MOD
                     :Specify ME:MS to MOD register
STC SR, R10
MOV.L #H'FFFFF3FF, R11
MOV.L #H'00000400, R12
AND R11, R10
OR R12, R10
                     ; Specify SR.MDX=1, SR.MDY=0, and
LDC R10, SR
                       X modulo addressing mode
MOV.L #H'A5007000, R14
MOVX.W @R4+,X0
                    ; R4: H'A5007000→ H'A5007002
MOVX.W @R4+,X0
                    ; R4: H'A5007002→ H'A5007004
MOVX.W @R4+.X0
                    ; R4: H'A5007004→ H'A5007000
                       (Matches to ME and MS is set)
                     ; R4: H'A5007000→ H'A5007002
MOVX.W @R4+,X0
```

The start and end addresses are specified in MS and ME, then the DMX or DMY bit is set to 1. When the X or Y data transfer instruction specified by the DMX or DMY is executed, the address register contents before updating are compared with ME\*, and if they match, start address MS is stored in the address register as the value after updating.

When the addressing type of the X/Y data transfer instruction is no-update, the X/Y data transfer instruction is not returned to MS even if they match ME. When the addressing type of the X/Y data transfer is adding index register, address pointer is may not match and exceed ME. In this case, the modulo start address is not set as the address pointer.

The maximum modulo size is 64 kbytes. This is sufficient to access the X and Y data memory.

Note: Not only with modulo addressing, but when X and Y data addressing is used, bit 0 is ignored. 0 must always be written to bit 0 of the address pointer, index register, MS, and ME.

www.DataSheet4U.com

#### 3.4.4 **Memory Data Formats**

Memory data formats that can be used in the DSP instructions are classified into word and longword. An address error will occur if word data starting from an address other than 2n is accessed by MOVS.W instruction or longword data starting from an address other than 4n is accessed by MOVS.L, LDS.L, or STS.L instruction. In such cases, the data accessed cannot be guaranteed

An address error will not occur if word data starting from an address other than 2n is accessed by the MOVX.W or MOVY.W instruction. When using the MOVX.W or MOVY.W instruction, an address must be specified on the boundary 2n. If an address is specified other than 2n, the data accessed cannot be guaranteed.

#### 3.4.5 **Instruction Formats of Double and Single Data Transfer Instructions**

The format of double data transfer instructions is shown in tables 3.12, and that of single data transfer instructions in table 3.13.

Table 3.12 Double Data Transfer Instruction Formats

## 3.5 DSP Data Operation Instructions

### 3.5.1 DSP Registers

There are eight data registers (A0, A1, X0, X1, Y0, Y1, M0 and M1) and one control register (DSR) as DSP registers (figure 3.3).

Four kinds of operation access the DSP data registers. The first is DSP data processing. When a DSP fixed-point arithmetic operation instruction uses A0 or A1 as the source register, it uses the guard bits (bits 39 to 32). When it uses A0 or A1 as the destination register, guard bits 39 to 32 are valid. When a DSP fixed-point arithmetic operation instruction uses a DSP register other than A0 or A1 as the source register, it sign-extends the source register value to bits 39 to 32. When it uses one of these registers as the destination register, bits 39 to 32 of the result are discarded.

The second kind of operation is an X or Y data transfer operation, MOVX.W, MOVY.W. This operation accesses the X and Y memories through the 16-bit X and Y data buses (figure 3.4). The register to be loaded or stored by this operation always comprises the upper 16 bits (bits 31 to 16). X0 or X1 can be the destination register of an X memory load and Y0 or Y1 can be the destination of a Y memory load, but no other register can be the destination register in this operation. When data is read into the upper 16 bits of a register (bits 31 to 16), the lower 16 bits of the register (bits 15 to 0) are automatically cleared. A0 and A1 can be stored in the X or Y memory by this operation, but no other registers can be stored.

The third kind of operation is a single-data transfer instruction, MOVS.W or MOVS.L. These instructions access any memory location through the LDB (figure 3.4). All DSP registers connect to the LDB and can be the source or destination register of the data transfer. These instructions have word and longword access modes. In word mode, registers to be loaded or stored by this instruction comprise the upper 16 bits (bits 31 to 16) for DSP registers except A0G and A1G. When data is loaded into a register other than A0G and A1G in word mode, the lower half of the register is cleared. When A0 or A1 is used, the data is sign-extended to bits 39–32 and the lower half is cleared. When A0G or A1G is the destination register in word mode, data is loaded into an 8-bit register, but A0 or A1 is not cleared. In longword mode, when the destination register is A0 or A1, it is sign-extended to bits 39 to 32.

The fourth kind of operation is system control instructions such as LDS, STS, LDS.L, or STS.L. The DSR, A0, X0, X1, Y0, and Y1 registers of the DSP register can be treated as system registers. For these registers, data transfer instructions between the CPU general registers and system registers or memory access instructions are supported.

Tables 3.14 and 3.15 show the data type of registers used in DSP instructions. Some instructions cannot use some registers shown in the tables because of instruction code limitations. For example, PMULS can use A1 as the source register, but cannot use A0. These tables ignore details of register selectability.

**Table 3.14 Destination Register in DSP Instructions** 

	Guard Bits		Reg	gister Bits		
Registers	Instruction	ıs	39 32	2 31	16 15	0
A0, A1	DSP operation	Fixed-point, PSHA, PMULS	Sign-extended	40-bit result		
		Integer, PDMSB	Sign-extended	24-bit result	Cleared	
		Logical, PSHL	Cleared	16-bit result	Cleared	
	Data	MOVS.W	Sign-extended	16-bit data	Cleared	
	transfer	MOVS.L	Sign-extended	32-bit data		
A0G, A1G	Data	MOVS.W	8-bit data	No update		
	transfer	MOVS.L	8-bit data	No update		
X0, X1 Y0, Y1	DSP operation	Fixed-point, PSHA, PMULS		32-bit result		
M0, M1 DataSheet4U.c		Integer, logical, PDMSB, PSHL		16-bit result	Cleared	
	Data	MOVX/Y.W, MOVS.W		16-bit data	Cleared	
	transfer	MOVS.L		32-bit data		

**Table 3.15 Source Register in DSP Operations** 

		Guard Bi	ts	Regi	ster Bits		
Registers	gisters Instructions		39	32	31 16	15	0
A0, A1	DSP operation	Fixed-point, PDMSB, PSHA	40-bit data				
		Integer	24-bit data				
		Logical, PSHL, PMULS			16-bit data		
	Data	MOVX/Y.W, MOVS.W	16-bit da		16-bit data		
	transfer	MOVS.L		;	32-bit data		
A0G, A1G	Data	MOVS.W	8-bit data				
	transfer	MOVS.L	8-bit data				
X0, X1 Y0, Y1	DSP Fixed-point, PDMSB, operation PSHA		Sign*	,	32-bit data		
Moʻ, M1		Integer	Sign*		16-bit data		
		Logical, PSHL, PMULS			16-bit data		
	Data	MOVS.W			16-bit data		
	transfer	MOVS.L		;	32-bit data		

Note: \* The data is sign-extended and input to the ALU.

The DSP unit incorporates the DSP status register (DSR) which is used as a control register. The DSR register stores the DSP data operation result (zero, negative, others). The DSR register also has the DC bit whose function is similar to the T bit of the CPU register. The DC bit functions as status flag. Conditional DSP data operations are controlled based on the DC bit. These operation control affects only the DSP unit instructions. In other words, these operations control affects only the DSP registers and does not affect address register update and CPU instructions such as load and store instructions. A condition to be reflected on the DC bit should be specified to the DC status selection bits (CS[2:0]).

The unconditional DSP type data operation instructions other than PMULS, MOVX, MOVY, and MOVS change the condition flag and DC bit. However, the CPU instructions including the MAC instruction do not modify the DC bit. In addition, conditional DSP data operation instructions do not modify the DSR.

Table 3.16 DSR Register Bits

Bits	Bit Name	Initial Value	R/W	Function
31 to 12	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
11 to 9	TS2 to	All 0	R/W	T Bit Status Selection
	TS0			Specifies the operation result status to be set in the T bit in the SR register if the TC bit is 1. If the S bit of the SR register is set to 1, an overflow is detected.
				000: Carry/borrow mode
				001: Negative value mode
				010: Zero mode
				011: Overflow mode
				100: Signed greater mode
				101: Signed greater than or equal to mode
				110: Reserved (setting prohibited)
				111: Reserved (setting prohibited)
8	TC	0	R/W	TC Bit
				0: The T bit of the SR register is not affected by the DSP instruction.
				1: The T bit of the SR register changes according to the TS bit of the DSR register while the DSP instruction is executed. Note, however, the T bit does not change during conditional DSP instruction execution.

	Bits	Bit Name	Initial Value	R/W	Function
•	7	GT	0	R/W	Signed Greater Bit
					Indicates that the operation result is positive (except 0), or that operand 1 is greater than operand 2
					1: Operation result is positive, or operand 1 is greater than operand 2
•	6	Z	0	R/W	Zero Bit
					Indicates that the operation result is zero (0), or that operand 1 is equal to operand 2
					1: Operation result is zero (0), or operands are equal
•	5	N	0	R/W	Negative Bit
					Indicates that the operation result is negative, or that operand 1 is smaller than operand 2
					1: Operation result is negative, or operand 1 is smaller than operand 2
ww.D	a <b>t</b> aSheet	4V.com	0	R/W	Overflow Bit
					Indicates that the operation result has overflowed
					1: Operation result has overflowed
•	3 to 1	CS	All 0	R/W	DC Bit Status Selection
					Designate the mode for selecting the operation result status to be set in the DC bit
					000: Carry/borrow mode
					001: Negative value mode
					010: Zero mode
					011: Overflow mode
					100: Signed greater mode
					101: Signed greater than or equal to mode
					110: Reserved (setting prohibited)
					111: Reserved (setting prohibited)

Bits	Bit Name	Initial Value	R/W	Function
0	DC	0	R/W	DSP Status Bit
				Sets the status of the operation result in the mode designated by the CS bits
				0: Designated mode status has not occurred (false)
				1: Designated mode status has occurred
				Indicates the operation result by carry or borrow regardless of the CS bit status after the PADDC or PSUBC instruction has been executed.

The DSR is assigned to the system registers. For the DSR, the following load and store instructions are supported.

```
STS DSR,Rn;

STS.L DSR,@-Rn;

www.DataSheetLDSORn,DSR;

LDS.L @Rn+,DSR;
```

If the DSR is read by the STS instruction, upper bits (bits 31 to 16) are all 0

### 3.5.2 DSP Instruction Set

DSP instructions are instructions for digital signal processing performed by the DSP unit. These instructions have a 32-bit instruction code, and multiple instructions can be executed in parallel. The instruction code is divided into an A field and B field; a parallel data transfer instruction is specified in the A field, and a single or double data operation instruction in the B field. Instructions can be specified independently, and are also executed independently.

B-field data operation instructions are of three kinds: double data operation instructions, conditional single data operation instructions, and unconditional single data operation instructions. The formats of the DSP operation instructions are shown in table 3.17. The respective operands are selected independently from the DSP registers. The correspondence between DSP instruction operands and registers is shown in table 3.18.

Parallel processing only instructions in the A field (without those in the B field) can be executed (transferring data in parallel without DSP data operation instructions).

**Table 3.17 DSP Instruction Formats** 

Туре		Instru	ction For	mats

X1	Yes	_	Yes	_	Yes	_	_
Y0		Yes	Yes	Yes	Yes	Yes	_
Y1	_	Yes	Yes		_	Yes	_

When writing parallel instructions, the B-field instruction is written first, followed by the A-field instruction. A sample parallel processing program using DSP instructions is shown in figure 3.6. Parallel processing only instructions in the A field (without those in the B field) can be executed (transferring data in parallel without DSP data operation instructions)

DCF PINC	M1, A1			MOVX.W @R5+R	3, X0	MOVY.W @R7+, Y1
PCMP	M1, M0			MOVX.W @R4,	X1	[NOPY]

Figure 3.6 Sample Parallel DSP Instruction Programw.DataSheet4U.com

Rev. 1.00, 02/04, page 112 of 804

Square brackets mean that the contents can be omitted.

The no operation instructions NOPX and NOPY can be omitted. For details on the B field in DSP instructions, refer to section 3.6.4, DSP Data Operation Instruction Set.

The DSR register condition code bit (DC) is always updated on the basis of the result of an unconditional ALU or shift operation instruction. Conditional instructions do not update the DC bit. Multiply instructions, also, do not update the DC bit. DC bit updating is performed by means of the CS[2:0] bits in the DSR register. The DC bit update rules are shown in table 3.19.

# **Table 3.19 DC Bit Update Definitions**

CS	S [2	:01	Condition Mode	Description
0	0	0	Carry or borrow mode	The DC bit is set if an ALU arithmetic operation generates a carry or borrow, and is cleared otherwise.
				When a PSHA or PSHL shift instruction is executed, the last bit data shifted out is copied into the DC bit.
				When an ALU logical operation is executed, the DC bit is always cleared.
0	0	1	Negative value mode	When an ALU or shift (PSHA) arithmetic operation is executed, the MSB of the result, including the guard bits, is copied into the DC bit.
				When an ALU or shift (PSHL) logical operation is executed, the MSB of the result, excluding the guard bits, is copied into the DC bit.
0	1	0	Zero value mode	The DC bit is set if the result of an ALU or shift operation is all-zeros, and is cleared otherwise.
.D <b>ag</b> a	She	et#U	Overflow mode	The DC bit is set if the result of an ALU or shift (PSHA) arithmetic operation exceeds the destination register range, excluding the guard bits, and is cleared otherwise.
				When an ALU or shift (PSHL) logical operation is executed, the DC bit is always cleared.
1	0	0	Signed greater-than mode	This mode is similar to signed greater-or-equal mode, but DC is cleared if the result is all-zeros.
				<pre>DC = ~{(negative value ^ over-range)   zero value};</pre>
				DC = 0; In case of logical operation
1	0	1	Signed greater-or- equal mode	If the result of an ALU or shift (PSHA) arithmetic operation exceeds the destination register range, including the guard bits (over-range), the definition is the same as in negative value mode. If the result is not over-range, the definition is the opposite of that in negative value mode.
				When an ALU or shift (PSHL) logical operation is executed, the DC bit is always cleared.
				DC = ~(negative value ^ over-range); In case of arithmetic operation
				DC = 0; In case of logical operation
1	1	0	Reserved (setting pr	ohibited)
1	1	1	Reserved (setting pr	ohibited)

### Conditional Operations and Data Transfer

Some instructions belonging to this class can be executed conditionally, as described earlier. The specified condition is valid only for the B field of the instruction, and is not valid for data transfer instructions for which a parallel specification is made. Examples are shown in figure 3.7.

```
DCT PADD X0, Y0, A0 MOVX.W @R4+, X0 MOVY.W A0, @R6+R9;
             When condition is True
             Before execution: X0=H'333333333, Y0=H'55555555, A0=H'123456789A,
                            R4=H'00008000, R6=H'00005000, R9=H'00000004,
                            (R4) = 1111 (R6) = 2222
             After execution: X0=H'11110000, Y0=H'55555555, A0=H'0088888888,
                            R4=H'00008002, R6=H'00005004, R9=H'00000004,
                            (H'00008000) = H'1111 (H'00008233) = H'2222
www.DataSheet4U.com
When condition is False
             Before execution: X0=H'333333333, Y0=H'55555555, A0=H'123456789A,
                            R4=H'00008000, R6=H'00005000, R9=H'00000004,
                            (R4) = 1111, (R6) = 2222
             After execution: X0=H'11110000, Y0=H'55555555, A0=H'123456789A,
                            R4=H'00008002, R6=H'00005004, R9=H'00000004,
                            (H'00008000) = H'1111 (H'00008233) = H'2222
```

Figure 3.7 Examples of Conditional Operations and Data Transfer Instructions

## Assignment of NOPX and NOPY Instruction Codes

When there is no data transfer instruction to be parallel-processed simultaneously with a DSP data operation instruction, an NOPX or NOPY instruction can be written as the data transfer instruction, or the instruction can be omitted. The instruction code is the same whether an NOPX or NOPY instruction is written or the instruction is omitted. When there in no DSP data operation instruction to be parallel-processed simultaneously with a data transfer instruction, an NOPX or NOPY instruction can be written or the instruction can be omitted. Examples of NOPX and NOPY instruction codes are shown in table 3.20.

Table 3.20 Examples of NOPX and NOPY Instruction Codes

## 3.5.3 DSP-Type Data Formats

This LSI has several different data formats that depend on the instruction. This section explains the data formats for DSP type instructions.

Figure 3.8 shows three DSP-type data formats with different binary point positions. A CPU-type data format with the binary point to the right of bit 0 is also shown for reference.

The DSP-type fixed point data format has the binary point between bit 31 and bit 30. The DSP-type integer format has the binary point between bit 16 and bit 15. The DSP-type logical format does not have a binary point. The valid data lengths of the data formats depend on the instruction and the DSP register.

RENESAS

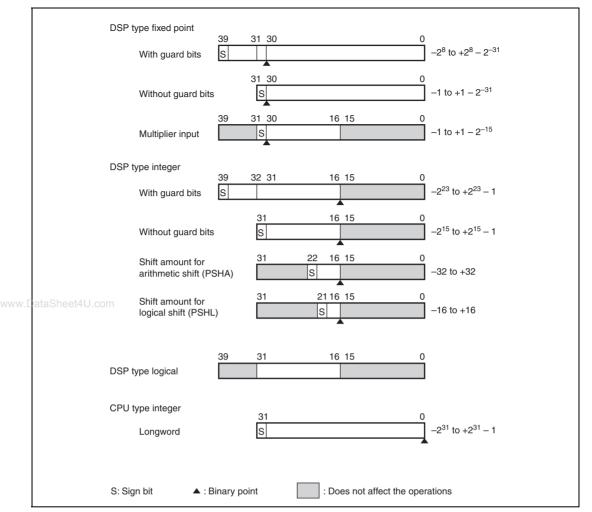

Figure 3.8 Data Formats

The shift amount for the arithmetic shift (PSHA) instruction has a 7-bit field that can represent values from -64 to +63, but -32 to +32 are valid numbers for the instruction. Also the shift amount for a logical shift operation has a 6-bit field, but -16 to +16 are valid numbers for the instruction. The results when an invalid shift amount is specified cannot be guaranteed.

### 3.5.4 ALU Fixed-Point Arithmetic Operations

Figure 3.9 shows the ALU fixed-point arithmetic operation flow. Table 3.21 shows the variation of this type of operation and table 3.22 shows the correspondence between each operand and registers.

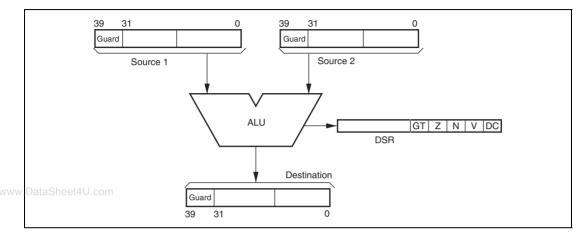

Figure 3.9 ALU Fixed-Point Arithmetic Operation Flow

Note: The ALU fixed-point arithmetic operations are basically 40-bit operation; 32 bits of the base precision and 8 bits of the guard-bit parts. So the signed bit is copied to the guard-bit parts when a register not providing the guard-bit parts is specified as the source operand. When a register not providing the guard-bit parts is specified as a destination operand, the lower 32 bits of the operation result are input into the destination register.

ALU fixed-point operations are executed between registers. Each source and destination operand are selected independently from one of the DSP registers. When a register providing guard bits is specified as an operand, the guard bits are activated for this type of operation. These operations are executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

**Table 3.21 Variation of ALU Fixed-Point Operations** 

Mnemonic	Function	Source 1	Source 2	Destination
PADD	Addition	Sx	Sy	Dz or Du
PSUB	Subtraction	Sx	Sy	Dz or Du
PADDC	Addition with carry	Sx	Sy	Dz
PSUBC	Subtraction with borrow	Sx	Sy	Dz
PCMP	Comparison	Sx	Sy	_
PCOPY	Data copy	Sx	All 0	Dz
		All 0	Sy	Dz
PABS	Absolute	Sx	All 0	Dz
		All 0	Sy	Dz
PNEG	Negation	Sx	All 0	Dz
		All 0	Sy	Dz
PCLR	Clear	All 0	All 0	Dz

Table 3.22 Correspondence between Operands and Registers

Register	Sx	Sy	Dz	Du	
A0	Yes	_	Yes	Yes	
A1	Yes	_	Yes	Yes	
MO	_	Yes	Yes	_	
M1	_	Yes	Yes	_	
X0	Yes	_	Yes	Yes	
X1	Yes	_	Yes	_	
Y0	_	Yes	Yes	Yes	
Y1	_	Yes	Yes	_	

As shown in figure 3.10, data loaded from the memory at the MA stage to X0 by the data transfer instruction (MOVX.W @R4+,X0) which is programmed at the same line as the ALU operation (PADD X0,Y0,A0) , is not used as a source operand for this operation, even though the destination operand X0 of the data load operation is identical to the source operand of the ALU operation. In this case, results of previous operation (MOVX.W @R4+,X0) are used as the source operands for the ALU operation, and then updated as the destination operand X0 of the data transfer instruction (MOVX.W @R4+,X0).

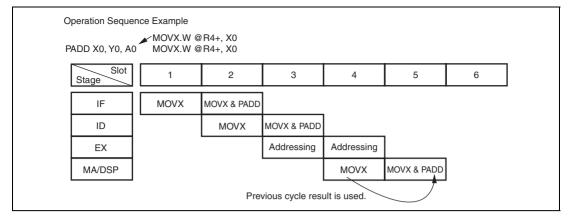

Figure 3.10 Operation Sequence Example

Every time an ALU arithmetic operation is executed, the DC, N, Z, V, and GT bits in DSR are basically updated in accordance with the operation result. However, in case of a conditional operation, they are not updated even though the specified condition is true and the operation is executed. In case of an unconditional operation, they are always updated in accordance with the operation result. The definition of a DC bit is selected by CS[2:0] (condition selection) bits in DSR. The DC bit result is as follows:

Carry or Borrow Mode: CS[2:0] = B'000: The DC bit indicates that carry or borrow is generated from the most significant bit of the operation result, except the guard-bit parts. Some examples are shown in figure 3.11. This mode is the default condition. When the input data is negative in a PABS or PNEG instruction, carry is generated.

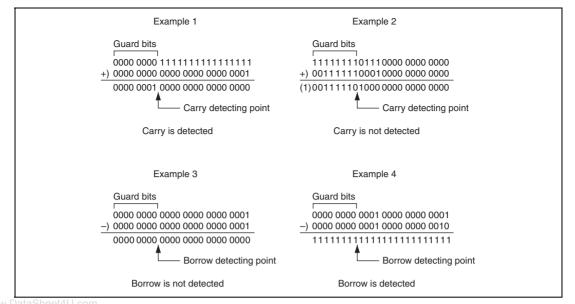

Figure 3.11 DC Bit Generation Examples in Carry or Borrow Mode

**Negative Value Mode:** CS[2:0] = B'001: The DC flag indicates the same value as the MSB of the operation result. When the result is a negative number, the DC bit shows 1. When it is a positive number, the DC bit shows 0. The ALU always executes 40-bit arithmetic operation, so the sign bit to detect whether positive or negative is always got from the MSB of the operation result regardless of the destination operand. Some examples are shown in figure 3.12.

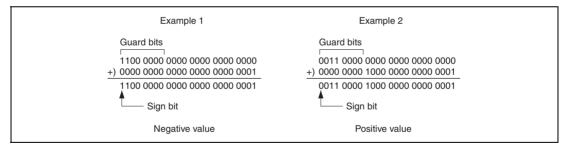

Figure 3.12 DC Bit Generation Examples in Negative Value Mode

**Zero Value Mode:** CS[2:0] = B'010: The DC flag indicates whether the operation result is 0 or not. When the result is 0, the DC bit shows 1. When it is not 0, the DC bit shows 0.

**Overflow Mode:** CS[2:0] = B'011: The DC bit indicates whether or not overflow occurs in the result. When an operation yields a result beyond the range of the destination register, except the guard-bit parts, the DC bit is set. Even though guard bits are provided in the destination register, the DC bit always indicates the result of when no guard bits are provided. So, the DC bit is always

set if the guard-bit parts are used for large number representation. Some DC bit generation examples in overflow mode are shown in figure 3.13.

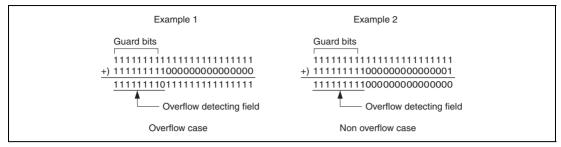

Figure 3.13 DC Bit Generation Examples in Overflow Mode

Signed Greater Than Mode: CS[2:0] = B'100: The DC bit indicates whether or not the source 1 data (signed) is greater than the source 2 data (signed) as the result of compare operation PCMP. Therefore, the PCMP operation should be executed before the conditional operation is executed under this condition mode. This mode is similar to the Negative Value Mode described before, because the result of a compare operation is a positive value if the source 1 data is greater than the source 2 data. However, the signed bit of the result shows a negative value if the compare operation yields a result beyond the range of the destination operand, including the guard-bit parts (called "Over-range"), even though the source 1 data is greater than the source 2 data. The DC bit is updated concerning this type of special case in this condition mode. The equation below shows the definition of getting this condition:

When the PCMP operation is executed under this condition mode, the result of the DC bit is the same as the T bit's result of the CMP/GT operation of the CPU instruction.

Signed Greater Than or Equal Mode: CS[2:0] = B'101: The DC bit indicates whether the source 1 data (signed) is greater than or equal to the source 2 data (signed) as the result of compare operation PCMP. Therefore, the PCMP operation should be executed before the conditional operation is executed under this condition mode. This mode is similar to the Signed Greater Than Mode described before but the equal case is also included in this mode. The equation below shows the definition of getting this condition:

When the PCMP operation is executed under this condition mode, the result of the DC bit is the same as the T bit's result of a CMP/GE operation of the CPU instruction.

The N bit always indicates the same state as the DC bit set in negative value mode by the CS[2:0] bits. See the negative value mode part above. The Z bit always indicates the same state as the DC bit set in zero value mode by the CS[2:0] bits. See the zero value mode part above. The V bit www.DataSheet4U.com

always indicates the same state as the DC bit set in overflow mode by the CS[2:0] bits. See the overflow mode part above. The GT bit always indicates the same state as the DC bit set in signed greater than mode by the CS[2:0] bits. See the signed greater than mode part above.

Note: The DC bit is always updated as the carry flag for 'PADDC' and is always updated as the carry/borrow flag for 'PSUBC' regardless of the CS[2:0] state.

#### Overflow Protection

The S bit in SR is effective for any ALU fixed-point arithmetic operations in the DSP unit. See section 3.5.11, Overflow Protection, for details.

## 3.5.5 ALU Integer Operations

Figure 3.14 shows the ALU integer arithmetic operation flow. Table 3.23 shows the variation of this type of operation. The correspondence between each operand and registers is the same as ALU fixed-point operations as shown in table 3.22.

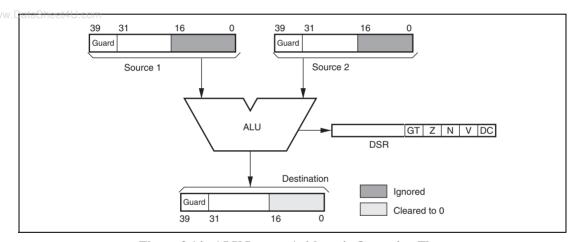

Figure 3.14 ALU Integer Arithmetic Operation Flow

**Table 3.23 Variation of ALU Integer Operations** 

Mnemonic	Function	Source 1	Source 2	Destination
PINC	Increment by 1	Sx	+1	Dz
		+1	Sy	Dz
PDEC	Decrement by 1	Sx	-1	Dz
		<del>-1</del>	Sy	Dz

The ALU integer operations are basically 24-bit operation, the upper 16 bits of the base Note: precision and 8 bits of the guard-bits parts. So the signed bit is copied to the guard-bit parts when a register not providing the guard-bit parts is specified as the source operand. When a register not providing the guard-bit parts is specified as a destination operand, the upper word excluding the guard bits of the operation result are input into the destination register.

In ALU integer arithmetic operations, the lower word of the source operand is ignored and the lower word of the destination operand is automatically cleared. The guard-bit parts are effective in integer arithmetic operations if they are supported. Others are basically the same operation as ALU fixed-point arithmetic operations. As shown in table 3.23, however, this type of operation provides two kinds of instructions only, so that the second operand is actually either +1 or -1. When a word data is loaded into one of the DSP unit's registers, it is input as an upper word data. When a register providing guard bits is specified as an operand, the guard bits are also activated. These operations, as well as ALU fixed-point arithmetic operations, are executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

Every time an ALU arithmetic operation is executed, the DC, N, Z, V, and GT bits in DSR are basically updated in accordance with the operation result. This is the same as ALU fixed-point arithmetic operations but the lower word of each source and destination operand is not used in order to generate them. See section 3.5.4, ALU Fixed-Point Arithmetic Operations, for details.

In case of a conditional operation, they are not updated even though the specified condition is true and the operation is executed. In case of an unconditional operation, they are always updated in accordance with the operation result. See section 3.5.4, ALU Fixed-Point Arithmetic Operations, for details.

#### Overflow Protection

The S bit in SR is effective for any ALU integer arithmetic operations in DSP unit. See section 3.5.11, Overflow Protection, for details.

### 3.5.6 ALU Logical Operations

Figure 3.15 shows the ALU logical operation flow. Table 3.24 shows the variation of this type of operation. The correspondence between each operand and registers is the same as the ALU fixed-point arithmetic operations as shown in table 3.21.

The ALU logical operation is executed between registers. Each source operand and destination operand is selected independently from one of the DSP registers. As shown in figure 3.15, this type of operation uses only the upper word of each operand. The lower word and guard-bit parts are ignored for the source operand and those of the destination operand are automatically cleared. These operations are also executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

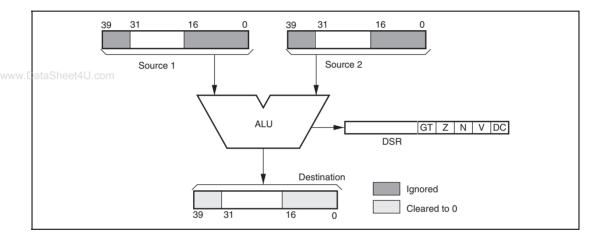

Figure 3.15 ALU Logical Operation Flow

Mnemonic	Function	Source 1	Source 2	Destination
PAND	Logical AND	Sx	Sy	Dz
POR	Logical OR	Sx	Sy	Dz
PXOR	Logical exclusive OR	Sx	Sy	Dz

Every time an ALU logical operation is executed, the DC, N, Z, V, and GT bits in the DSR register are basically updated in accordance with the operation result. In case of a conditional operation, they are not updated even though the specified condition is true and the operation is executed. In case of an unconditional operation, they are always updated in accordance with the operation result. The definition of the DC bit is selected by the CS[2:0] (DC bit condition selection) bits in DSR. The DC bit result is:

Carry or Borrow Mode: CS[2:0] = B'000: The DC bit is always cleared to 0.

Negative Value Mode: CS[2:0] = B'001: Bit 31 of the operation result is loaded into the DC bit.

**Zero Value Mode:** CS[2:0] = B'010: The DC bit is set to 1 when the operation result is zero; otherwise it is cleared to 0.

Overflow Mode: CS[2:0] = B'011: The DC bit is always cleared to 0.

Signed Greater Than Mode: CS[2:0] = B'100: The DC bit is always cleared to 0.

**Signed Greater Than or Equal Mode: CS[2:0] = B'101:** The DC bit is always cleared to 0.

The N bit always indicates the same state as the DC bit set in negative value mode by the CS[2:0] bits. See the negative value mode part above. The Z bit always indicates the same state as the DC bit set in zero value mode by the CS[2:0] bits. See the zero value mode part above. The V bit always indicates the same state as the DC bit set in overflow mode by the CS[2:0] bits. See the overflow mode part above. The GT bit always indicates the same state as the DC bit set in signed greater than mode by the CS[2:0] bits. See the signed greater than mode part above.

## 3.5.7 Fixed-Point Multiply Operation

Figure 3.16 shows the fixed-point multiply operation flow. Table 3.25 shows the variation of this type of operation and table 3.26 shows the correspondence between each operand and registers. The multiply operation of the DSP unit is single-word signed single-precision multiplication. The fixed-point multiply operations are executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

If a double-precision multiply operation is needed, the CPU double-word multiply instructions can be made of use.

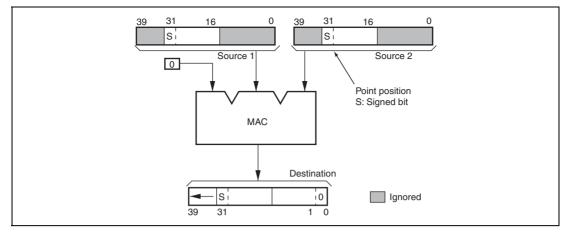

Figure 3.16 Fixed-Point Multiply Operation Flow

**Table 3.25 Variation of Fixed-Point Multiply Operation** 

Dat Mnemonic	Function	Source 1	Source 2	Destination
PMULS	Signed multiplication	Se	Sf	Dg

Table 3.26 Correspondence between Operands and Registers

Register	Se	Sf	Dg
A0	_	_	Yes
A1	Yes	Yes	Yes
MO	_	_	Yes
M1	_	_	Yes
X0	Yes	Yes	_
X1	Yes	_	_
Y0	Yes	Yes	_
Y1	_	Yes	_

Note: The multiply operations basically generate 32-bit operation results. So when a register providing the guard-bit parts are specified as a destination operand, the guard-bit parts will copy bit 31 of the operation result.

The multiply operation of the DSP unit side is not integer but fixed-point arithmetic. So, the upper words of each multiplier and multiplicand are input into a MAC unit as shown in figure 3.16. In the CPU instruction multiply operations, the lower words of both source operands are input into a MAC unit. The operation result is also different from the CPU's case. The CPU instruction multiply operation result is aligned to the LSB of the destination, but the fixed-point multiply operation result of DSP unit is aligned to the MSB, so that the LSB of the fixed-point multiply operation result is always 0.

Rev. 1.00, 02/04, page 127 of 804

Multiply is always unconditional, but does not affect any condition code bits, DC, N, Z, V, and GT, in DSR.

#### • Overflow Protection

The S bit in SR is effective for this multiply operation in the DSP unit. See section 3.5.11, Overflow Protection, for details.

If the S bit is 0, overflow occurs only when H'8000\*H'8000 ((-1.0)\*(-1.0)) operation is executed as signed fixed-point multiply. The result is H'00~8000~0000 but it does not mean (+1.0). If the S bit is 1, overflow is prevented and the result is H'00~7FFF FFFF.

### 3.5.8 Shift Operations

Shift operations barrel shift and can use either register or immediate value as the shift amount operand. Other source and destination operands are specified by the register. There are two kinds of shift operations of arithmetic and logical shifts. Table 3.27 shows the variation of this type of operation. The correspondence between each operand and registers, except for immediate operands, is the same as the ALU fixed-point operations as shown in table 3.21.

**Table 3.27 Variation of Shift Operations** 

Mnemonic	Function	Source 1	Source 2	Destination
PSHA Sx, Sy, Dz	Arithmetic shift	Sx	Sy	Dz
PSHL Sx, Sy, Dz	Logical shift	Sx	Sy	Dz

**Arithmetic Shift:** Figure 3.17 shows the arithmetic shift operation flow.

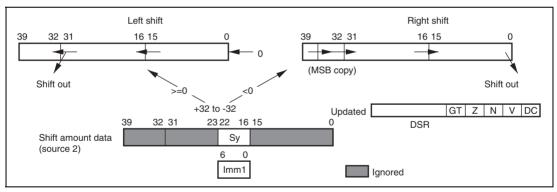

Figure 3.17 Arithmetic Shift Operation Flow

Note: The arithmetic shift operations are basically 40-bit operation, that is, the 32 bits of the base precision and eight bits of the guard-bit parts. So the signed bit is copied to the guard-bit parts when a register not providing the guard-bit parts is specified as the source operand. When a register not providing the guard-bit parts is specified as a destination operand, the lower 32 bits of the operation result are input into the destination register.

In this arithmetic shift operation, all bits of the source 1 and destination operands are activated. The shift amount is specified by the source 2 operand as an integer data. The source 2 operand can be specified by either a register or immediate operand. The available shift are 12 from

+32. Here, a negative value means the right shift, and a positive value means the left shift. It is possible for any source 2 operand to specify from –64 to +63 but the result is unknown if an invalid shift value is specified. In case of a shift with an immediate operand instruction, the source 1 operand must be the same register as the destination's. This operation is executed in the DSP stage, as shown in figure 3.10 as well as in ALU fixed-point arithmetic operations. The DSP stage is the same stage as the MA stage in which memory access is performed.

Every time an arithmetic shift operation is executed, the DC, N, Z, V, and GT bits in DSR are basically updated in accordance with the operation result. In case of a conditional operation, they are not updated even though the specified condition is true and the operation is executed. In case of an unconditional operation, they are always updated in accordance with the operation result. The definition of the DC bit is selected by the CS[2:0] (DC bit condition selection) bits in DSR. The DC bit result is:

- Carry or Borrow Mode: CS[2:0] = B'000
   The DC bit indicates the last shifted out data as the operation result.
- 2. Negative Value Mode: CS[2:0] = B'001

The DC bit is set to 1 when the operation result is a negative value, and cleared to 0 when the operation result is zero or a positive value.

- 3. Zero Value Mode: CS[2:0] = B'010

  The DC bit is set to 1 when the operation result is zero; otherwise it is cleared to 0.
- 4. Overflow Mode: CS[2:0] = B'011

  The DC bit is set to 1 when an overflow occurs.
- 5. Signed Greater Than Mode: CS[2:0] = B'100 The DC bit is always cleared to 0.
- 6. Signed Greater Than or Equal Mode: CS[2:0] = B'101 The DC bit is always cleared to 0.

The N bit always indicates the same state as the DC bit set in negative value mode by the CS[2:0] bits. See the negative value mode part above. The Z bit always indicates the same state as the DC bit set in zero value mode by the CS[2:0] bits. See the zero value mode part above. The V bit always indicates the same state as the DC bit set in overflow mode by the CS[2:0] bits. See the overflow mode part above. The GT bit always indicates the same state as the DC bit set in signed greater than mode by the CS[2:0] bits. See the signed greater than mode part above.

Overflow Protection

The S bit in SR is also effective for arithmetic shift operation in the DSP unit. See section 3.5.11, Overflow Protection, for details.

**Logical Shift:** Figure 3.18 shows the logical shift operation flow.

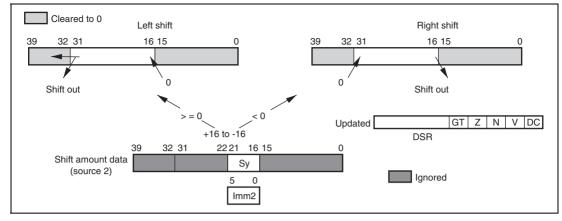

Figure 3.18 Logical Shift Operation Flow

As shown in figure 3.18, the logical shift operation uses the upper word of the source 1 operand and the destination operand. The lower word and guard-bit parts are ignored for the source operand and those of the destination operand are automatically cleared as in the ALU logical operations. The shift amount is specified by the source 2 operand as an integer data. The source 2 operand can be specified by either the register or immediate operand. The available shift range is from –16 to +16. Here, a negative value means the right shift, and a positive value means the left shift. It is possible for any source 2 operand to specify from –32 to +31, but the result is unknown if an invalid shift value is specified. In case of a shift with an immediate operand instruction, the source 1 operand must be the same register as the destination's. These operations are executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

Every time a logical shift operation is executed, the DC, N, Z, V, and GT bits in DSR are basically updated in accordance with the operation result. In case of a conditional operation, they are not updated even though the specified condition is true and the operation is executed. In case of an unconditional operation, they are always updated in accordance with the operation result. The definition of the DC bit is selected by the CS[2:0] (DC bit condition selection) bits in DSR. The DC bit result is:

- Carry or Borrow Mode: CS[2:0] = B'000
   The DC bit indicates the last shifted out data as the operation result.
- 2. Negative Value Mode: CS[2:0] = B'001
  Bit 31 of the operation result is loaded into the DC bit.
- 3. Zero Value Mode: CS[2:0] = B'010

  The DC bit is set to 1 when the operation result is zero; otherwise it is cleared to 0.

4. Overflow Mode: CS[2:0] = B'011 The DC bit is always cleared to 0.

5. Signed Greater Than Mode: CS[2:0] = B'100

The DC bit is always cleared to 0.

6. Signed Greater Than or Equal Mode: CS[2:0] = B'101

The DC bit is always cleared to 0.

The N bit always indicates the same state as the DC bit set in negative value mode by the CS[2:0] bits. See the negative value mode part above. The Z bit always indicates the same state as the DC bit set in zero value mode by the CS[2:0] bits. See the zero value mode part above. The V bit always indicates the same state as the DC bit set in overflow mode by the CS[2:0] bits, but it is always cleared in this operation. So is the GT bit.

## 3.5.9 Most Significant Bit Detection Operation

The PDMSB, most significant bit detection operation, is used to calculate the shift amount for normalization. Figure 3.19 shows the PDMSB operation flow and table 3.28 shows the operation definition. Table 3.29 shows the possible variations of this type of operation. The correspondence between each operand and registers is the same as for ALU fixed-point operations, as shown in table 3.21.

Note: The result of the MSB detection operation is basically 24 bits as well as ALU integer operation, the upper 16 bits of the base precision and eight bits of the guard-bit parts. When a register not providing the guard-bit parts is specified as a destination operand, the upper word of the operation result is input into the destination register.

As shown in figure 3.19, the PDMSB operation uses all bits as a source operand, but the destination operand is treated as an integer operation result because shift amount data for normalization should be integer data as described in section 3.5.8, Arithmetic Shift. These operations are executed in the DSP stage, as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

Every time a PDMSB operation is executed, the DC, N, Z, V, and GT bits in DSR are basically updated in accordance with the operation result. In case of a conditional operation, they are not updated, even though the specified condition is true, and the operation is executed. In case of an unconditional operation, they are always updated with the operation result.

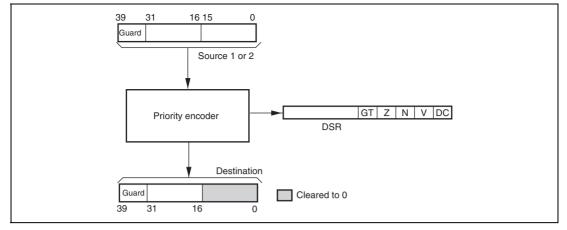

Figure 3.19 PDMSB Operation Flow

The definition of the DC bit is selected by the CS[2:0] (DC bit condition selection) bits in DSR. The DC bit result is

ataSneet4U.com

Carry or Borrow Mode: CS[2:0] = B'000: The DC bit is always cleared to 0.

**Negative Value Mode:** CS[2:0] = B'001: The DC bit is set to 1 when the operation result is a negative value, and cleared to 0 when the operation result is zero or a positive value.

**Zero Value Mode:** CS[2:0] = B'010: The DC bit is set to 1 when the operation result is zero; otherwise it is cleared to 0.

Overflow Mode: CS[2:0] = B'011: The DC bit is always cleared to 0.

**Signed Greater Than Mode:** CS[2:0] = B'100: The DC bit is set to 1 when the operation result is a positive value; otherwise it is cleared to 0.

Signed Greater Than or Equal Mode: CS[2:0] = B'101: The DC bit is set to 1 when the operation result is zero or a positive value; otherwise it is cleared to 0.

Note: \* means don't care.

Table 3.29 Variation of PDMSB Operation

Mnemonic	Function	Source	Source 2	Destination
PDMSB	MSB detection	Sx	_	Dz
		_	Sy	Dz

The N bit always indicates the same state as the DC bit set in negative value mode by the CS[2:0] bits. See the negative value mode part above. The Z bit always indicates the same state as the DC bit set in zero value mode by the CS[2:0] bits. See the zero value mode part above. The V bit is always cleared. The GT bit always indicates the same state as the DC bit set in signed greater than mode by the CS[2:0] bits. See the signed greater than mode part above.

### 3.5.10 Rounding Operation

The DSP unit provides the function that rounds from 32 bits to 16 bits. In case of providing guard-bit parts, it rounds from 40 bits to 24 bits. When a round instruction is executed, H'00008000 is added to the source operand data and then, the lower word is cleared. Figure 3.20 shows the rounding operation flow and figure 3.21 shows the operation definition. Table 3.30 shows the variation rounding operation. The correspondence between each operand and registers is the same as ALU fixed-point operations as shown in table 3.21.

As shown in figure 3.21, the rounding operation uses full-size data for both source and destination operands. These operations are executed in the DSP stage as shown in figure 3.10. The DSP stage is the same stage as the MA stage in which memory access is performed.

The rounding operation is always executed unconditionally, so that the DC, N, Z, V, and GT bits in DSR are always updated in accordance with the operation result. The definition of the DC bit is selected by the CS[2:0] (DC bit condition selection) bits in DSR. The result of these condition code bits is the same as the ALU-fixed point arithmetic operations.

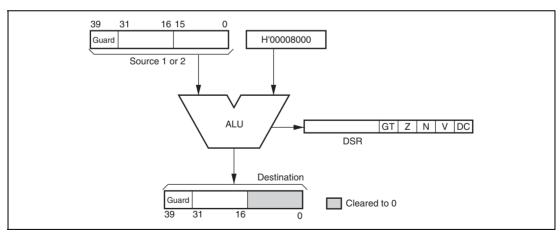

Figure 3.20 Rounding Operation Flow

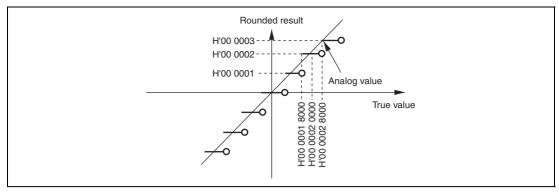

Figure 3.21 Definition of Rounding Operation

**Table 3.30 Variation of Rounding Operation** 

Mnemonic	Function	Source 1	Source 2	Destination	
PRND	Rounding	Sx	_	Dz	
w.DataSheet4U.com		_	Sy	Dz	

Overflow Protection

The S bit in SR is effective for any rounding operations in the DSP unit. See section 3.5.11, Overflow Protection, for details.

#### 3.5.11 Overflow Protection

The S bit in SR is used as the overflow protection enable bit. The S bit is effective for any arithmetic operations executed in the DSP unit, including the CPU instruction multiply and MAC operations. The arithmetic operation overflows when the operation result exceeds the range of two's complement representation without guard-bit parts. Table 3.31 shows the definition of overflow protection for fixed-point arithmetic operations, including fixed-point multiplication described in section 3.5.7, Fixed-Point Multiply Operation. Table 3.32 shows the definition of overflow protection for integer arithmetic operations. The lower word of the saturation value of the integer arithmetic operation is don't care. Lower word value cannot be guaranteed.

When the overflow protection is effective, overflow never occurs. So, the V bit is cleared, and the DC bit is also cleared when the overflow mode is selected by the CS[2:0] bits.

**Table 3.31 Definition of Overflow Protection for Fixed-Point Arithmetic Operations** 

Sign	Overflow Condition	Fixed Value	Hex Representation
Positive	Result > 1 - 2 <sup>-31</sup>	$1-2^{-31}$	00 7FFF FFFF
Negative	Result < -1	<b>–1</b>	FF 8000 0000

**Table 3.32 Definition of Overflow Protection for Integer Arithmetic Operations** 

Sign	Overflow Condition	Fixed Value	Hex Representation
Positive	Result > 2 <sup>15</sup> – 1	2 <sup>15</sup> – 1	00 7FFF ****
Negative	Result < -2 <sup>15</sup>	<b>-2</b> <sup>15</sup>	FF 8000 ****

Note: \* means don't care.

#### 3.5.12 Local Data Move Instruction

The DSP unit of this LSI provides additional two independent registers, MACL and MACH, in order to support CPU instruction multiply/MAC operations. They can be also used as temporary storage registers by local data move instructions between MACH/L and other DSP registers. Figure 3.22 shows the flow of seven local data move instructions. Table 3.33 shows the variation of this type of instruction.

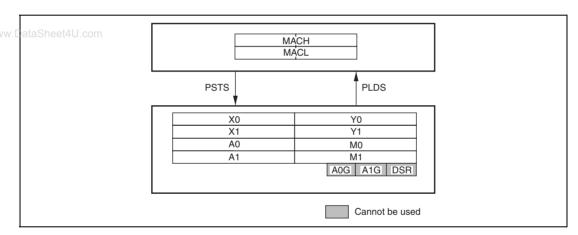

Figure 3.22 Local Data Move Instruction Flow

**Table 3.33 Variation of Local Data Move Operations** 

Mnemonic	Function	Operand
PLDS	Data move from DSP register to MACL/MACH	Dz
PSTS	Data move from MACL/MACH to DSP register	Dz

This instruction is very similar to other transfer instructions. If either the A0 or A1 register is specified as the destination operand of PSTS, the signed bit is sign-extended and copied into the corresponding guard-bit parts, A0G or A1G. The DC bit in DSR and other condition code bits are not updated regardless of the instruction result. This instruction can operate with MOVX and MOVY in parallel.

### 3.5.13 Operand Conflict

When an identical destination operand is specified with multiple parallel instructions, data conflict occurs. Table 3.34 shows the correspondence between each operand and registers.

Table 3.34 Correspondence between Operands and Registers

		X-Memory Load Instructions		Y-Memory Load Instructions		6-Operand ALU Instructions		3-Operand Multiply Instructions		3-Operand ALU Instructions						
		Ax	lx	Dx	Ау	ly	Dy	Sx	Sy	Du	Se	Sf	Dg	Sx	Sy	Dz
DSP Registers	A0							*1		*2			*2	*1		*1
	A1							*1		*2	*1	*1	*2	*1		*1
	M0								*1				*1		*1	*1
	M1								*1				*1		*1	*1
	X0			*2				*1		*2	*1	*1		*1		*2
ataSheet4U	<b>X</b> 1m			*2				*1			*1			*1		*2
	Y0						*2		*1	*2	*1	*1			*1	*2
	Y1						*2		*1			*1			*1	*2

Notes: 1. Registers available for operands

2. Registers available for operands (when there is operand conflict)

There are three cases of operand conflict problems.

- When ALU and multiply instructions specify the same destination operand (Du and Dg)
- When X-memory load and ALU instructions specify the same destination operand (Dx and Du, or Dz)
- When Y-memory load and ALU instructions specify the same destination operand (Dy and Du, or Dz)

In these cases above, the result is not guaranteed.

Note: \* If guard bit registers A0G and A1G are specified in source operand Ds, the data is output to the LDB[7:0] bus and the sign bit is copied into the upper bits, [31:8].

The correspondence between DSP data transfer operands and registers is shown in table 3.38.

Table 3.38 Correspondence between DSP Data Transfer Operands and Registers

Notes: 1. For details, refer to the SH-3/SH-3E/SH3-DSP Programming Manual.

2. Instructions in the hatched areas are DSP extended instructions. These instructions can be executed only when the DSP bit in the SR register is set to 1.

# Section 4 Exception Handling

Exception handling is separate from normal program processing, and is performed by a routine separate from the normal program. For example, if an attempt is made to execute an undefined instruction code or an instruction protected by the CPU processing mode, a control function may be required to return to the source program by executing the appropriate operation or to report an abnormality and carry out end processing. In addition, a function to control processing requested by LSI on-chip modules or an LSI external module to the CPU may also be required.

Transferring control to a user-defined exception handling routine and executing the process to support the above functions are called exception handling. This LSI has two types of exceptions: general exceptions and interrupts. The user can execute the required processing by assigning exception handling routines corresponding to the required exception processing and then return to the source program.

A reset input can terminate the normal program execution and pass control to the reset vector after register initialization. This reset operation can also be regarded as an exception handling. This section describes an overview of the exception handling operation. Here, general exceptions and interrupts are referred to as exception handling. For interrupts, this section describes only the process executed for interrupt requests. For details on how to generate an interrupt request, refer to section 8, Interrupt Controller (INTC).

## 4.1 Register Descriptions

There are four registers for exception handling. A register with an undefined initial value should be initialized by the software. Refer to section 27, List of Registers, for the register addresses and register states in each process.

- TRAPA exception register (TRA)
- Exception event register (EXPEVT)
- Interrupt event register 2 (INTEVT2)
- Exception address register (TEA)

Figure 4.1 shows the bit configuration of each register.

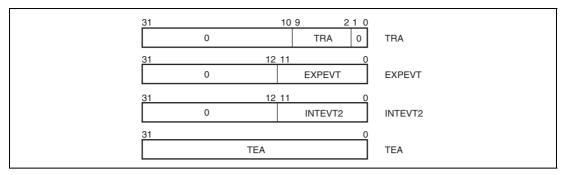

Figure 4.1 Register Bit Configuration

### 4.1.1 TRAPA Exception Register (TRA)

TRA is assigned to address HTFFFFFD0 and consists of the 8-bit immediate data (imm) of the TRAPA instruction. TRA is automatically specified by the hardware when the TRAPA instruction is executed. Only bits 9 to 2 of the TRA can be re-written using the software.

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
9 to 2	TRA	_	R/W	8-bit Immediate Data
1	_	All 0	R	Reserved
0				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

### **4.1.2** Exception Event Register (EXPEVT)

EXPEVT is assigned to address H'FFFFFD4 and consists of a 12-bit exception code. Exception codes to be specified in EXPEVT are those for resets and general exceptions. These exception codes are automatically specified by the hardware when an exception occurs. Only bits 11 to 0 of EXPEVT can be re-written using the software.

Bit	Bit Name	Initial Value	R/W	Description
31 to 12 — All 0		All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
11 to 0	EXPEVT	*	R/W	12-bit Exception Code

Note: Initialized to H'000 at power-on reset and H'020 at manual reset.

### www.Da4.1.3et4U Interrupt Event Register 2 (INTEVT2)

INTEVT2 is assigned to address H'A4000000 and consists of a 12-bit exception code. Exception codes to be specified in INTEVT2 are those for interrupt requests. These exception codes are automatically specified by the hardware when an exception occurs. INTEVT2 cannot be modified using the software.

Bit	Bit Name	Initial Value	R/W	Description
31 to 12 — All 0		All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0.
11 to 0	INTEVT2	_	R	12-bit Exception Code

## **4.1.4** Exception Address Register (TEA)

TEA is assigned to address H'FFFFFFC and stores the virtual address for an exception occurrence when an exception related to memory accesses occurs. TEA can be modified using the software.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TEA	All 0	R/W	Virtual Address For Exception

## 4.2 Exception Handling Function

### 4.2.1 Exception Handling Flow

In exception handling, the contents of the program counter (PC) and status register (SR) are saved in the saved program counter (SPC) and saved status register (SSR), respectively, and execution of the exception handler is invoked from a vector address. The return from exception handler (RTE) instruction is issued by the exception handler routine on completion of the routine, restoring the contents of PC and SR to return to the processor state at the point of interruption and the address where the exception occurred.

A basic exception handling sequence consists of the following operations. If an exception occurs and the CPU accepts it, operations 1 to 8 are executed.

- 1. The contents of PC are saved in SPC.
- 2. The contents of SR are saved in SSR.
- www.D3.aS The block (BL) bit in SR is set to 1, masking any subsequent exceptions.
  - 4. The mode (MD) bit in SR is set to 1 to place the privileged mode.
  - 5. The register bank (RB) bit in SR is set to 1.
  - When an exception source is a general exception, an exception code identifying the exception
    event is written to EXPEVT. When an exception source is an interrupt, an exception code is
    written to INTEVT2.
  - 7. If a TRAPA instruction is executed, an 8-bit immediate data specified by the TRAPA instruction is set to TRA. For an exception related to memory accesses, the virtual address where the exception occurred is written to TEA.
  - Instruction execution jumps to the designed exception vector address to invoke the handler routine.

The above operations from 1 to 8 are executed in sequence. During these operations, no other exceptions may be accepted unless multiple exception acceptance is enabled.

In an exception handling routine for a general exception, the appropriate exception handling must be executed based on an exception source determined by the EXPEVT. In an interrupt exception handling routine, the appropriate exception handling must be executed based on an exception source determined by the INTEVT2. After the exception handling routine has been completed, program execution can be resumed by executing an RTE instruction. The RTE instruction causes the following operations to be executed.

- 1. The contents of the SSR are restored into the SR to return to the processing state in effect before the exception handling took place.
- 2. A delay slot instruction of the RTE instruction is executed.\*
- 3. Control is passed to the address stored in the SPC.

The above operations from 1 to 3 are executed in sequence. During these operations, no other exceptions may be accepted. By changing the SPC and SSR before executing the RTE instruction, a status different from that in effect before the exception handling can also be specified.

Note: \* For details on the CPU processing mode in which RTE delay slot instructions are executed, please refer to section 4.5, Usage Notes.

## 4.2.2 Exception Vector Addresses

A vector address for general exceptions is determined by adding a vector offset to a vector base address. The vector offset for general exceptions is H'00000100. The vector offset for interrupts is H'00000600. The vector base address is loaded into the vector base register (VBR) using the software. The vector base address should reside in the virtual address (P1 or P2).

### 4.2.3 Exception Codes

The exception codes are written to bits 11 to 0 of the EXPEVT register (for reset or general exceptions) or the INTEVT2 register (for interrupt requests) to identify each specific exception event. See section 8, Interrupt Controller (INTC), for details of the exception codes for interrupt requests. Table 4.1 lists exception codes for resets and general exceptions.

## 4.2.4 Exception Request and BL Bit (Multiple Exception Prevention)

The BL bit in SR is set to 1 when a reset or exception is accepted. While the BL bit is set to 1, acceptance of general exceptions is restricted as described below, making it possible to effectively prevent multiple exceptions from being accepted.

If the BL bit is set to 1, an interrupt request is not accepted and is retained. The interrupt request is accepted when the BL bit is cleared to 0. If the CPU is in power-down mode, an interrupt is accepted even if the BL bit is set to 1 and the CPU returns from power-down mode.

A DMA address error is not accepted and is retained if the BL bit is set to 1 and accepted when the BL bit is cleared to 0. User break requests generated while the BL bit is set are ignored and are not retained. Accordingly, user breaks are not accepted even if the BL bit is cleared to 0.

If a general exception other than a DMA address error or user break occurs while the BL bit is set to 1, the CPU enters a state similar to that in effect immediately after a reset, and passes control to the reset vector (H'A0000000) (multiple exception). In this case, unlike a normal reset, modules

other than the CPU are not initialized, the contents of EXPEVT, SPC, and SSR are undefined, and this status is not detected by an external device.

To enable acceptance of multiple exceptions, the contents of SPC and SSR must be saved while the BL bit is set to 1 after an exception has been accepted, and then the BL bit must be cleared to 0. Before restoring the SPC and SSR, the BL bit must be set to 1.

### 4.2.5 Exception Source Acceptance Timing and Priority

**Exception Request of Instruction Synchronous Type and Instruction Asynchronous Type:** 

Resets and interrupts are requested asynchronously regardless of the program flow. In general exceptions, a DMA address error and a user break under the specific condition are also requested asynchronously. The user cannot expect on which instruction an exception is requested. For general exceptions other than a DMA address error and a user break under a specific condition, each general exception corresponds to a specific instruction.

**Re-execution Type and Processing-completion Type Exceptions:** All exceptions are classified into two types: a re-execution type and a processing-completion type. If a re-execution type exception is accepted, the current instruction executed when the exception is accepted is terminated and the instruction address is saved to the SPC. After returning from the exception processing, program execution resumes from the instruction where the exception was accepted. In a processing-completion type exception, the current instruction executed when the exception is accepted is completed, the next instruction address is saved to the SPC, and then the exception processing is executed.

During a delayed branch instruction and delay slot, the following operations are executed. A reexecution type exception detected in a delay slot is accepted before executing the delayed branch
instruction. A processing-completion type exception detected in a delayed branch instruction or a
delay slot is accepted when the delayed branch instruction has been executed. In this case, the
acceptance of delayed branch instruction or a delay slot precedes the execution of the branch
destination instruction. In the above description, a delay slot indicates an instruction following an
unconditional delayed branch instruction or an instruction following a conditional delayed branch
instruction whose branch condition is satisfied. If a branch does not occur in a conditional delayed
branch, the normal processing is executed.

Acceptance Priority and Test Priority: Acceptance priorities are determined for all exception requests. The priority of resets, general exceptions, and interrupts are determined in this order: a reset is always accepted regardless of the CPU status. Interrupts are accepted only when resets or general exceptions are not requested.

If multiple general exceptions occur simultaneously in the same instruction, the priority is determined as follows.

- 1. A processing-completion type exception generated at the previous instruction\*
- 2. A user break before instruction execution (re-execution type)
- 3. An exception related to an instruction fetch (CPU address error)
- 4. An exception caused by an instruction decode (General illegal instruction exceptions and slot illegal instruction exceptions: re-execution type, unconditional trap: processing-completion type)
- 5. An exception related to data access (CPU address error)
- 6. Unconditional trap (processing-completion type)
- 7. A user break other than one before instruction execution (processing-completion type)
- 8. DMA address error (processing-completion type)

Note: \* If a processing-completion type exception is accepted at an instruction, exception processing starts before the next instruction is executed. This exception processing executed before an exception generated at the next instruction is detected.

Only one exception is accepted at a time. Accepting multiple exceptions sequentially results in all exception requests being processed.

**Table 4.1 Exception Event Vectors** 

	•						
Exception Type	Current Instruction	Exception Event	Priority*1	Exception Order	Process at BL=1	Excep-tion Code* <sup>5</sup>	Vector Offset
Reset	Aborted	Power-on reset	1	1	Reset	H'000	_
(Instruction asynchro- nous type)		Manual reset	1	2	Reset	H'020	_
General exception events	Re-executed	User break(before instruction execution)	2	0	Ignored	H'1E0	H'00000100
(Instruction synchro- nous type)		CPU address error (instruction access)  *4	2	1	Reset	H'0E0	H'00000100
		Illegal general instruction exception	2	2	Reset	H'180	H'00000100
DataSheet4U.		Illegal slot instruction exception	2	2	Reset	H'1A0	H'00000100
		CPU address error (data read/write)*4	2	3	Reset	H'0E0/ H'100	H'00000100
	Completed	Unconditional trap (TRAPA instruction)	2	4	Reset	H'160	H'00000100
		User breakpoint (After instruction execution, address)	2	5	Ignored	H'1E0	H'00000100
General exception events	Completed	User breakpoint (Data break, I-BUS break)	2	5	Ignored	H'1E0	H'00000100
(Instruction asynchronous type)		DMA address error	2	6	Retained	H'5C0	H'00000100
Interrupt (Instruction	Completed	Nonmaskable interrupt (NMI)	3* <sup>2</sup>	_	Retained	*³	H'00000600
asynchro- nous type)		External hardware interrupt (IRQ interrupt)	4*2		Retained	* <sup>3</sup>	H'00000600
		H-UDI interrupt	4*2	_	Retained	*³	H'00000600
		On-chip peripheral module interrupt	4*2	_	Retained	*³	H'00000600

- Notes: 1. Priorities are indicated from high to low, 1 being the highest and 4 the lowest. A reset has the highest priority. An interrupt is accepted only when general exceptions are not requested.
  - 2. For details on priorities in multiple interrupt sources, refer to section 8, Interrupt Controller (INTC).
  - 3. If an interrupt is accepted, the exception event register (EXPEVT) is not changed. The interrupt source code is specified in interrupt event register 2 (INTEVT2). For details, refer to section 8, Interrupt Controller (INTC).
  - 4. If one of these exceptions occurs in a specific part of the repeat loop, a specific code and vector offset are specified.
  - Exception codes H'040, H'060, H'080, H'0A0, H'0C0, H'0D0, H'120, H'140, and H'3E0 are reserved.

## **4.3** Individual Exception Operations

This section describes the conditions for specific exception handling, and the processor operations. Resets and general exceptions are explained in this section. For details of interrupts, see section 8, Interrupt Controller (INTC)

#### **4.3.1** Resets

#### Power-On Reset:

- Conditions
  - RESETP is low, power-on reset by WDT is requested, H-UDI reset
- Operations

Set EXPEVT to H'000, initialize VBR and SR, and branch to PC = H'A0000000.\* The VBR register is cleared to H'00000000 by the initialization. In the SR register, the bits MD, RB, and BL are set to 1, the DSP bit is cleared to 0, and interrupt mask bits (I3 to I0) are set to B'1111.

Initialize the CPU and on-chip peripheral modules. For details, refer to the register descriptions in the relevant sections.

Perform a reset by the RESETP pin low at power supply.

Note: \* After a power-on reset, though address is H'A0000000, if the BOOT\_E pin is asserted low, a branch is made to the ROM area for the boot function and the boot processing starts (see section 17, Boot Function).

For the details of the H UDI reset, see section 26, User Debugging Interface (H-UDI).

#### **Manual Reset:**

- Conditions
   Manual reset by WDT is request
- Operations

Set EXPEVT to H'020, initialize VBR and SR, and branch to PC = H'A0000000.\* The VBR register is cleared to H'00000000 by the initialization. In the SR register, the bits MD, RB, and BL are set to 1, the DSP bit is cleared to 0, and interrupt mask bits (I3 to I0) are set to B'1111. Initialize the CPU and on-chip peripheral modules. A register initialized by a power-on reset is different from that is initialized by a manual reset. For details, refer to the register descriptions in the relevant sections.

Note: \* After a manual reset, if the BOOT\_E pin is asserted low, a branch is made to the ROM area for the boot function and the boot processing starts as in the case of the power-on reset.

### 4.3.2 General Exceptions

#### CPU address error:

- Conditions
  - Instruction is fetched from odd address (4n + 1, 4n + 3)
  - Word data is accessed from addresses other than word boundaries (4n + 1, 4n + 3)
  - Longword is accessed from addresses other than longword boundaries (4n + 1, 4n + 2, 4n + 3)
  - The area ranging from H'80000000 to H'FFFFFFF in logical space is accessed in user mode.
- Types

Instruction synchronous, re-execution type

Save address

Instruction fetch: An instruction address to be fetched when an exception occurred www.DataSrData access: An instruction address where an exception occurs (a delayed branch instruction

address if an instruction is assigned to a delay slot)

Exception code

An exception occurred during read: H'0E0

An exception occurred during write: H'100

Remarks

The virtual address (32 bits) that caused the exception is set in TEA.

## Illegal general instruction exception:

- Conditions
  - When undefined code not in a delay slot is decodedDelayed branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S

Note: For details on undefined code, refer to section 2.6.2, Operation Code Map. When an undefined code other than H'FC00 to H'FFFF is decoded, operation cannot be guaranteed.

- When a privileged instruction not in a delay slot is decoded in user mode
   Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions.
- Types

Instruction synchronous, re-execution type

Save address

An instruction address where an exception occurs

- Exception code H'180
- Remarks
  None

### Illegal slot instruction:

- Conditions
  - When undefined code in a delay slot is decoded
     Delayed branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S
  - When a privileged instruction in a delay slot is decoded in user mode
     Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions.
  - When an instruction that rewrites PC in a delay slot is decoded
     Instructions that rewrite PC: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT, BF, BT/S, BF/S, TRAPA, LDC Rm, SR, LDC.L @Rm+, SR
- Types

Instruction synchronous, re-execution type

- Save address
  - A delayed branch instruction address
- Exception code
  - H'1A0
- Remarks

None

#### **Unconditional trap:**

- Conditions
  - TRAPA instruction executed
- Types

Instruction synchronous, processing-completion type

- Save address
  - An address of an instruction following TRAPA
- Exception code
  - H'160
- Remarks

The exception is a processing-completion type, so PC of the instruction after the TRAPA instruction is saved to SPC. The 8-bit immediate value in the TRAPA instruction is set in TRA[9:2].

www.DataSheet4U.com

Rev. 1.00, 02/04, page 166 of 804

#### User break point trap:

Conditions

When a break condition set in the user break controller is satisfied

Types

Break (L bus) before instruction execution: Instruction synchronous, re-execution type Operand break (L bus): Instruction synchronous, processing-completion type Data break (L bus): Instruction asynchronous, processing-completion type I bus break: Instruction asynchronous, processing-completion type

Save address

Re-execution type: An address of the instruction where a break occurs (a delayed branch instruction address if an instruction is assigned to a delay slot)

Completion type: An address of the instruction following the instruction where a break occurs (a delayed branch instruction destination address if an instruction is assigned to a delay slot)

• Exception code

www.DataSh**He1E0**com

Remarks

For details on user break controller, refer to section 25, User Break Controller (UBC).

#### DMA address error:

- Conditions
  - Word data accessed from addresses other than word boundaries (4n + 1, 4n + 3)
  - Longword accessed from addresses other than longword boundaries (4n + 1, 4n + 2, 4n + 3)
- Types

Instruction asynchronous, processing-completion type

· Save address

An address of the instruction following the instruction where a break occurs (a delayed branch instruction destination address if an instruction is assigned to a delay slot)

• Exception code

H'5C0

Remarks

An exception occurs when a DMA transfer is executed while an illegal instruction address described above is specified in the DMAC. Since the DMAC transfer is performed asynchronously with the CPU instruction operation, an exception is also requested asynchronously with the instruction execution. For details on DMAC, refer to section 10, Direct Memory Access Controller (DMAC).

Note: Address error does not occurred in the USB host since the hardware automatically recognizes the address and performs accessing data of enough bit hardsheet 4U.com

## 4.4 Exception Processing While DSP Extension Function is Valid

In DSP mode (the DSP bit of SR is set to 1), some exception processing acceptance conditions or exception processing may be changed.

### 4.4.1 Illegal Instruction Exception and Slot Illegal Instruction Exception

In the DSP mode, a DSP extension instruction can be executed. If a DSP extension instruction is executed when the DSP bit of SR is cleared to 0 (in a mode other than the DSP mode), an illegal instruction exception occurs.

In the DSP mode, STC and LDC instructions for the SR register can be executed even in user mode. (Note, however, that only the RC[11:0], DMX, DMY, and RF[1:0] bits in the DSP extension bits can be changed.)

#### 4.4.2 CPU Address Error

In the DSP mode, a part of the space P2 (Uxy area: H'A5000000 to H'A5FFFFFF) can be accessed in user mode and no CPU address error will occur even if the area is accessed.

## 4.4.3 Exception in Repeat Control Period

If an exception is requested or an exception is accepted during repeat control, the exception may not be accepted correctly or a program execution may not be returned correctly from exception processing that is different from the normal state. These restrictions may occur from repeat detection instruction to repeat end instruction while the repeat counter is 1 or more. In this section, this period is called the repeat control period.

The following shows program examples where the number of instructions in the repeat loop is 4 or more, 3, 2, and 1, respectively. In this section, a repeat detection instruction and its instruction address are described as RptDtct. The first, second, and third instructions following the repeat detection instruction are described as RptDtct1, RptDtct2, and RptDtct3. In addition, [A], [B], [C1], and [C2] in the following examples indicate instructions where a restriction occurs. Table 4.2 summarizes the instruction positions regarding a repeat loop and restriction types.

Table 4.2 Instruction Positions regarding a repeat loop and Restriction Types

Instruction Position	SPC*1	Illegal Instruction* <sup>2</sup>	Interrupt, Break*³	CPU Address Error* <sup>4</sup>
[A]				
[B]			Retained	-
[C1]		Added	Retained	Instruction/data
[C2]	Illegal	Added	Retained	Instruction/data

Notes: 1. A specific address is specified in the SPC if an exception occurs while SR.RC[11:0] ≥ 2.

- 2. Some of instructions are turned to be illegal instructions while SR.RC[11:0] ≥ 1.
- 3. An interrupt, break or DMA address error request is retained while SR.RC[11:0] ≥ 1.
- 4. A specific exception code is specified while SR.RC[11:0] ≥ 1.

### • Example 1: Repeat loop consisting of four instructions

```

**SPC Saved by an Exception in Repeat Control Period:** If an exception is accepted in the repeat control period while the repeat counter (RC[11:0]) in the SR register is two or greater, the program counter to be saved may not indicate the value to be returned correctly. To execute the repeat control after returning from an exception processing, the return address must indicate an instruction prior to a repeat detection instruction. Accordingly, if an exception is accepted in repeat control period, an exception other than re-execution type exception by a repeat detection instruction cannot return to the repeat control correctly.

Table 4.3 SPC Value when a Re-Execution Type Exception Occurs in Repeat Control

Instruction Where an	Number of Instructions in a Repeat Loop				
<b>Exception Occurs</b>	1	2	3	4 or Greater	
RptDtct	RptDtct	RptDtct	RptDtct	RptDtct	
RptDtct1	RptDtct1	RptDtct1	RptDtct1	RptDtct1	
RptDtct2		RptDtct1	RptDtct1	RS-4	
RptDtct3	_	_	RptDtct1	RS-2	

www.DaNôte:et4The following symbols are used here.

RptDtct: Repeat detection instruction address

RptDtct1: An instruction address one instruction following the repeat detection

instruction (In a repeat loop consisting of one to three instructions, RptDtct1 is

equal to RptStart.)

RptDtct2: An instruction address two instruction following the repeat detection

instruction

RptDtct3: An instruction address three instruction following the repeat detection

instruction

RS: Repeat start instruction address

If a re-execution type exception is accepted at an instruction in the hatched areas above, a return address to be saved in the SPC is incorrect. If SR.RC[11:0] is 1 or 0, a correct return address is saved in the SPC.

**Illegal Instruction Exception in Repeat Control Period:** If one of the following instructions is executed at the address following RptDtct1, a general illegal instruction exception occurs. For details on an address to be saved in the SPC, refer to section 4.4.3, Exception in Repeat Control Period.

- Branch instructions
   BRA, BSR, BT, BF, BT/S, BF/S, BSRF, RTS, BRAF, RTE, JSR, JMP, TRAPA
- Repeat control instructions SETRC, LDRS, LDRE
- Load instructions for SR, RS, and RE
   LDC Rn,SR, LDC @Rn+,SR, LDC Rn,RE, LDC @Rn+,RE, LDC Rn,RS, LDC @Rn+, Rs

Note: In a repeat loop consisting of one to three instructions, some restrictions apply to repeat detection instructions and all the remaining instructions. In a repeat loop consisting of four or more instructions, restrictions apply to only the three instructions that include a repeat end instruction.

An Exception Retained in Repeat Control Period: In the repeat control period, an interrupt or some exception will be retained to prevent an exception acceptance at an instruction where returning from the exception cannot be performed correctly. For details, refer to repeat loop program examples (1) to (4). In the examples, exceptions generated at instructions indicated as [B], and [C] ([C1] or [C2]) the following processing is executed.

• Interrupt, DMA address error

An exception request is not accepted and retained at instructions [B] and [C]. If an instruction indicates as [A] is executed the next time, an exception request is accepted. As shown in examples (1) to (4), any interrupt or DMA address error cannot be accepted in a repeat loop consisting of four instructions or less.

Note: An interrupt request or a DMA address error exception request is retained in the interrupt controller (INTC) and the direct memory access controller (DMAC) until the CPU can accept a request.

• User break before instruction execution

A user break before instruction execution is accepted at instruction [B], and an address of instruction [B] is saved in the SPC. This exception cannot be accepted at instruction [C] but the exception request is retained until an instruction [A] or [B] is executed the next time. Then, the exception request is accepted before an instruction [A] or [B] is executed. In this case, an address of instruction [A] or [B] is saved in the SPC.

RENESAS

User break after instruction execution

A user break after instruction execution cannot be accepted at instructions [B] and [C] but the exception request is retained until an instruction [A] or [B] is executed the next time. Then, the exception request is accepted before an instruction [A] or [B] is executed. In this case, an address of instruction [A] or [B] is saved in the SPC.

Table 4.4 Restrictions of Exception Acceptance in the Repeat Loop

Exception Type	Instruction [B]	Instruction [C]
Interrupt	Not accepted	Not accepted
DMA address error	Not accepted	Not accepted
User break before instruction execution	Accepted	Not accepted
User break after instruction execution	Not accepted	Not accepted

**CPU Address Error in Repeat Control Period:** If a CPU address error occurs in the repeat control period, the exception is accepted but an exception code (H'070) indicating the repeat loop period is specified in the EXPEVT. If a CPU address error occurs in instructions following a repeat detection instruction to repeat end instruction, an exception code for instruction access or data access is specified in the EXPEVT.

The SPC is saved according to the description in section 4.4.3, SPC Saved by an Exception in Repeat Control Period.

After the CPU address error exception processing, the repeat control cannot be returned correctly. To execute a repeat loop correctly, care must be taken not to generate a CPU address error in the repeat control period.

Note: In a repeat loop consisting of one to three instructions, some restrictions apply to repeat detection instructions and all the remaining instructions. In a repeat loop consisting of four or more instructions, restrictions apply to only the three instructions that include a repeat end instruction. The restriction occurs when  $SR.RC[11:0] \ge 1$ .

Table 4.5 Instruction Where a Specific Exception Occurs When a Memory Access Exception Occurs in Repeat Control (SR.RC[11:0]  $\geq$  1)

instruction

An instruction address three instruction following the repeat detection RptDtct3:

instruction

## 4.5 Usage Notes

- An instruction assigned at a delay slot of the RTE instruction is executed after the contents of
  the SSR is restored into the SR. An acceptance of an exception related to instruction access is
  determined according to the SR before restore. An acceptance of other exceptions is
  determined by the SR after restore, processing mode, and BL bit value. A processingcompletion type exception is accepted before an instruction at the RTE branch destination
  address is executed. However, note that the correct operation cannot be guaranteed if a reexecution type exception occurs.
- 2. In an instruction assigned at a delay slot of the RTE instruction, a user break cannot be accepted.
- 3. If the MD and BL bits of the SR register are changed by the LDC instruction, an exception is accepted according to the changed SR value from the next instruction.\* A processing-completion type exception is accepted after the next instruction is executed. An interrupt and DMA address error in processing-completion type exceptions are accepted before the next instruction is executed.

ww.DataSheet4U.com

Note: \* If an LDC instruction is executed for the SR, the following instructions are re-fetched and an instruction fetch exception is accepted according to the modified SR value.

## Section 5 Cache

### 5.1 Features

Capacity: 16 kbytes

• Structure: Instructions/data mixed, 4-way set associative

• Locking: Way 2 and way 3 are lockable

• Line size: 16 bytes

• Number of entries: 256 entries/way

• Write system: Write-back/write-through is selectable for spaces P0, P1, P3, and U0 individually.

Group 1 (P0, P3, and U0 areas)

Group 2 (P1 area)

• Replacement method: Least-recently used (LRU) algorithm

ww.DataSheet4U.com

#### **5.1.1** Cache Structure

The cache mixes instructions and data and uses a 4-way set associative system. It is composed of four ways (banks), and each of which is divided into an address section and a data section. Each of the address and data sections is divided into 256 entries. The entry data is called a line. Each line consists of 16 bytes (4 bytes  $\times$  4). The data capacity per way is 4 kbytes (16 bytes  $\times$  256 entries) in the cache as a whole (4 ways). The cache capacity is 16 kbytes as a whole. Figure 5.1 shows the cache structure.

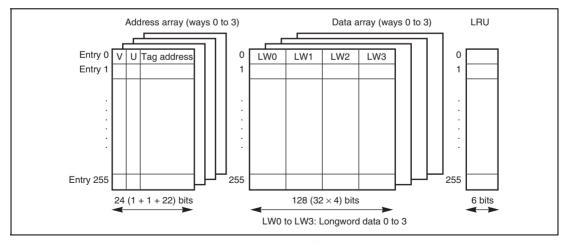

Figure 5.1 Cache Structure

**Address Array:** The V bit indicates whether the entry data is valid. When the V bit is 1, data is valid; when 0, data is not valid. The U bit indicates whether the entry has been written to in writeback mode. When the U bit is 1, the entry has been written to; when 0, it has not. The tag address holds the physical address used in the external memory access. It is composed of 22 bits (address bits 31 to 10 for memory access) used for comparison during cache searches.

In this LSI, the top three of 32 physical address bits are used as shadow bits (see section 9, Bus State Controller (BSC)), and therefore the top three bits of the tag address are cleared to 0.

The V and U bits are initialized to 0 by a power-on reset, but are not initialized by a manual reset. The tag address is not initialized by either a power-on or manual reset.

**Data Array:** Holds a 16-byte instruction or data. Entries are registered in the cache in line units (16 bytes). The data array is not initialized by a power-on or manual reset.

**LRU:** With the 4-way set associative system, up to four instructions or data with the same entry address can be registered in the cache. When an entry is registered, LRU shows which of the four ways it is recorded in. There are six LRU bits, controlled by hardware. A least-recently-used (LRU) algorithm is used to select the way.

Six LRU bits indicate the way to be replaced, when a cache miss occurs. Table 5.1 shows the relationship between the LRU bits and the way to be replaced when the cache locking mechanism is disabled. (For the relationship when the cache locking mechanism is enabled, refer to section 5.2.2, Cache Control Register 2.) If a bit pattern other than those listed in table 5.1 is set in the LRU bits by software, the cache will not function correctly. When modifying the LRU bits by software, set one of the patterns listed in table 5.1.

The LRU bits are initialized to B'000000 by a power-on reset, but are not initialized by a manual reset.

 Table 5.1
 LRU and Way Replacement (when Cache Locking Mechanism is Disabled)

LRU (Bits 5 to 0)	Way to be Replaced
000000, 000100, 010100, 100000, 110000, 110100	3
000001, 000011, 001011, 100001, 101001, 101011	2
000110, 000111, 001111, 010110, 011110, 011111	1
111000, 111001, 111011, 111100, 111110, 111111	0

# 5.2 Register Descriptions

The cache has the following registers. For details on register addresses and register access size, refer to section 27, List of Registers.

- Cache control register 1 (CCR1)
- Cache control register 2 (CCR2)

## 5.2.1 Cache Control Register 1 (CCR1)

The cache is enabled or disabled using the CE bit in CCR1. CCR1 also has a CF bit (which invalidates all cache entries), and WT and CB bits (which select either write-through mode or write-back mode). Programs that change the contents of the CCR1 register should be placed in address space that is not cached.

	Bit	Bit Name	Initial Value	R/W	Description
Dat	aSheet4U		value	IX/VV	Description
	31 to 4	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
•	3	CF	0	R/W	Cache Flush
					Writing 1 flushes all cache entries (clears the V, U, and LRU bits of all cache entries to 0). This bit is always read as 0. Write-back to external memory is not performed when the cache is flushed.
	2	CB	0	R/W	Write-Back
					Indicates the cache's operating mode for space P1.
					0: Write-through mode 1: Write-back mode
-	1	WT	0	R/W	Write-Through
					Indicates the cache's operating mode for spaces P0, U0, and P3.
					0: Write-back mode 1: Write-through mode
•	0	CE	0	R/W	Cache Enable
					Indicates whether the cache function is used.
					0: The cache function is not used. 1: The cache function is used.

# 5.2.2 Cache Control Register 2 (CCR2)

The CCR2 register controls the cache locking mechanism in DSP mode only. The CPU enters DSP mode when the DSP bit (bit 12) in the status register (SR) is set to 1. The cache locking mechanism is disabled in non-DSP mode (DSP bit = 0).

When a prefetch instruction (PREF@Rn) is issued in DSP mode and a cache miss occurs, the line of data pointed to by Rn will be loaded into the cache, according to the setting of bits 9 and 8 (W3LOAD, W3LOCK) and bits 1 and 0 (W2LOAD, W2LOCK in CCR2).

Table 5.2 shows the relationship between the settings of bits and the way that is to be replaced when the cache is missed by a prefetch instruction.

On the other hand, when the cache is hit by a prefetch instruction, new data is not loaded into the cache and the valid entry is held. For example, a prefetch instruction is issued while bits W3LOAD and W3LOCK are set to 1 and the line of data to which Rn points is already in way 0, the cache is hit and new data is not loaded into way 3.

In DSP mode, bits W3LOCK and W2LOCK restrict the way that is to be replaced, when instructions other than the prefetch instruction are issued. Table 5.3 shows the relationship between the settings of bits in CCR2 and the way that is to be replaced when the cache is missed by instructions other than the prefetch instruction.

Programs that change the contents of the CCR2 register should be placed in address space that is not cached.

RENESAS

			Initial		
Bit	t	Bit Name	Value	R/W	Description
31	to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.	
9		W3LOAD	0	R/W	Way 3 Load (W3LOAD)
8		W3LOCK	0	R/W	Way 3 Lock (W3LOCK)
				When the cache is missed by a prefetch instruction while in DSP mode and when bits W3LOAD and W3LOCK in CCR2 are set to 1, the data is always loaded into way 3. Under any other condition, the prefetched data is loaded into the way to which LRU points.	
7 t	o 2	_	All 0	R	Reserved
	heet4U.co				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
1		W2LOAD	0	R/W	Way 2 Load (W2LOAD)
0		W2LOCK	0	R/W	Way 2 Lock (W2LOCK)
					When the cache is missed by a prefetch instruction while in DSP mode and when bits W2LOAD and W2LOCK in CCR2 are set to 1, the data is always loaded into way 2. Under any other condition, the prefetched data is loaded into the way to which LRU points.

Note: W2LOAD and W3LOAD should not be set to 1 at the same time.

Table 5.2 Way Replacement when a PREF Instruction Misses the Cache

DSP Bit	W3LOAD	W3LOCK	W2LOAD	W2LOCK	Way to be Replaced
0	*	*	*	*	Determined by LRU (table 5.1)
1	*	0	*	0	Determined by LRU (table 5.1)
1	*	0	0	1	Determined by LRU (table 5.4)
1	0	1	*	0	Determined by LRU (table 5.5)

# 5.3 Operation

#### 5.3.1 Searching the Cache

If the cache is enabled (the CE bit in CCR1 = 1), whenever instructions or data in spaces P0, P1, P3, and U0 are accessed the cache will be searched to see if the desired instruction or data is in the cache. Figure 5.2 illustrates the method by which the cache is searched. The cache is a physical cache and holds physical addresses in its address section.

Entries are selected using bits 11 to 4 of the address (virtual) of the access to memory and the tag address of that entry is read. The virtual address (bits 31 to 10) of the access to memory and the physical address (tag address) read from the address array are compared. The address comparison uses all four ways. When the comparison shows a match and the selected entry is valid (V = 1), a cache hit occurs. When the comparison does not show a match or the selected entry is not valid (V = 0), a cache miss occurs. Figure 5.2 shows a hit on way 1.

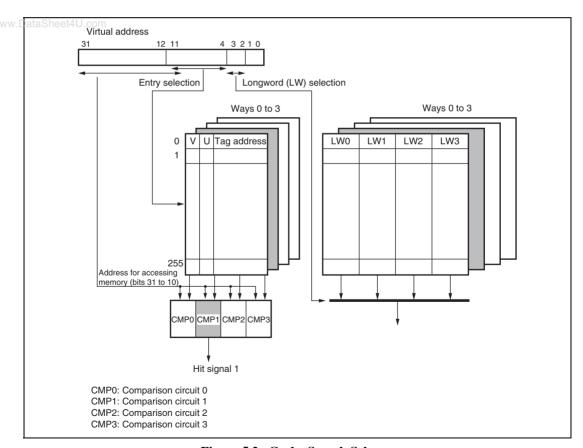

Figure 5.2 Cache Search Scheme

#### 5.3.2 Read Access

**Read Hit:** In a read access, instructions and data are transferred from the cache to the CPU. The LRU is updated to indicate that the hit way is the most recently hit way.

**Read Miss:** An external bus cycle starts and the entry is updated. The way to be replaced is shown in table 5.3. Entries are updated in 16-byte units. When the desired instruction or data that caused the miss is loaded from external memory to the cache, the instruction or data is transferred to the CPU in parallel with being loaded to the cache. When it is loaded to the cache, the U bit is cleared to 0 and the V bit is set to 1 to indicate that the hit way is the most recently hit way. When the U bit for the entry which is to be replaced by entry updating in write-back mode is 1, the cache-update cycle starts after the entry is transferred to the write-back buffer. After the cache completes its update cycle, the write-back buffer writes the entry back to the memory. Transfer is in 16-byte units.

# 5.3.3 Prefetch Operation

**Prefetch Hit:** The LRU is updated to indicate that the hit way is the most recently hit way. The other contents of the cache are not changed. Instructions and data are not transferred from the cache to the CPU.

**Prefetch Miss:** Instructions and data are not transferred from the cache to the CPU. The way that is to be replaced is shown in table 5.2. The other operations are the same as those for a read miss.

#### 5.3.4 Write Access

**Write Hit:** In a write access in write-back mode, the data is written to the cache and no external memory write cycle is issued. The U bit of the entry that has been written to is set to 1, and the LRU is updated to indicate that the hit way is the most recently hit way. In write-through mode, the data is written to the cache and an external memory write cycle is issued. The U bit of the entry that has been written to is not updated, and the LRU is updated to indicate that the hit way is the most recently hit way.

**Write Miss:** In write-back mode, an external cycle starts when a write miss occurs, and the entry is updated. The way to be replaced is shown in table 5.3. When the U bit of the entry which is to be replaced by entry updating is 1, the cache-update cycle starts after the entry has been transferred to the write-back buffer. Data is written to the cache and the U bit and the V bit are set to 1. The LRU is updated to indicate that the replaced way is the most recently updated way. After the cache has completed its update cycle, the write-back buffer writes the entry back to the memory. Transfer is in 16-byte units. In write-through mode, no write to cache occurs in a write miss; the write is only to the external memory.

#### 5.3.5 Write-Back Buffer

When the U bit of the entry to be replaced in write-back mode is 1, the entry must be written back to the external memory. To increase performance, the entry to be replaced is first transferred to the write-back buffer and fetching of new entries to the cache takes priority over writing back to the external memory. After the fetching of new entries to the cache completes, the write-back buffer writes the entry back to the external memory. During the write-back cycles, the cache can be accessed. The write-back buffer can hold one line of cache data (16 bytes) and its physical address. Figure 5.3 shows the configuration of the write-back buffer.

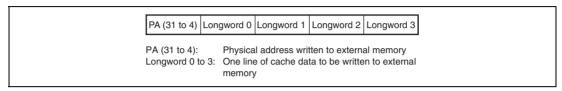

Figure 5.3 Write-Back Buffer Configuration

DataSheet4U.com

#### 5.3.6 Coherency of Cache and External Memory

Use software to ensure coherency between the cache and the external memory. When memory shared by this LSI and another device is placed in an address space to which caching applies, use the memory-mapped cache to make the data invalid and written back, as required. Memory that is shared by this LSI's CPU and DMAC should also be handled in this way.

# 5.4 Memory-Mapped Cache

To allow software management of the cache, cache contents can be read and written by means of MOV instructions in privileged mode. The cache is mapped onto the P4 area in virtual address space. The address array is mapped onto addresses H'F0000000 to H'F0FFFFF, and the data array onto addresses H'F1000000 to H'F1FFFFFF. Only longword can be used as the access size for the address array and data array, and instruction fetches cannot be performed.

#### 5.4.1 Address Array

The address array is mapped onto H'F0000000 to H'F0FFFFFF. To access an address array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the tag address, V bit, U bit, and LRU bits to be written to the address array.

In the address field, specify the entry address for selecting the entry, W for selecting the way, A for enabling or disabling the associative operation, and H'F0 for indicating address array access. As for W, B'00 indicates way 0, B'01 indicates way 1, B'10 indicates way 2, and B'11 indicates way 3.

In the data field, specify the tag address, LRU bits, U bit, and V bit. Figure 5.4 shows the address and data formats. Os should be specified in upper three bits (bits 31 to 29) of the tag address. The following three operations are available in the address array.

**Address-Array Read:** Read the tag address, LRU bits, U bit, and V bit for the entry that corresponds to the entry address and way specified by the address field of the read instruction. In reading, the associative operation is not performed, regardless of whether the associative bit (A bit) specified in the address is 1 or 0.

**Address-Array Write (non-Associative Operation):** Write the tag address, LRU bits, U bit, and V bit, specified by the data field of the write instruction, to the entry that corresponds to the entry address and way as specified by the address field of the write instruction. Ensure that the associative bit (A bit) in the address field is set to 0. When writing to a cache line for which the U bit = 1 and the V bit = 1, write the contents of the cache line back to memory, then write the tag address, LRU bits, U bit, and V bit specified by the data field of the write instruction. When 0 is written to the V bit, 0 must also be written to the U bit for that entry.

**Address-Array Write (Associative Operation):** When writing with the associative bit (A bit) of the address = 1, the addresses in the four ways for the entry specified by the address field of the write instruction are compared with the tag address that is specified by the data field of the write instruction. Write the U bit and the V bit specified by the data field of the write instruction to the entry of the way that has a hit. However, the tag address and LRU bits remain unchanged. When there is no way that receives a hit, nothing is written and there is no operation. This function is

www.DataSheet4U.com

Rev. 1.00, 02/04, page 186 of 804

used to invalidate a specific entry in the cache. When the U bit of the entry that has received a hit is 1 at this point, writing back should be performed. However, when 0 is written to the V bit, 0 must also be written to the U bit of that entry.

# 5.4.2 Data Array

The data array is mapped onto H'F1000000 to H'F1FFFFF. To access a data array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the longword data to be written to the data array.

In the address field, specify the entry address for selecting the entry, L for indicating the longword position within the (16-byte) line, W for selecting the way, and H'F1 for indicating data array access. As for L, B'00 indicates longword 0, B'01 indicates longword 1, B'10 indicates longword 2, and B'11 indicates longword 3. As for W, B'00 indicates way 0, B'01 indicates way 1, B'10 indicates way 2, and B'11 indicates way 3).

Since access size of the data array is fixed at longword, bits 1 and 0 of the address field should be set to B'00.

Figure 5.4 shows the address and data formats.

The following two operations on the data array are available. The information in the address array is not affected by these operations.

**Data-Array Read:** Read the data specified by L of the address filed, from the entry that corresponds to the entry address and the way that is specified by the address filed.

**Data-Array Write:** Write the longword data specified by the data filed, to the position specified by L of the address field, in the entry that corresponds to the entry address and the way specified by the address field.

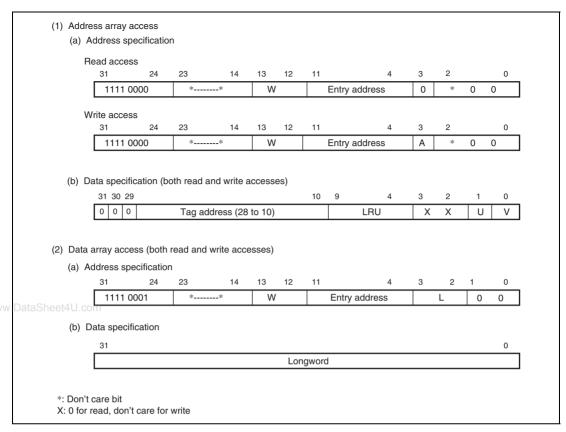

Figure 5.4 Specifying Address and Data for Memory-Mapped Cache Access

#### **5.4.3** Usage Examples

**Invalidating Specific Entries:** Specific cache entries can be invalidated by writing 0 to the entry's V bit in the memory-mapped cache access. When the A bit is 1, the tag address specified by the write data is compared to the tag address within the cache selected by the entry address, and a match is found, the entry is written back if the entry's U bit is 1 and the V bit and U bit specified by the write data are written. If no match is found, there is no operation. In the example shown below, R0 specifies the write data and R1 specifies the address.

```
; R0=H'01100010; specification of data for address array access, tag address=B'0 0001 0001 0000 0000 00, LRU = B'00 0001, U=0, V=0 ; R1=H'F0000088; specification of address to be accessed in address array access, way = B'00, entry address=B'00001000, A=1 ; MOV.L~R0,@R1
```

**Reading the Data of a Specific Entry:** To read the data field of a specific entry is enabled by the memory-mapped cache access. The longword indicated in the data field of the data array in figure 5.4 is read into the register. In the example shown below, R0 specifies the address and R1 shows what is read.

```
; R0=H'F100 004C; specification of address for data array access, way=B'00, entry address=B'00000100, L=B'11; MOV.L @R0,R1; Longword 3 is read.
```

# Section 6 X/Y Memory

This LSI has on-chip 8 kbytes of X-memory and Y-memory that can be used to store instructions or data.

#### 6.1 Features

#### Page

There are four pages. The X memory is divided into two pages (pages 0 and 1) and the Y memory is divided into two pages (pages 0 and 1).

# Memory map

The X/Y memory is located in the virtual address space, physical address space. In the virtual address space, this memory is located in the addresses in P2/Uxy that are shown in table 6.1. These addresses are included in space P2 (when SR.MD = 1) or Uxy (when SR.MD = 0 and SR.DSP = 1) according to the CPU operating mode.

DataSheet4U.com

Table 6.1 X/Y Memory Virtual Addresses

Page	Memory Size (16 kbytes in Total Four Pages)
Page 0 of X memory	H'A5007000 to H'A5007FFF
Page 1 of X memory	H'A5008000 to H'A5008FFF
Page 0 of Y memory	H'A5017000 to H'A5017FFF
Page 1 of Y memory	H'A5018000 to H'A5018FFF

On the other hand, virtual addresses shown in table 6.1 are located in a part of area 1 in the physical address space. When this memory is accessed from the physical address space, addresses in which the upper three bits are 0 in addresses shown in table 6.1 are used.

#### Ports

Each page has three independent read/write ports and is connected to each bus. The X memory is connected to the I bus, X bus, and L bus. The Y memory is connected to the I bus, Y bus, and L bus. The L bus, X bus, and Y bus are used when this memory is accessed from the virtual address space. The I bus is used when this memory is accessed from the physical address space.

#### Priority order

In the event of simultaneous accesses to the same page from different buses, the accesses are processed according to the priority order. The priority order is: I bus > X bus > L bus in the X memory and I bus > Y bus > L bus in the Y memory.

# 6.2 Operation

#### 6.2.1 Access from CPU

The 8/16/32-bit access by the CPU can be performed via the L bus or I bus. Methods for accessing by the CPU are via the L bus from the virtual addresses, and via the I bus from the physical addresses. As long as a conflict on the page does not occur, access via the L bus is performed in one cycle. Several cycles are necessary for accessing via the I bus. According to the CPU operating mode, access from the CPU is as follows:

Privileged mode and privileged DSP mode (SR. MD = 1): The X/Y memory can be accessed by the CPU from spaces P0 and P2.

User DSP mode (SR.MD = 0 and SR.DSP = 1): The X/Y memory can be accessed by the CPU from spaces U0 and Uxy.

User mode (SR.MD = 0 and SR.DSP = 0): The X/Y memory can be accessed by the CPU from www.Dspace U0.

#### 6.2.2 Access from DSP

The 16/32-bit access by the DSP can be performed via the L bus or I bus. A 16-bit access by the DSP can be performed via the X and Y buses. Methods for accessing from the DSP differ according to instructions.

With a X data transfer instruction and a Y data transfer instruction, the X/Y memory is always accessed via the X bus or Y bus. As long as a conflict on the page does not occur, access via the X bus or Y bus is performed in one cycle. The X memory access via the X bus and the Y memory access via the Y bus can be performed simultaneously.

In the case of a single data transfer instruction, methods for accessing from the DSP are directly via the L bus from the virtual addresses, and via the I bus from the physical addresses. As long as a conflict on the page does not occur, access via the L bus is performed in one cycle. Several cycles are necessary for accessing via the I bus. According to the CPU operating mode, access from the CPU is as follows:

**Privileged DSP mode (SR. MD = 1 and SR.DSP = 1):** The X/Y memory can be accessed by the DSP from spaces P0 and P2.

User DSP mode (SR.MD = 0 and SR.DSP = 1): The X/Y memory can be accessed by the DSP from spaces U0 and Uxy.

#### 6.2.3 Access from I Bus Master Module

The X/Y memory is always accessed by I bus master modules such as the DMAC and USBH via the I bus, which is a physical address bus. The 8/16/32-bit access is performed by the DMAC and 8/32-bit access is performed by the USBH. When accessing other than the P4 area (A31 to A29 = B'111), three most significant bits of the address are internally set to B'000 even if the logic addresses are specified other than P4 area. Therefore, access is performed through I bus.

# 6.3 Usage Notes

#### **6.3.1** Page Conflict

In the event of simultaneous accesses to the same page from different buses, the conflict on the pages occurs. Although each access is completed correctly, this kind of conflict tends to lower X/Y memory accessibility. Therefore it is advisable to provide software measures to prevent such conflict as far as possible. For example, conflict will not arise if different memory or different www.Dapages are accessed by each bus.

#### 6.3.2 Bus Conflict

The I bus is shared by several bus master modules. When the X/Y memory is accessed via the I bus, a conflict between the other I-bus master modules may occur on the I bus. This kind of conflict tends to lower X/Y memory accessibility. Therefore it is advisable to provide software measures to prevent such conflict as far as possible. For example, by accessing the X/Y memory by the CPU not via the I bus but from space P2 or Uxy via the L bus, conflict on the I bus can be prevented.

# 6.3.3 Cache Settings

When the X/Y memory is accessed via the I bus using the cache from the CPU and DSP, correct operation cannot be guaranteed. If the X/Y memory is accessed while the cache is enabled (CCR1.CE = 1), it is advisable to access the X/Y memory via the L bus from space P2 or Uxy. In a program that requires high performance, it is advisable to access the X/Y memory from space P2 or Uxy.

The relationship described above is summarized in table 6.2.

#### **Table 6.2** Cache Settings

0 - 11!
Setting

# Address Space and Access Enabled or Disabled

CCR1.CE	P0, U0	P2, Uxy
0	В	A
1	X	A

Note: A: Enabled (recommended)

B: Enabled

X: Disabled

# 6.3.4 Sleep Mode

The XYMCLKC bit of memory clock control register (MCCR) should be set to 1 when I bus master module such as DMAC accesses this memory in sleep mode.

There is the following restrictions when the X/Ymemory is accessed in the processing the exception handling and interrupt while this function is used.

- 1. The program of the exception handling and the interrupt processing should not be placed in the X/Y memory and U memory.
- 2. Eight NOP instructions should be added to the head of the exception handling and the interrupt processing program.
- 3. When the SLEEP instruction is executed, 16 instructions which include above-mentioned eight NOP instructions for the head of the exception handling and the interrupt processing should be placed outside of cache (Miss hit or non-cacheable area (P2)).

# • Example 1

Take out outside cache by using the address-array write (associative operation). (Refer to section 5.4, Memory Mapped Cache in section 5, Cache and Invalidating Specific Entries in section 5.4.3, Usage Examples.)

# • Example 2

The value of vector base register (VBR) is changed to non-cacheable area (P2) before the SLEEP instruction is executed. In this case, execute the SLEEP instruction after confirming the written VBR value (the branch instruction for the flag confirmation is used). After SLEEP ends, the VBR should be restored with the previous value.

# Section 7 U Memory

This LSI has on-chip 128-kbyte U memory which can be used to store instructions or data.

#### 7.1 Features

• Page

There are two pages (pages 0 and 1).

Memory map

The U memory is located in both the virtual address space and physical address space. In the virtual address space, this memory is located in the addresses in P2/Uxy that are shown in table 7.1. These addresses are included in space P2 (when SR.MD = 1) or Uxy (when SR.MD = 0 and SR.DSP = 1) according to the CPU operating mode.

# Table 7.1 U Memory Virtual Addresses

Page 14U.com	Memory Size (128 kbytes in Total Two Pages)			
Page 0 of U memory	H'A55F0000 to H'A55FFFFF			
Page 1 of U memory	H'A5600000 to H'A560FFF			

On the other hand, virtual addresses shown in table 7.1 are located in a part of area 1 in the physical address space. When this memory is accessed from the physical address space, addresses in which the upper three bits are 0 in addresses shown in table 7.1 are used.

#### Ports

Each page has two independent read/write ports and is connected to the I bus or L bus. The L bus is used when this memory is accessed from the virtual address space. The I bus is used when this memory is accessed from the physical address space.

# · Priority order

In the event of simultaneous accesses to the same page from different buses, the accesses are processed according to the priority order. The priority order is: I bus > L bus.

# 7.2 Operation

#### 7.2.1 Access from CPU

The 8/16/32-bit access by the CPU can be performed via the L bus or I bus. Methods for accessing by the CPU are directly via the L bus from the virtual addresses, and via the I bus from the physical addresses. As long as a conflict on the page does not occur, access via the L bus is performed in one cycle. Several cycles are necessary for accessing via the I bus. According to the CPU operating mode, access from the CPU is as follows:

**Privileged mode and privileged DSP mode (SR. MD = 1):** The U memory can be accessed by the CPU from spaces P0 and P2.

User DSP mode (SR.MD = 0 and SR.DSP = 1): The U memory can be accessed by the CPU from spaces U0 and Uxy.

User mode (SR.MD = 0 and SR.DSP = 0): The U memory can be accessed by the CPU from space U0.

#### 7.2.2 Access from DSP

The U memory can be accessed from the DSP only by a single data transfer instruction. The 16/32 -bit access by the DSP can be performed via the L bus or I bus. The access cannot be performed by an X data transfer instruction and a Y data transfer instruction.

Methods for accessing from the DSP are via the L bus from the virtual addresses, and via the I bus from the physical addresses. As long as a conflict on the page does not occur, access via the L bus is performed in one cycle. Several cycles are necessary for accessing via the I bus. According to the CPU operating mode, access from the CPU is as follows:

**Privileged DSP mode (SR. MD = 1 and SR.DSP = 1):** The U memory can be accessed by the DSP from spaces P0 and P2.

User DSP mode (SR.MD = 0 and SR.DSP = 1): The U memory can be accessed by the DSP from spaces U0 and Uxy.

#### 7.2.3 Access from I Bus Master Module

The U memory is always accessed by I bus master modules such as the DMAC and USBH via the I bus, which is a physical address bus. The 8/16/32-bit access can be performed by the DMAC and the 8/32-bit access can be performed by the USBH. When accessing other than the P4 area (A31 to A29 = B'111), three most significant bits of the address are internally set to B'000 even if the logic addresses are specified other than P4 area. Therefore, access is performed through I bus.

Rev. 1.00, 02/04, page 196 of 804

# 7.3 Usage Notes

#### 7.3.1 Page Conflict

In the event of simultaneous accesses to the same page from different buses, the conflict on the pages occurs. Although each access is completed correctly, this kind of conflict tends to lower U memory accessibility. Therefore it is advisable to provide software measures to prevent such conflict as far as possible. For example, conflict will not arise if different memory or different pages are accessed by each bus.

#### 7.3.2 Bus Conflict

The I bus is shared by several bus master modules. When the U memory is accessed via the I bus, a conflict between the other I-bus master modules may occur on the I bus. This kind of conflict tends to lower U memory accessibility. Therefore it is advisable to provide software measures to prevent such conflict as far as possible. For example, by accessing the U memory by the CPU not www.Davia the I bus but from space P2 or Uxy via the L bus, conflict on the I bus can be prevented.

## 7.3.3 Cache Settings

When the U memory is accessed via the I bus using the cache from the CPU and DSP, correct operation cannot be guaranteed. If the U memory is accessed while the cache is enabled (CCR1.CR = 1), it is advisable to access the U memory via the L bus from space P2 or Uxy. In a program that requires high performance, it is advisable to access the U memory from space P2 or Uxy.

The relationship described above is summarized in table 7.2.

**Table 7.2** Cache Settings

C-44:-- --

Setting	Address Space and Access Enabled of Disabled		
CCR1.CE	P0, U0	P2, Uxy	
0	В	A	
1	X	A	

Note: A: Enabled (recommended)

B: Enabled X: Disabled

## 7.3.4 sleep mode

The UMCLKC bit of memory clock control register (MCCR) should be set to 1 when I bus master module such as DMAC accesses this memory in sleep mode.

There is the following restrictions when the U memory is accessed in the processing the exception handling and interrupt while this function is used.

- 1. The program of the exception handling and the interrupt processing should not be placed in the U memory and X/Y memory.
- 2. Eight NOP instructions should be added to the head of the exception handling and the interrupt processing program.
- 3. When the SLEEP instruction is executed, 16 instructions which include above-mentioned eight NOP instructions for the head of the exception handling and the interrupt processing should be placed outside of cache (Miss hit or non-cacheable area (P2)).

# Example 1

Take out outside cache by using the address-array write (associative operation). (Refer to section 5.4, Memory Mapped Cache in section 5, Cache and Invalidating Specific Entries in section 5.4.3, Usage Examples.)

• Example 2

The value of vector base register (VBR) is changed to non-cacheable area (P2) before the SLEEP instruction is executed. In this case, execute the SLEEP instruction after confirming the written VBR value (the branch instruction for the flag confirmation is used). After SLEEP ends, the VBR should be restored with the previous value.

# Section 8 Interrupt Controller (INTC)

The interrupt controller (INTC) ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The INTC registers set the order of priority of each interrupt, allowing the user to process interrupt requests according to the user-set priority.

#### 8.1 Features

- 16 levels of interrupt priority can be set
  - By setting the interrupt priority registers, the priorities of on-chip peripheral module and IRQ interrupts can be selected from 16 levels for individual request sources.
- NMI noise canceler function
  - An NMI input-level bit indicates the NMI pin state. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as a noise canceler.
- www.paesIRQ interrupts can be set
  - Detection of low level, high level, rising edge, or falling edge
  - Interrupt request signal can be output (IRQOUT pin)

    Bus mastership can be required by signaling the external bus master that the external interrupt and on-chip peripheral module interrupt requests have been generated
  - Interrupts can be enabled or disabled
    - Interrupts can be enabled or disabled individually for each interrupt source with the interrupt mask registers and interrupt mask clear registers.

Figure 8.1 shows a block diagram of the INTC.

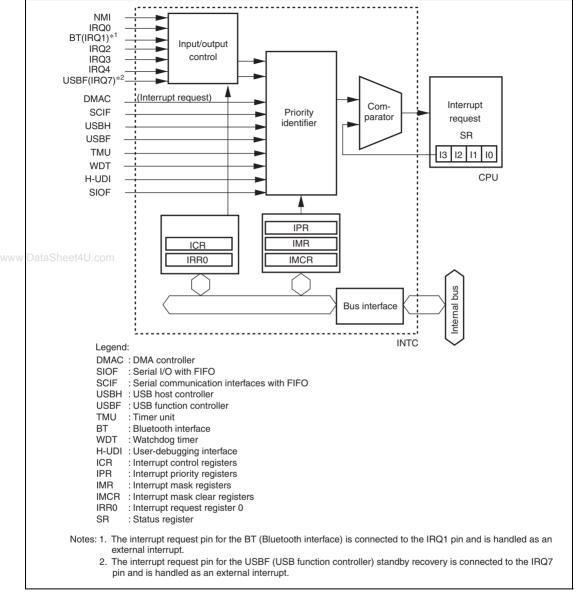

Figure 8.1 Block Diagram of INTC

# 8.2 Input/Output Pins

Table 8.1 shows the INTC pin configuration.

**Table 8.1** Pin Configuration

Pin Name	I/O	Description		
NMI	Input	Nonmaskable Interrupt Input		
		Input of interrupt request signal which is not maskable		
IRQ7, IRQ4 to IRQ0*1	Input	Interrupt Input		
		Input of interrupt request signal		
IRQOUT*2	Output	Bus Mastership Request Output		
		Signal of interrupt request generation		

Notes: 1. IRQ1 is used as the bluetooth interface interrupt request pin and does not support an external pin function. IRQ7 is used as the standby recovery interrupt request pin and does not support an external pin function.

www.DataSheet42: When the NMI or H-UDI interrupt request is generated and the response time of CPU is short, this pin may not be asserted.

# **8.3** Register Descriptions

The INTC has the following registers. For details on register addresses and register states during each processing, refer to section 27, List of Registers.

- Interrupt control register 0 (ICR0)
- Interrupt control register 1 (ICR1)
- Interrupt control register 2 (ICR2)
- Interrupt priority register A (IPRA)
- Interrupt priority register B (IPRB)
- Interrupt priority register C (IPRC)
- Interrupt priority register D (IPRD)
- Interrupt priority register E (IPRE)
- Interrupt priority register F (IPRF)
- Interrupt priority register G (IPRG)
- Interrupt priority register H (IPRH)
- Interrupt request register 0 (IRR0)
- Interrupt mask register 0 (IMR0)
- Interrupt mask register 1 (IMR1)
- Interrupt mask register 4 (IMR4)
- Interrupt mask register 5 (IMR5)
- Interrupt mask register 6 (IMR6)

- Interrupt mask register 9 (IMR9)
- Interrupt mask clear register 0 (IMCR0)
- Interrupt mask clear register 1 (IMCR1)
- Interrupt mask clear register 4 (IMCR4)
- Interrupt mask clear register 5 (IMCR5)
- Interrupt mask clear register 6 (IMCR6)
- Interrupt mask clear register 9 (IMCR9)

# 8.3.1 Interrupt Priority Registers A to H (IPRA to IPRH)

IPRA to IPRH are 16-bit readable/writable registers in which priority levels from 0 to 15 are set for on-chip peripheral module and IRQ interrupts.

Bit	Bit Name	Initial Value	R/W	Description
15	IPR15	0	R/W	These bits set the priority level for each interrupt
DataSh 14	neet4U.com IPR14	0	R/W	source in 4-bit units. For details, see table 8.2,
13	IPR13	0	R/W	Interrupt Sources and IPRA to IPRH.
12	IPR12	0	R/W	
11	IPR11	0	R/W	<del></del>
10	IPR10	0	R/W	
9	IPR9	0	R/W	
8	IPR8	0	R/W	
7	IPR7	0	R/W	<del></del>
6	IPR6	0	R/W	
5	IPR5	0	R/W	
4	IPR4	0	R/W	
3	IPR3	0	R/W	<del></del>
2	IPR2	0	R/W	
1	IPR1	0	R/W	
0	IPR0	0	R/W	

Table 8.2 Interrupt Sources and IPRA to IPRH

Register	Bits 15 to 12	Bits 11 to 8	Bits 7 to 4	Bits 3 to 0
IPRA	TMU0	TMU1	TMU2	Reserved*1
IPRB	WDT	Reserved*1	Reserved*1	Reserved*1
IPRC	IRQ3	IRQ2	IRQ1(for BT)*2	IRQ0
IPRD	IRQ7(for USBF standby recovery interrupt request signal) *3	Reserved* <sup>1</sup>	Reserved* <sup>1</sup>	IRQ4
IPRE	DMAC	Reserved*1	Reserved*1	Reserved*1
IPRF	Reserved*1	Reserved*1	USBF	USBH
IPRG	SCIF0	SCIF1	Reserved*1	Reserved*1
IPRH	Reserved*1	SIOF	Reserved*1	Reserved*1

Notes: 1. Always read as 0. The write value should always be 0. If 1 is written to the bit, correct operation cannot be guaranteed.

- www.DataSheet42.cqRQ1 is connected to the bluetooth interface (BT) interrupt request signal and cannot be used for other functions.
  - 3. IRQ7 is connected to the USBF (USB function controller) standby recovery interrupt request signal and cannot be used for other functions.

As shown in table 8.2, on-chip peripheral module or IRQ interrupts are assigned to four 4-bit groups in each register. These 4-bit groups (bits 15 to 12, bits 11 to 8, bits 7 to 4, and bits 3 to 0) are set with values from H'0 (0000) to H'F (1111). Setting H'0 means priority level 0 (masking is requested); H'F means priority level 15 (the highest level).

# 8.3.2 Interrupt Control Register 0 (ICR0)

ICR0 is a register that sets the input signal detection mode of external interrupt input pin NMI, and indicates the input signal level at the NMI pin.

			Initial		
	Bit	Bit Name	Value	R/W	Description
	15	NMIL	0/1*	R	NMI Input Level
					Sets the level of the signal input at the NMI pin. This bit can be read from to determine the NMI pin level. This bit cannot be modified.
					0: NMI input level is low
					1: NMI input level is high
	14 to 9	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
/ . L	8	NMIE	0	R/W	NMI Edge Select
					Selects whether the falling or rising edge of the interrupt request signal at the NMI pin is detected.
					Interrupt request is detected at the falling edge of NMI input
					Interrupt request is detected at the rising edge of NMI input
	7 to 0	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

Note: \* 1 when NMI input is high, 0 when NMI input is low.

# 8.3.3 Interrupt Control Register 1 (ICR1)

ICR1 is a 16-bit register that specifies the detection mode for external interrupt input pins IRQ4 to IRQ0 individually: rising edge, falling edge, high level, or low level.

Bit	Bit Name	Initial Value	R/W	Description
15	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
14	IRQE*	1	R/W	Interrupt Request Enable
				Enables or disables the use of pins IRQ7, IRQ4 to IRQ0 as six independent interrupt pins.
				0 : Use of pins IRQ7, IRQ4 to IRQ0 as six independent interrupt pins enabled
DataSheet4U.com				1 : Use of pins IRQ7, IRQ4 to IRQ0 as interrupt pins disabled
13 to	10 —	All 0 R		Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description				
9	IRQ41S	0	R/W	IRQn Sense	Select			
8	IRQ40S	0	R/W			ner interrupt request signals		
7	IRQ31S	0	R/W	-		RQ4 to IRQ0 are detected by a		
6	IRQ30S	0	R/W	rising edge, falling edge, high level, or low level.				
5	IRQ21S	0	R/W	Bit 2n+1	Bit 2n	_		
4	IRQ20S	0	R/W	IRQn1S	IRQn0S			
3	IRQ11S	0	R/W	0	0	Interrupt request is detected at the falling edge of IRQn		
2	IRQ10S	0	R/W			input		
1	IRQ01S	0	R/W	0	1	Interrupt request is detected		
0	IRQ00S	0	R/W			at the rising edge of IRQn input		
				1	0	Interrupt request is detected on low level of IRQn input		
	et4U.com			1	1	Interrupt request is detected on high level of IRQn input		

Legend: n = 0 to 4

Note:

The IRQE bit must be cleared to 0 before the BL bit in the status register (SR) is cleared to 0 in the initialization routine after reset, and must then not be changed. If the IRQE bit is set to 1 when the BL bit is cleared to 0, correct operation cannot be guaranteed.

# 8.3.4 Interrupt Control Register 2 (ICR2)

ICR2 is a 16-bit register that specifies the detection mode for the external interrupt input pin IRQ7: rising edge, falling edge, high level, or low level.

Bit	Bit Name	Initial Value	R/W	Description			
15 to 4	_	All 0	R	Reserved			
					If 1 is writ	as 0. The write value should ten to these bits, correct aranteed.	
3	IRQ71S	0	R/W	IRQ7 Sense	Select		
2	IRQ70S	0	R/W	These bits select whether interrupt request signals corresponding to pin IRQ7 are detected by a rising edge, falling edge, high level, or low level.			
				Bit 2n+1	Bit 2n	_	
DataSheet4				IRQ71S	IRQ70S		
				0	0	Interrupt request (USBF standby recovery interrupt request) is detected at the falling edge of IRQ7 input	
				0	1	Setting prohibited	
				1	0	Setting prohibited	
				1	1	Setting prohibited	
reques to 12 i and th			e: When the USBF standby recovery interrupt request need not to be detected, clear the bits 15 to 12 in IPRD to 0 or set the bit 7 in IMR0 to 1, and the IRQ7 interrupt request should be masked.				
1	_	All 0	R	Reserved			
0				These bits are always read as 0. The write value should always be 0 or the bit7 in IMR0 should be set to 1. If 1 is written to these bits, correct operation cannot be guaranteed.			

# 8.3.5 Interrupt Request Register 0 (IRR0)

IRR0 is an 8-bit register that indicates interrupt requests from external input pins IRQ7, IRQ4\* to IRQ0.

Note: \* In this LSI, IRQ7 and IRQ1 are used specific to internal module and cannot function as external pins.

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ7R*2	0	R/W	IRQn Interrupt Request
6* <sup>1</sup>	_	0	R	Indicates whether there is interrupt request input to the
5*¹	_	0	R	IRQn pin. When edge-detection mode is set for IRQn, an interrupt request is cleared by writing 0 to the
4	IRQ4R*2	0	R/W	IRQnR bit after reading IRQnR = 1.
3	IRQ3R*2	0	R/W	When level-detection mode is set for IRQn, these bits
2	IRQ2R*2	0	R/W	indicate whether an interrupt request is input. The
w.DataShe	IRQ1R*2	0	R/W	interrupt request is set/cleared by only 1/0 input to the IRQn pin.
0	IRQ0R*2	0	R/W	IRQnR
				0: No interrupt request input to IRQn pin
				1: Interrupt request input to IRQn pin
				Legend: $n = 0$ to 4, 7

- Notes: 1. Bits 6 to 5 are reserved bits. These bits are always read as undefined value. The write value should always be 0. If 1 is written to the bits, correct operation cannot be guaranteed.
  - 2. The IRQ7R, IRQ4R to IRQ0R bits are cleared to 0 after the IRQE bit in the interrupt control register 1 (ICR1) is cleared to 0 in the initialization routine after reset.

# 8.3.6 Interrupt Mask Registers 0, 1, 4 to 6, and 9 (IMR0, IMR1, IMR4 to IMR6, and IMR9)

IMR0, IMR1, IMR4 to IMR6, and IMR9 are 8-bit readable/writable registers that mask the IRQ and on-chip peripheral module interrupts. When an interrupt source is masked, interrupt requests may be mistakenly detected, depending on the operation state of the IRQ pins and on-chip peripheral modules. To prevent this, set IMR0, IMR1, IMR4 to IMR6, and IMR9 while no interrupts are set to be generated, and then read the new settings from these registers.

Table 8.3 shows the relationship between IMR and each interrupt source.

Bit	Bit Name	Initial Value	R/W	Descri	ption			
7	IM7	0	R/W	Interrup	ot Mask			
6 5	IM6 IM5	0 0	R/W R/W	Table 8.3 lists the correspondence between the interrupt sources and interrupt mask registers.				
4	IM4	0	R/W	IMn	Read	Write		
3	IM3	0	R/W	1	Interrupt source of the corresponding bit is masked			
2	IM2	0	R/W					
1	IM1	0	R/W	0	Interrupt source of the corresponding bit is not	No processing		
0	IMO	0	R/W		masked	proceeding		
				Legend: n = 7 to 0				

Table 8.3 Correspondence between Interrupt Sources and IMR0 to IMR9/IMCR0 to IMCR9

Register		Bit Name (Function Name)									
Name	7	6	5	4	3	2	1	0

IMR9/IMCR9	_	_	_	_	_	USBFI1	USBFI0	USBHI			
		_		_		(USBF)		(USBH)			

Note: —: Reserved. These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

# 8.3.7 Interrupt Mask Clear Registers 0, 1, 4 to 6, and 9 (IMCR0, IMCR1, IMCR4 to IMCR6, and IMCR9)

IMCR0, IMCR1, IMCR4 to IMCR6, and IMCR9 are 8-bit writable registers that clear the mask settings for the IRQ and on-chip peripheral module interrupts. Table 8.3 shows the relationship between IMCR and each interrupt source.

Bit	Bit Name	Initial Value	R/W	Description
7	IMC7	_	W	Interrupt Mask Clear
6	IMC6	_	W	Table 8.3 lists the correspondence between interrupt
5	IMC5	_	W	sources and interrupt mask clear registers.

1	IMC1	_	W	0 No processing
DataShe 0	et4U.com IMC0	_	W	Legend: $n = 7$ to 0

# 8.4 Interrupt Sources

There are three types of interrupt sources: NMI, IRQ, and on-chip peripheral modules. Each interrupt has a priority level (0 to 16), with 1 the lowest and 16 the highest. Priority level 0 masks an interrupt, so the interrupt request is ignored.

## 8.4.1 NMI Interrupt

The NMI interrupt has the highest priority level of 16. When the BL bit in the status register (SR) is 0, NMI interrupts are accepted. NMI interrupts are edge-detected. In sleep or standby mode, the interrupt is accepted regardless of the BL setting. The NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is used to select either rising or falling edge detection.

When using edge-input detection for NMI interrupts, a pulse width of at least two  $P\phi$  cycles (peripheral clock) is necessary. NMI interrupt exception handling does not affect the interrupt mask level bits (I3 to I0) in the status register (SR).

.DataSheet4U.com

It is possible to wake the chip up from sleep mode or standby mode with an NMI interrupt.

# 8.4.2 IRQ Interrupts

IRQ interrupts are input by level or edge from pins IRQ7, IRQ4 to IRQ0. The priority level can be set by interrupt priority registers C and D (IPRC and IPRD) in a range from 0 to 15.

When using edge-sensing for IRQ interrupts, clear the interrupt source by having software read 1 from the corresponding bit in IRR0, then write 0 to the bit.

When the ICR1 and ICR2 registers are rewritten, IRQ interrupts may be mistakenly detected, depending on the IRQ pin states. To prevent this, rewrite the register while interrupts are masked, then release the mask after clearing the illegal interrupt by writing 0 to IRR0 after reading IRR0.

Edge input interrupt detection requires input of a pulse width of more than two cycles on a peripheral clock  $(P\phi)$  basis.

When using level-sensing for IRQ interrupts, the pin levels must be retained until the CPU samples the pins. Therefore, the interrupt source must be cleared by the interrupt handler.

The interrupt mask bits (I3 to I0) in the status register (SR) are not affected by IRQ interrupt handling.

# 8.4.3 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following modules\*:

- DMA controller (DMAC)
- Serial I/O with FIFO (SIOF)
- Serial communication interfaces with FIFO (SCIF0 and SCIF1)
- USB host controller (USBH)
- USB function controller (USBF)
- Timer unit (TMU)
- Watchdog timer (WDT)
- User-debugging interface (H-UDI)

Note: \* An interrupt generated at the bluetooth interface (BT) is not handles as a on-chip peripheral module interrupt and is connected to the eternal interrupt pin (IRQ1) of this LSI. The USB function controller (USBF) standby recovery interrupt is not handled as <a href="https://www.DataSheet4U">www.DataSheet4U</a> acon-chip peripheral module interrupt and is connected to the external interrupt pin (IRO7) of this LSI.

Not every interrupt source is assigned a different interrupt vector. Sources are reflected in the interrupt event register 2 (INTEVT2). It is easy to identify sources by using the value of the INTEVT2 register as a branch offset.

A priority level (from 0 to 15) can be set for each module except H-UDI by writing to interrupt priority registers A to H (IPRA to IPRH). The priority level of the H-UDI interrupt is 15 (fixed).

The interrupt mask bits (I3 to I0) in the status register are not affected by on-chip peripheral module interrupt handling.

# 8.4.4 Interrupt Exception Handling and Priority

There are three types of interrupt sources: NMI, IRQ, and on-chip peripheral modules. The priority of each interrupt source is set within priority levels 0 to 15; level 15 is the highest and level 1 is the lowest. When the priority is set to level 0, that interrupt is masked and the interrupt request is ignored.

Table 8.4 lists the codes for the interrupt event register 2 (INTEVT2) and the order of interrupt priority.

Each interrupt source is assigned a unique code by INTEVT2. The start address of the interrupt service routine is common for each interrupt source. This is why, for instance, the value of INTEVT2 is used as an offset at the start of the interrupt service routine and branched to in order to identify the interrupt source.

www.DataSheet4U.com

Rev. 1.00, 02/04, page 212 of 804

IRQ interrupt and on-chip peripheral module interrupt priorities can be set properly between 0 and 15 for each module by setting interrupt priority registers A to C and F to H (IPRA to IPRC and IPRF to IPRH). A reset assigns priority level 0 to IRQ and on-chip peripheral module interrupts.

If the same priority level is assigned to two or more interrupt sources and interrupts from those sources occur simultaneously, their priority order is the default priority order indicated at the right in table 8.4.

**Table 8.4** Interrupt Exception Handling Sources and Priority

Interrupt	Source	Interrupt Code	Interrupt Priority (Initial Value)	IPR (Bit Numbers)	Priority within IPR Setting Unit	Default Priority
NMI		H'1C0	16	_	_	High

# 8.5 Operation

# 8.5.1 Interrupt Sequence

The sequence of interrupt operations is described below. Figure 8.2 is a flowchart of the operations.

- 1. The interrupt request sources send interrupt request signals to the interrupt controller.
- 2. The interrupt controller selects the highest-priority interrupt from the interrupt requests sent, following the priority levels set in interrupt priority registers A to H (IPRA to IPRH). Lower priority interrupts are held pending. If two of these interrupts have the same priority level or if multiple interrupts occur within a single module, the interrupt with the highest priority is selected, according to table 8.4, Interrupt Exception Handling Sources and Priority.
- 3. The priority level of the interrupt selected by the interrupt controller is compared with the interrupt mask bits (I3 to I0) in the status register (SR) of the CPU. If the request priority level is higher than the level in bits I3 to I0, the interrupt controller accepts the interrupt and sends www.DataSan interrupt request signal to the CPU.
  - 4. Detection timing: The INTC operates, and notifies the CPU of interrupt requests, in synchronization with the peripheral clock (Pφ). The CPU receives an interrupt at a break in instructions.
  - 5. The interrupt source code is set in the interrupt event register 2 (INTEVT2).
  - 6. The status register (SR) and program counter (PC) are saved to SSR and SPC, respectively.
  - 7. The block bit (BL), register bank bit (RB), and mode bit (MD) in SR are set to 1.
  - 8. The CPU jumps to the start address of the interrupt handler (the sum of the value set in the vector base register (VBR) and H'00000600). This jump is not a delayed branch. The interrupt handler may branch with the INTEVT2 register value as its offset in order to identify the interrupt source. This enables it to branch to the handling routine for the individual interrupt source.
  - Notes: 1. The interrupt mask bits (I3 to I0) in the status register (SR) are not changed by acceptance of an interrupt in this LSI.
    - 2. The interrupt source flag should be cleared in the interrupt handler. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag after it has been cleared, and then execute an RTE instruction.

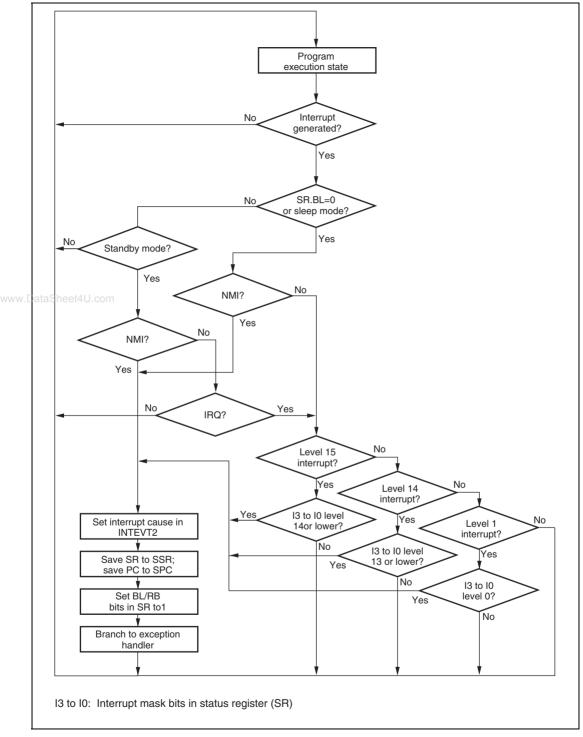

Figure 8.2 Interrupt Operation Flowchart www.DataSheet4U.com

## 8.5.2 Multiple Interrupts

When handling multiple interrupts, an interrupt handler should include the following procedures:

- 1. Branch to a specific interrupt handler corresponding to a code set in INTEVT2. The code in INTEVT2 can be used as an offset for branching to the specific handler.
- 2. Clear the interrupt source in each specific handler.
- 3. Save SSR and SPC to memory.
- 4. Clear the BL bit in SR, and set the accepted interrupt level in the interrupt mask bits in SR.
- 5. Handle the interrupt.
- 6. Execute the RTE instruction.

When the sequence of interrupt operations is described above, if an interrupt of higher priority than the one being handled occurs directly after execution of the operation in step 4, it can be accepted.

www.DataSheet4U.con

# Section 9 Bus State Controller (BSC)

### 9.1 Overview

The bus state controller (BSC) outputs control signals for various types of memory that is connected to the external address space and external devices. BSC functions enable this LSI to connect directly with SRAM, SDRAM, and other memory storage devices, and external devices.

### 9.1.1 Features

The BSC has the following features:

1. Physical address space is divided into eight areas

A maximum 16 Mbytes for each of the three areas, CS0, CS3, and CS4, totally 48 Mbytes.

Can specify the normal space interface, SRAM interface with byte selection, burst ROM interface, www.DataSh.and SDRAM interface\*<sup>1</sup>

Can select the data bus width (8 or 16 bits) for each address space\*2.

Controls the insertion of the wait state for each address space.

Controls the insertion of the wait state for each read access and write access.

Can set the independent idling cycle in the continuous access for five cases: read-write (in same space/different space), read-read (in same space/different space), the first cycle is a write access.

2. Normal space interface

Supports the interface that can directly connect to the normal memories such as SRAM and ROM.

3. Burst ROM interface

High-speed access to the ROM that has the page mode function (page flash ROM).

### 4. SDRAM interface

Can set the SDRAM in CS3 area.

Multiplex output for row address/column address.

Efficient access by single read/single write.

High-speed access by the bank-active mode.

Supports an auto-refresh and self-refresh.

5. Byte-selection SRAM interface

Can connect directly to a byte-selection SRAM

6. Bus arbitration

Shares all of the resources with other CPU and outputs the bus enable after receiving the bus request from external devices.

7. Refresh function

Supports the auto-refresh and self-refresh functions.

Specifies the refresh interval using the refresh counter and clock selection

Can execute concentrated refresh by specifying the refresh counts (1, 2, 4, 6, or 8)

Notes: 1. Some CSn arias do not support the some memory interfaces. For the sorts of memory interfaces that are supported by each area, see section 9.3, Area Overview.

2. The data bus width of the CS0 area is 16-bit fixed.

### 9.3 Area Overview

#### 9.3.1 Area Division

In the architecture of this LSI, the logical spaces have 32-bit address spaces. The cache access method is shown by the upper three bits. For details see section 5, Cache. The remaining 29 bits are mapped in 512-Mbyte physical address space that are used for division of the space into eight areas. The BSC performs control for this 29-bit physical space. Figure 9.2 shows the mapping from the logical address space to the physical address space. Area 1 is used for the internal I/O, and area 2 and area 5 to area 7 are reserved. The other three areas (area 0, area 3, and area 4) are used as external address spaces.

As listed in table 9.2, this LSI can connect each type of memories to three area of an external address space among the physical address spaces divided into eight areas, respectively. And it outputs chip select signals  $(\overline{CS0}, \overline{CS3}, \text{ and } \overline{CS4})$  for each of them.  $\overline{CS0}$  is asserted during area 0 access;  $\overline{CS4}$  is asserted during area 4 access.

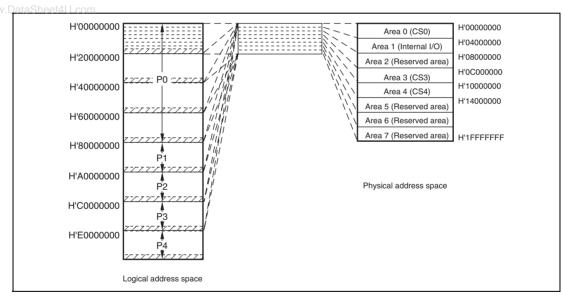

Figure 9.2 Logical Address Space and Physical Address Space

### 9.3.2 Shadow Area

Areas 0, 3, and 4 are decoded by physical addresses A28 to A26, which correspond to areas B'000, B'011, and B'100. Address bits A31 to A29 are ignored. This means that the range of area 0 addresses, for example, is H'00000000 to H'03FFFFFF, and its corresponding shadow space is the address space obtained by adding to it H'20000000  $\times$  n (n = 1 to 6). Addresses A25 and A24 are ignored since addresses A23 to A0 are supported for the external pins of the address bus. Accordingly, for example, H'01000000 to H'03FFFFFF in the area 0 is shadow space.

Area P4 (H'E0000000 to H'FFFFFFF) is an internal I/O area and is assigned for internal register addresses. Area P4 does not become shadow space.

www.DataSheet4U.con

## 9.3.3 Address Map

The external address space has a capacity of 48 Mbytes and is used by dividing three partial spaces. The kind of memory to be connected and the data bus width are specified in each partial space. The address map for the external address space is listed in table 9.2.

Table 9.2 Address Space Map of External Address Space

Area	Memory to be Connected	Physical Address	Capacity	Access Size
Area 0	Normal memory*1	H'00000000 to H'00FFFFFF	16 Mbytes	8, 16, 32* <sup>2</sup>
(CS0 area)	Burst ROM	H'01000000 to H'03FFFFFF	Shadow	_
		H'00000000 + H'20000000 × n to H'03FFFFFF + H'20000000 × n	Shadow	(n = 1 to 6)
Area 1	Internal I/O	H'04000000 to H'07FFFFF		
ataSheet4U.co		H'04000000 + H'20000000 × n to H'07FFFFFF + H'20000000 × n		(n = 1 to 6)
Area 2	Reserved area*4	H'08000000 + H'20000000 × n to H'0BFFFFFF + H'20000000 × n		(n = 1 to 6)
Area 3	SRAM SDRAM Normal memory*1	H'0C000000 to H'0CFFFFF	16 Mbytes	8, 16, 32* <sup>3</sup>
(CS3 area)		H'0D000000 to H'0FFFFFF	Shadow	
		H'0C000000 + H'20000000 × n to H'0FFFFFF + H'20000000 × n	Shadow	(n = 1 to 6)
Area 4		H'10000000 to H'10FFFFF	16 Mbytes	8, 16, 32* <sup>3</sup>
(CS4 area)		H'11000000 to H'13FFFFFF	Shadow	
	Byte-selection SRAM	H'10000000 + H'20000000 × n to H'13FFFFFF + H'20000000 × n	Shadow	(n = 1 to 6)
Area 5	Reserved area*4	H'14000000 + H'20000000 × n to H'17FFFFFF + H'20000000 × n		(n = 1 to 6)
Area 6	Reserved area*4	H'18000000 + H'0000000 × n to H'1BFFFFFF + H'20000000 × n		(n = 0 to 6)
Area 7	Reserved area*4	H'1C000000 + H'20000000 × n to H'1FFFFFF + H'20000000 × n		(n = 0 to 7)

Notes: 1. Normal memory can be connected to the external device which has an interface, such as the SRAM and ROM.

- 2. In the area 0 (selected when the chip select signal  $\overline{\text{CS0}}$  is asserted), the data bus width is 16-bit fixed.
- 3. The data bus width is set by the CSn space bus control register (CSnBCR). The data bus width should be 16 bits when SDRAM is connected in area 3.
- 4. Do not access the reserved area. If the reserved area is accessed, the correct operation cannot be guaranteed.

### 9.3.4 Data Bus Width

The data bus width of areas 3 and 4 is set 8 bits or 16 bits by the CSn space bus control register (CSnBCR, n = 3 or 4). The data bus width of area 0 is fixed 16 bits. For details, see section 9.4.2, CSn Space Bus Control Register.

# 9.4 Register Descriptions

The BSC has the following registers. Refer to section 27, List of Registers, for the register addresses and the register states in each operating mode.

Do not access spaces other than CS0 until the termination of the setting the memory interface. When accessing spaces other than CS0, set the CSn space bus control register (CSnBCR) which corresponds to the area to be accessed before setting the CSn space wait control register (CSnWCR).

- Common control register (CMNCR)
- CS0 space bus control register (CS0BCR)
- CS3 space bus control register (CS3BCR)
- CS4 space bus control register (CS4BCR)
- CS0 space wait control register (CS0WCR)
- CS3 space wait control register (CS3WCR)
- CS4 space wait control register (CS4WCR)
- SDRAM control register (SDCR)
- Refresh timer control/status register (RTCSR)
- Refresh timer counter (RTCNT)
- Refresh time constant register (RTCOR)
- Reset wait counter (RWTCNT)
- SDRAM mode register for CS3 space (SDMR3)\*

Note: \* Substance of this register is in the SDRAM, and can be written to by accessing the area of this register. For details, see Power-On Sequence in section 9.5.5, SDRAM Interface.

# 9.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the common items for each area. CMNCR is initialized by a power-on reset, but not by a manual reset or in standby mode and holds the previous value. Do not access external memory other than area 0 until the CMNCR register initialization is complete.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 8	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
7	DMAIW1	0	R/W	Wait states between access cycles when DMA single
6	DMAIW0	0	R/W	address transfer is performed
				Specify the number of idle cycles to be inserted after an access to an external device with DACK when DMA single address transfer is performed. The method of inserting idle cycles depends on the contents of DMAIWA.
				00: No idle cycle inserted
				01: 1 idle cycle inserted
				10: 2 idle cycles inserted
				11: 4 idle cycled inserted
5	DMAIWA	0	R/W	Method of inserting wait states between access cycles when DMA single address transfer is performed
				Specifies the method of inserting the idle cycles specified by the DMAIW1 and DMAIW0 bits. Clearing this bit will make this LSI insert the idle cycles when another device, which includes this LSI, drives the data bus after an external device with DACK drove it. Setting this bit will make this LSI insert the idle cycles even when the continuous accesses to an external device with DACK are performed.
				<ol> <li>Idle cycle is inserted when other device drives the data bus after an external device with DACK drives the data bus.</li> </ol>
				<ol> <li>Idle cycle is inserted every time when an external device with DACK is accessed.</li> </ol>
4	_	1	R	Reserved
				This bit is always read as 1. The write value should always be 1. When 0 is written to this bit, correct operation cannot be guaranteed.

		Initial		
Bit	Bit Name	Value	R/W	Description
3	ENDIAN	0/1*	R	Endian Flag
				Samples the external pin for specifying endian on power-on reset (MD5) and specifies the pin value as the initial value. All address spaces are defined by this bit. This is a read-only bit.
				<ol> <li>The external pin for specifying endian (MD5) was low level on power-on reset. This LSI is being operated as big endian.</li> </ol>
				1: The external pin for specifying endian (MD5) was high level on power-on reset. This LSI is being operated as little endian.
2	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
DataShee	t4HIZMEM	0	R/W	High-Z Memory Control
				Specifies the pin state in standby mode for A23 to A0, $\overline{BS}$ , $\overline{CSn}$ , RD/ $\overline{WR}$ , $\overline{WEn}$ /DQMn, and $\overline{RD}$ .
				0: High impedance in standby mode.
				1: Driven in standby mode
0	HIZCNT	0	R/W	High-Z Control
				Specifies the state in standby mode and bus released for CKIO, CKE, $\overline{\text{RAS}}$ , and $\overline{\text{CAS}}$ .
				0: High impedance in standby mode and bus released for CKIO, CKE, $\overline{RAS}$ , and $\overline{CAS}$ .
				1: Driven in standby mode and bus released for CKIO, CKE, $\overline{\text{RAS}},$ and $\overline{\text{CAS}}.$

Note: \* The external pin for specifying endian (MD5) is sampled on power-on reset. When big endian is specified, this bit is read as 0 and when little endian is specified, this bit is read as 1.

# 9.4.2 CSn Space Bus Control Register (CSnBCR) (n=0, 3, 4)

CSnBCR is a 32-bit readable/writable register that specifies the memory to be connected to each area, the number of idle cycles between bus cycles, and the bus-width.

CSnBCR is initialized by a power-on reset, but not by a manual reset or in standby mode and holds the previous value. Do not access external memory other than area 0 until CSnBCR register initialization is completed.

9	BSZ0	0/1	R/W	Specify	the data bus sizes of spaces.
				The dat	ta bus sizes of areas 3 and 4 are shown below.
				00: Set	ting prohibited
				01: 8-bi	t size
				10: 16-l	bit size
				11: Set	ting prohibited
				Note:	The initial values of CS0BCR and other CSnBCR are 10 and 11, respectively. The valid value should be set.  The data bus width of the area 0 is fixed 16 bits.
					Other settings are ignored.
8 to 0	_	All 0	R	Reserve	ed
	et4U.com			always	bits are always read as 0. The write value should be 0. If 1 is written to these bits, correct operation be guaranteed.

Notes: 1. In actual operation, same idle cycles might be inserted by factors other than the specification of this bit.

- 2. If an unappropriated memory is specified to be connected to a space, correct operation cannot be guaranteed.
- 3. The initial data bus sizes of other than area 0 after a reset cannot be set. Therefore, the data bus sizes should be set 8 or 16 bits before the areas are accessed.

## 9.4.3 CSn Space Wait Control Register (CSnWCR) (n=0, 3, 4)

CSnWCR is a 32-bit register which specifies various wait cycles for memory accesses. The bit configuration of this register varies as shown below according to the memory type specified by the CSn space bus control register (CSnBCR). Specify CSnBCR register first, then specify the CSnWCR register.

CSnWCR is initialized by a power-on reset, but not by a manual reset or in standby mode and holds the previous value.

## Normal Space, Byte-Selection SRAM:

## 9.4.4 SDRAM Control Register (SDCR)

SDCR is a 32-bit register that specifies the method to refresh and access SDRAM, and the types of SDRAMs to be connected.

SDCR is initialized by a power-on reset, but not by a manual reset or in standby mode and holds the previous value. Bits other than RFSH and RMODE should be written to at the initialization settings and not be changed afterward. When writing to RFSH and RMODE, the values before writing should be written to the other bits. The area 3 should not be accessed until this register setting has been completed while the synchronous DRAM is used.

	Bit	Bit Name	Initial Value	R/W	Description
•	31 to 13	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
.D	12	SLOW	0	R/W	Low-Frequency Mode
					Specifies the output timing of command, address, and write data for SDRAM and the latch timing of read data from SDRAM. Setting this bit makes the hold time for command, address, write and read data. This mode is suitable for SDRAM with low-frequency clock.
					0: Command, address, and write data for SDRAM is output at the rising edge of CKIO. Read data from SDRAM is latched at the rising edge of CKIO.
					1: Command, address, and write data for SDRAM is output at the falling edge of CKIO. Read data from SDRAM is latched at the falling edge of CKIO.
	11	RFSH	0	R/W	Refresh Control
					Specifies whether or not the refresh operation of the SDRAM is performed.
					0: No refresh
					1: Refresh

Bit	Bit Name	Initial Value	R/W	Description
10	RMODE	0	R/W	Refresh Control
				Specifies whether to perform auto-refresh or self-refresh when the RFSH bit is 1. When the RFSH bit is 1 and this bit is 1, self-refresh starts immediately. When the RFSH bit is 1 and this bit is 0, auto-refresh starts according to the contents that are set in registers RTCSR, RTCNT, and RTCOR.
				0: Auto-refresh is performed
				1: Self-refresh is performed
9	PDOWN	0	R/W	Power-Down Mode
				Specifies whether the SDRAM is entered in power-down mode or not after the memory access other than SDRAM is completed. If this bit is set to 1, the CKE pin is pulled to low to place the SDRAM to power-down mode triggered by memory access other than SDRAM after the SDRAM access ends.
	t4U.com			0: Does not place the SDRAM in power-down mode.
				1: Places the SDRAM in power-down mode.
8	BACTV	0	R/W	Bank Active Mode
				Specifies to access whether in auto-precharge mode (using READA and WRITA commands) or in bank active mode (using READ and WRIT commands).
				0: Auto-precharge mode (using READA and WRITA commands)
				1: Bank active mode (using READ and WRIT commands)
				Note: When bank active mode is specified, the data bus width should be set 16 bits.
7 to 5	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
4	A3ROW1	0	R/W	Number of Bits of Row Address
3	A3ROW0	0	R/W	Specify the number of bits of the row address.
				00: 11 bits
				01: 12 bits
				10: 13 bits
				11: Reserved (setting prohibited)

Bit	Bit Name	Initial Value	R/W	Description

# 9.4.5 Refresh Timer Control/Status Register (RTCSR)

RTCSR is a 32-bit readable/writable register that specifies various items about refresh for SDRAM. When the RTCSR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	_	All 0	R	Write Protection
				These bits are always read as 0. When writing to these bits, the upper 16-bit of the write data should be H'A55A to cancel write protection. The lower 8-bit is should always be 0. If other value is written to these bits, correct operation cannot be guaranteed.
7	CMF	0	R/W	Compare Match Flag
itaSheet4U.				Indicates that a compare match occurs between the refresh timer counter (RTCNT) and refresh time constant register (RTCOR). This bit is set or cleared in the following conditions.
				0: Clearing condition: When 0 is written in CMF after reading out RTCSR during CMF = 1.
				1: Setting condition: When the condition RTCNT = RTCOR is satisfied.
6	_	0	R	Reserved
			This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.	
5	CKS2	0	R/W	Clock Select
4	CKS1	0	R/W	
3	CKS0	0	R/W	(RTCNT).
				000: Stop the counting-up
				001: Bφ/4
				010: B\phi/16
				011: B\phi/64
				100: Bø/256
				101: B\(\phi\)/1024
				110: Bø/2048
				111: Bø/4096

Bit	Bit Name	Initial Value	R/W	Description
2	RRC2	0	R/W	Refresh Count
1	RRC1	0	R/W	Specify the number of continuous refresh cycles, when the
0	RRC0 0 R/W refresh request occurs after the coincidence of the value the refresh timer counter (RTCNT) and the refresh timer		refresh request occurs after the coincidence of the values of the refresh timer counter (RTCNT) and the refresh time constant register (RTCOR). These bits can make the period of occurrence of refresh long.	
				000: Once
				001: Twice
				010: 4 times
				011: 6 times

				111: Setting prohibited

# 9.4.6 Refresh Timer Counter (RTCNT)

RTCNT is an 8-bit counter register that increments using the clock selected by bits CKS2 to CKS0 in RTCSR. When RTCNT matches RTCOR, RTCNT is cleared to 0. The value in RTCNT returns to 0 after counting up to 255. When the RTCNT is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 8	_	All 0	R/W	Write Protection
				These bits are always read as 0. When writing to these bits, the upper 16-bit of the write data should be H'A55A to cancel write protection. The lower 8-bit is should always be 0. If other value is written to these bits, correct operation cannot be guaranteed.
7 to 0	_	All 0	R/W	8-bit Counter

## 9.4.7 Refresh Time Constant Register (RTCOR)

RTCOR is a 32-bit register. When RTCOR matches RTCNT, the CMF bit in RTCSR is set to 1 and RTCNT is cleared to 0.

When the RFSH bit in SDCR is 1, a memory refresh request is issued by this matching signal. This request is maintained until the refresh operation is performed. If the request is not processed when the next matching occurs, the previous request is ignored.

When the RTCOR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	_	All 0	R	Write Protection
taSheet4U.	com			These bits are always read as 0. When writing to these bits, the upper 16-bit of the write data should be H'A55A to cancel write protection. The lower 8-bit is should always be 0. If other value is written to these bits, correct operation cannot be guaranteed.
7 to 0	_	All 0	R/W	Refresh Time
				Specify the upper limit value of the refresh timer counter (RTCNT).

## 9.4.8 Reset Wait Counter (RWTCNT)

RWTCNT is a 7-bit counter. This counter starts to increment by synchronizing the CKIO after a power-on reset is released, and stops when the value reaches H'007F. External bus access is suspended while the counter is operating. This counter is provided to minimize the time from releasing a reset for flash memory to the first access. This register cannot be read or written to.

# 9.5 Operating Description

### 9.5.1 Endian/Access Size and Data Alignment

This LSI supports big endian, in which the 0 address is the most significant byte (MSByte) in the byte data and little endian, in which the 0 address is the least significant byte (LSByte) in the byte data. Endian is specified on power-on reset by the external pin (MD5). When MD5 pin is low level on power-on reset, the endian will become big endian and when MD5 pin is high level on power-on reset, the endian will become little endian.

Two data bus widths (8 bits and 16 bits) are available for normal memory and byte-selection SRAM. Note that the data bus width for the area 0 is fixed 16 bits. The data bus width of SDRAM is fixed 16 bits. Data alignment is performed in accordance with the data bus width of the device and endian. This also means that when longword data is read from a byte-width device, the read operation must be done four times. In this LSI, data alignment and conversion of data length is performed automatically between the respective interfaces.

Table 9.3 through 9.6 show the relationship between endian, device data width, and access unit.

### 9.5.2 Normal Space Interface

**Basic Timing:** For access to a normal space, this LSI uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. When using SRAM with a byte-selection pin, see section 9.5.7, Byte-Selection SRAM Interface. Figure 9.3 shows the basic timings of normal space access. A no-wait normal access is completed in two cycles. The  $\overline{BS}$  signal is asserted for one cycle to indicate the start of a bus cycle.

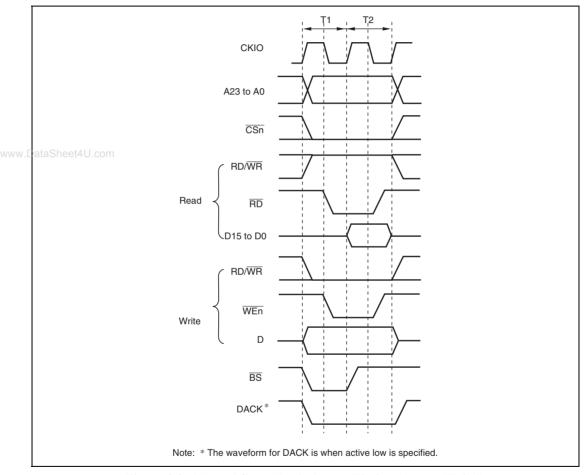

Figure 9.3 Normal Space Basic Access Timing (Access Wait 0)

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 16 bits are always read in case of a 16-bit device, and 8 bits in case of an 8-bit device. When writing, only the  $\overline{\text{WEn}}$  signal for the byte to be written is asserted.

Reading/writing for cache fill or copy back is performed continuously in total of 16 bytes according to the specified data bus width. During the processing, bus is not released. If a cache miss occurs in byte or word operand access or at a branch to an odd word boundary, the CPU performs longword accesses to perform a cache fill operation on the external interface. Writing to the write-through area and reading/writing to the area not to be cached are performed according to the actual access size.

It is necessary to output the data that has been read using the  $\overline{RD}$  signal when a buffer is established in the data bus. The  $\overline{RD}/\overline{WR}$  signal is in a read state (high output) when no access has been carried out. Therefore, care must be taken when controlling the external data buffer, to avoid collision.

Figures 9.4 and 9.5 show the basic timings of normal space accesses. If the WM bit of the CSnWCR is cleared to 0, a Tnop cycle is inserted to evaluate the external wait (figure 9.4). If the WM bit of the CSnWCR is set to 1, external waits are ignored and no Tnop cycle is inserted (figure 9.5).

Figure 9.6 and figure 9.7 shows the examples of SRAM connection. Note that bits of external memory address and those of this LSI address are connected shifted when using the data in longword units (figure 9.6) and in word units (figure 9.7) since this LSI address is divided in byte units.

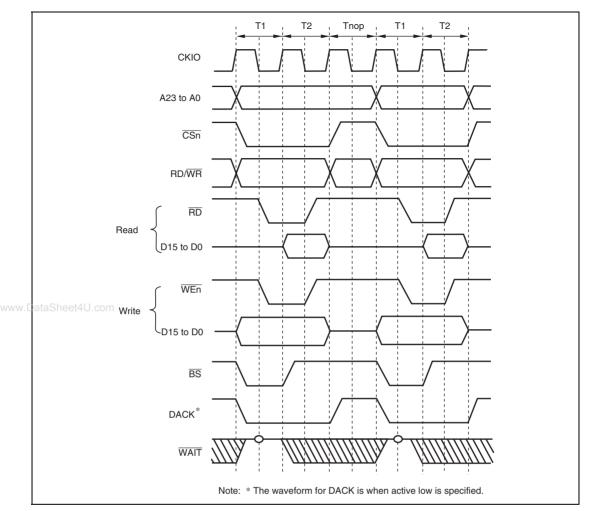

Figure 9.4 Continuous Access for Normal Space 1 Data Bus Width = 16 bits, Long-Word Access, CSnWCR.WN Bit = 0 (Access Wait = 0, Cycle Wait = 0)

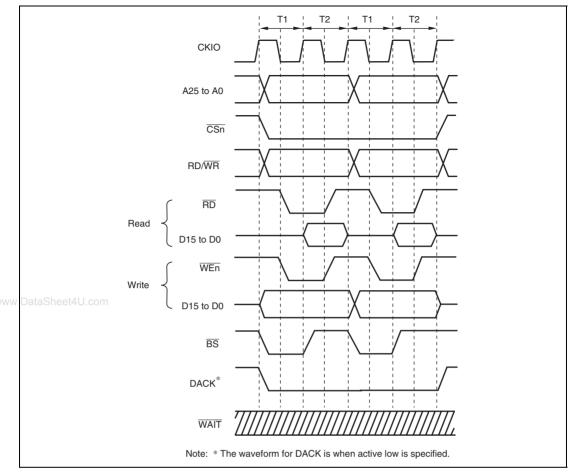

Figure 9.5 Continuous Access for Normal Space 2 Data Bus Width = 16 bits, Long-Word Access, CSnWCR.WN Bit = 1 (Access Wait = 0, Cycle Wait = 0)

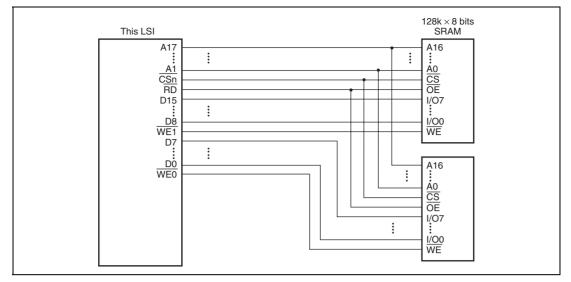

Figure 9.6 Example of 16-Bit Data-Width SRAM Connection

www.DataSheet4LL.com

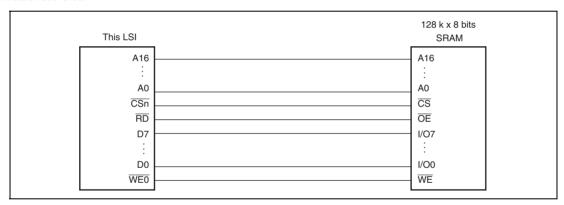

Figure 9.7 Example of 8-Bit Data-Width SRAM Connection

#### 9.5.3 Access Wait Control

Wait cycle insertion on a normal space access can be controlled by the settings of bits WR3 to WR0 in CSnWCR. It is possible for area 4 to insert wait cycles independently in read access and in write access. The areas other than 4 have common access wait for read cycle and write cycle. The specified number of Tw cycles are inserted as wait cycles in a normal space access shown in figure 9.8.

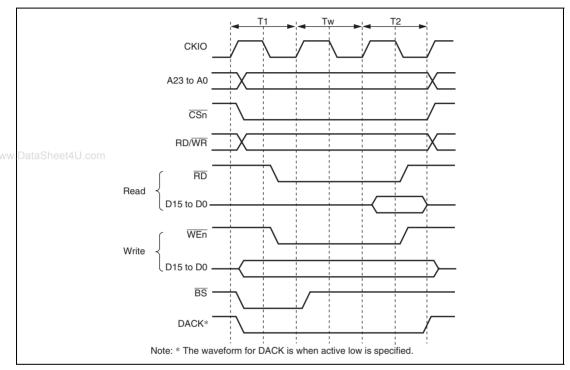

Figure 9.8 Wait Timing for Normal Space Access (Software Wait Only)

When the  $\overline{WM}$  bit in CSnWCR is cleared to 0, the external wait input  $\overline{WAIT}$  signal is also sampled.  $\overline{WAIT}$  pin sampling is shown in figure 9.9. A 2-cycle wait is specified as a software wait. The  $\overline{WAIT}$  signal is sampled on the falling edge of CKIO at the transition from the T1 or Tw cycle to the T2 cycle.

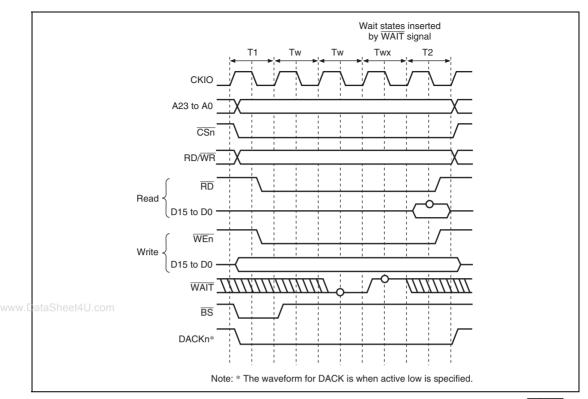

Figure 9.9 Wait State Timing for Normal Space Access (Wait State Insertion using WAIT Signal)

## 9.5.4 CSn Assert Period Expansion

The number of cycles from  $\overline{CSn}$  assertion to  $\overline{RD}$ ,  $\overline{WEn}$  assertion can be specified by setting bits SW1 and SW0 in CSnWCR. The number of cycles from  $\overline{RD}$ ,  $\overline{WEn}$  negation to  $\overline{CSn}$  negation can be specified by setting bits HW1 and HW0. Therefore, a flexible interface to an external device can be obtained. Figure 9.10 shows an example. A Th cycle and a Tf cycle are added before and after an ordinary cycle, respectively. In these cycles,  $\overline{RD}$  and  $\overline{WEn}$  are not asserted, while other signals are asserted. The data output is prolonged to the Tf cycle, and this prolongation is useful for devices with slow writing operations.

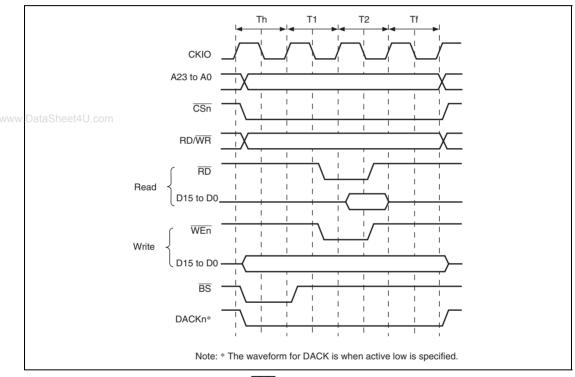

Figure 9.10 CSn Assert Period Expansion

#### 9.5.5 SDRAM Interface

**SDRAM Direct Connection:** The SDRAM that can be connected to this LSI is a product that has 11/12/13 bits of row address, 8/9/10 bits of column address, 4 or less banks, and uses the A10 pin for setting precharge mode in read and write command cycles. The control signals for direct connection of SDRAM are  $\overline{RAS}$ ,  $\overline{CAS}$ ,  $\overline{RD/WR}$ , DQM1, DQM0, CKEand  $\overline{CS3}$ . All the signals other than  $\overline{CS3}$  are common to all areas, and signals other than CKE are valid when  $\overline{CS3}$  is asserted. The data bus width of the area that is connected to SDRAM should be set to 16 bits.

Burst read/single write (burst length 1) and burst read/burst write (burst length 1) are supported as the SDRAM operating mode.

Commands for SDRAM can be specified by  $\overline{RAS}$ ,  $\overline{CAS}$ ,  $\overline{RD/WR}$ , and specific address signals. These commands are shown below.

- NOP
- Auto-refresh (REF)
- Self-refresh (SELF)
- All banks pre-charge (PALL)
- Specified bank pre-charge (PRE)
- Bank active (ACTV)
- Read (READ)
- Read with pre-charge (READA)
- Write (WRIT)
- Write with pre-charge (WRITA)
- Write mode register (MRS)

The byte to be accessed is specified by DQM1 and DQM0. Reading or writing is performed for a byte whose corresponding DQMn is low. For details on the relationship between DQMn and the byte to be accessed, refer to section 9.5.1, Endian/Access Size and Data Alignment.

Figures 9.11 shows as example of the connection of the SDRAM with this LSI. Address area of this LSI is allocated in byte units. Therefore, note that bit addresses of an external memory and those of this LSI differ when handling data in longword units or word units.

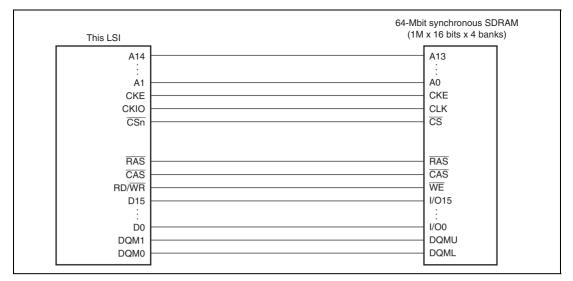

Figure 9.11 Example of 16-Bit Data-Width SDRAM Connection

w.DataSheet4U.com

Address Multiplexing: An address multiplexing is specified so that SDRAM can be connected without external multiplexing circuitry according to the setting of bits BSZ[1:0] in CS3BCR, AxROW[1:0] and AxCOL[1:0] in SDCR. Tables 9.7 to 9.9 show the relationship between the settings of bits BSZ[1:0], A3ROW[1:0], and A3COL[1:0] and the bits output at the address pins. Do not specify those bits in the manner other than this table, otherwise the operation of this LSI is not guaranteed. A23 to A18 are not multiplexed and the original values of address are always output at these pins.

When the data bus width is 16 bits (BSZ[1:0] =B'10), A0 of SDRAM specifies a word address. Therefore, connect this A0 pin of SDRAM to the A1 pin of the LSI; the A1 pin of SDRAM to the A2 pin of the LSI, and so on.

Notes: 1. L/H is a bit used in the command specification; it is fixed at L or H according to the access mode.

<sup>2.</sup> Bank address specification

**Burst Read:** A burst read occurs in the following cases with this LSI.

- Access size in reading is larger than data bus width.
- 16-byte transfer in cache miss.
- 16-byte transfer in DMAC (access to non-cacheable region)

This LSI always accesses the SDRAM with burst length 1. For example, read access of burst length 1 is performed consecutively 8 times to read 16-byte continuous data from the SDRAM that is connected to a 16-bit data bus.

Table 9.10 shows the relationship between the access size and the number of bursts.

Table 9.10 Relationship between Access Size and Number of Bursts

Data Bus Width	Access Size	Number of Bursts
16 bits	8 bits	1
	16 bits	1
DataSheet4U.com	32 bits	2
	16 bits	8

Figures 9.12 and 9.13 show a timing chart in burst read. In burst read, an ACTV command is output in the Tr cycle, the READA command is issued in the Tc1 to Tc7 cycles, the READA command is issued in the Tc8 cycle, and the read data is received at the rising edge of the external clock (CKIO) in the Td1 to Td8 cycles. The Tap cycle is used to wait for the completion of an auto-precharge induced by the READ command in the SDRAM. In the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Tap cycles is specified by the TRP1 and TRP0 bits of the CS3WCR register.

In this LSI, wait cycles can be inserted by specifying each bit in the CS3WCR register to connect the SDRAM in variable frequencies. Figure 9.13 shows an example in which wait cycles are inserted. The number of cycles from the Tr cycle where the ACTV command is output to the Tc1 cycle where the READA command is output can be specified using the TRCD1 and TRCD0 bits of the CS3WCR register. If the TRCD1 and TRCD0 bits specify two cycles or more, a Trw cycle where the NOT command is issued is inserted between the Tr cycle and Tc1 cycle. The number of cycles from the Tc1 cycle where the READA command is output to the Td1 cycle where the read data is latched can be specified using the A3CL1 and A3CL0 bits of the CS3WCR register. The number of cycles from Tc1 to Td1 corresponds to the synchronous DRAM CAS latency. The CAS latency for the synchronous DRAM is normally defined as up to three cycles. However, the CAS latency in this LSI can be specified as 1 to 4 cycles. This CAS latency can be achieved by connecting a latch circuit between this LSI and the synchronous DRAM.

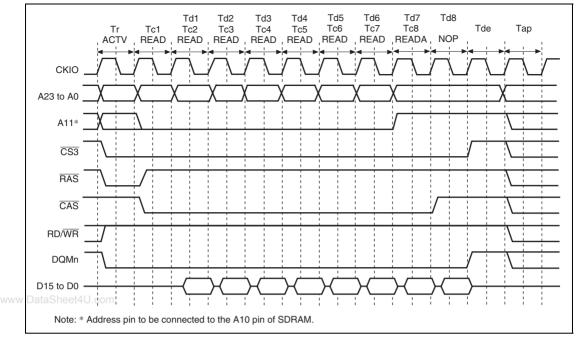

Figure 9.12 Burst Read Basic Timing (Auto Pre-charge)

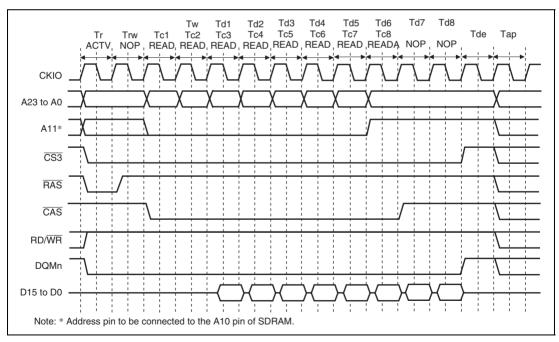

Figure 9.13 Burst Read Wait Specification Timing (Auto Pre-charge)

**Single Read:** A read access ends in one cycle when data exists in non-cacheable region and the data bus width is larger than or equal to access size. As the burst length is set to 1 in synchronous SDRAM burst read/single write mode, only the required data is output. Consequently, no unnecessary bus cycles are generated even when a cache-through area is accessed.

Figure 9.14 shows the single read basic timing.

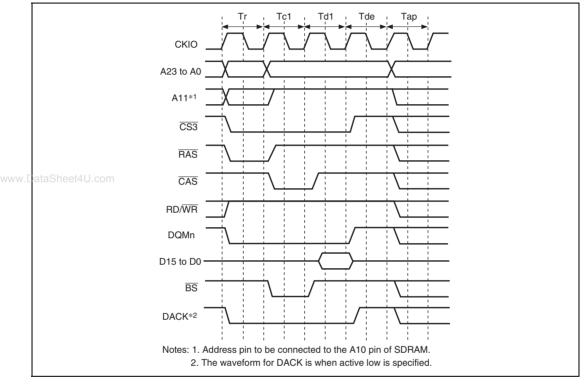

Figure 9.14 Single Read Wait Specification Timing (Auto Pre-charge)

**Burst Write:** A burst write occurs in the following cases in this LSI.

- Access size in writing is larger than data bus width.
- Copyback of the cache
- 16-byte transfer in DMAC (access to non-cacheable region)

This LSI always accesses SDRAM with burst length 1. For example, write access of burst length 1 is performed continuously 8 times to write 16-byte continuous data to the SDRAM that is connected to a 16-bit data bus.

The relationship between the access size and the number of bursts is shown in table 9.10.

Figure 9.15 shows a timing chart for burst writes. In burst write, an ACTV command is output in the Tr cycle, the WRIT command is issued in the Tc1 to Tc7 cycles, and the WRITA command is issued to execute an auto-precharge in the Tc8 cycle. In the write cycle, the write data is output simultaneously with the write command. After the write command with the auto-precharge is output, the Trw1 cycle that waits for the auto-precharge initiation is followed by the Tap cycle that waits for completion of the auto-precharge induced by the WRITA command in the SDRAM. In the Tap cycle, a new command will not be issued to the same bank. However, access to another CSn space or another bank in the same SDRAM space is enabled. The number of Trw1 cycles is specified by the TRWL1 and TRWL0 bits of the CS3WCR register. The number of Tap cycles is specified by the TRP1 and TRP0 bits of the CS3WCR register.

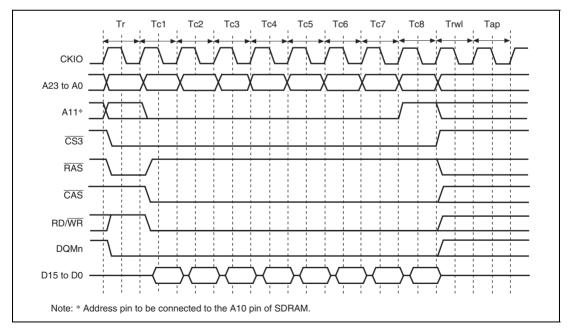

Figure 9.15 Basic Timing for Synchronous DRAM Burst Write (Auto Pre-charge)

www.DataSheet4U.com

**Single Write:** A write access ends in one cycle when data is written in non-cacheable region and the data bus width is larger than or equal to access size. This is called single write.

Figure 9.16 shows the single write basic timing.

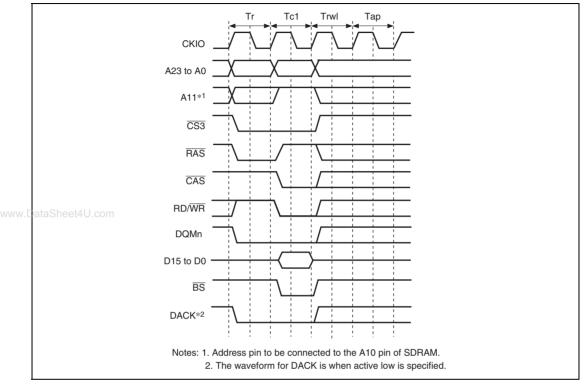

Figure 9.16 Single Write Basic Timing (Auto-Precharge)

Bank Active: The synchronous DRAM bank function is used to support high-speed accesses to the same row address. When the BACTV bit in SDCR is 1, accesses are performed using commands without auto-precharge (READ or WRIT). This function is called bank-active function. When the bank-active function is used, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command. As synchronous DRAM is internally divided into several banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued. The number of cycles between issuance of the PRE command and the ACTV command is determined by the TRP[1:0] bits in CS3WCR.

In a write, when an auto-precharge is performed, a command cannot be issued to the same bank for a period of Trwl + Tap cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by Trwl + Tap cycles for each write.

There is a limit on tRAS, the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of tRAS.

A burst read cycle without auto-precharge is shown in figure 9.17, a burst read cycle for the same row address in figure 9.18, and a burst read cycle for different row addresses in figure 9.19. Similarly, a single write cycle without auto-precharge is shown in figure 9.260, a single write cycle for the same row address in figure 9.21, and a single write cycle for different row addresses in figure 9.22.

In figure 9.18, a Tnop cycle in which no operation is performed is inserted before the Tc cycle that issues the READ command. The Tnop cycle is inserted to acquire two cycles of latency for the DQMn signal that specifies the read byte in the data read from the SDRAM. If the CAS latency is specified as two cycles or more, the Tnop cycle is not inserted because the two cycles of latency can be acquired even if the DQMn signal is asserted after the Tc cycle.

When bank active mode is set, if only accesses to the respective banks in area with the bank-active function set are considered, as long as accesses to the same row address continue, the operation starts with the cycle in figure 9.17 or 9.20, followed by repetition of the cycle in figure 9.18 or 9.21. An access to a different area during this time has no effect. If there is an access to a different row address in the bank active state, after this is detected the bus cycle in figure 9.19 or 9.22 is executed instead of that in figure 9.18 or 9.21. In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration.

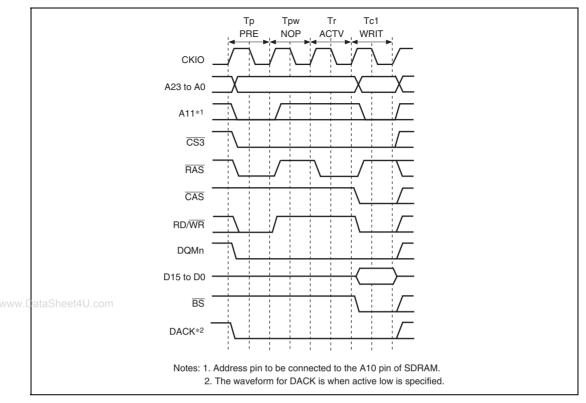

Figure 9.22 Single Write Timing (Bank Active, Different Row Addresses)

**Refreshing:** This LSI has a function for controlling synchronous DRAM refreshing. Autorefreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in SDCR. A continuous refreshing can be performed by setting the RRC[2:0] bits in RTCSR. If SDRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

# 1. Auto-refreshing

Refreshing is performed at intervals determined by the input clock selected by bits CKS[2:0] in RTCSR, and the value set by in RTCOR. The each register should be set so as to satisfy the refresh interval stipulation for the SDRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in SDCR, then make the CKS[2:0] and RRC[2:0] in RTCSR settings. When the clock is selected by bits CKS[2:0], RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed for the number of times specified by the RRC[2:0]. At the same time, RTCNT is cleared to zero and the count-up is restarted. Figure 9.23 shows the auto-refresh cycle timing.

After starting, the auto refreshing, PALL command is issued in the Tp cycle to make all the banks to pre-charged state from active state after waiting for the completion when some bank is being pre-charged. Then REF command is issued in the Trr cycle after inserting idle cycles of which number is specified by the TRP[1:0] bits in CS3WCR. A new command is not issued for the duration of the number of cycles specified by the TRC[1:0] bits in CS3WCR after the Trr cycle. The TRC[1:0] bits must be set so as to satisfy the SDRAM refreshing cycle time stipulation (tRC). A NOP cycle is inserted between the Tp cycle and Trr cycle when the setting value of the TRP[1:0] bits in CS3WCR is longer than or equal to 2 cycles.

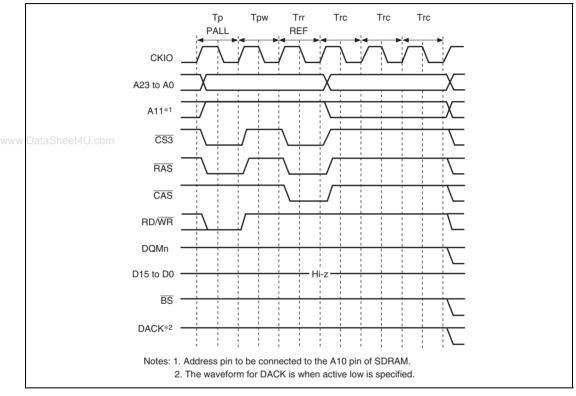

Figure 9.23 Auto-Refresh Timing

# 2. Self-refreshing

Self-refresh mode in which the refresh timing and refresh addresses are generated within the SDRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit in SDCR to 1. After starting the self-refreshing, PALL command is issued in Tp cycle after the completion of the pre-charging bank. A SELF command is then issued after inserting idle cycles of which number is specified by the TRP[1:0] bits in CS3WSR. The SDRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the TRC[1:0] bits in CS3WCR.

www.DataSheet4U.com

Self-refresh timing is shown in figure 9.24. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, or when exiting standby mode other than through a power-on reset, auto-refreshing is restarted if the RFSH bit is set to 1 and the RMODE bit is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately.

After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the LSI standby function, and is maintained even after recovery from standby mode other than through a power-on reset. In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared.

After self-refreshing has been cleared, CKE should be high for a specified time for the SDRAM. When the SDRAM is in power-down mode (PDOWN in SDCR is set to 1), transition to self-refresh mode should be made after clearing power-down mode.

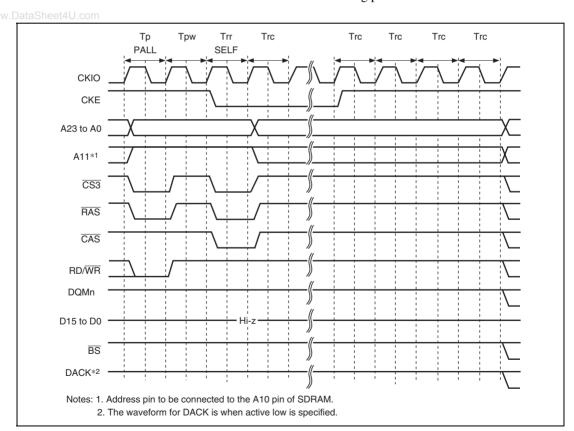

Figure 9.24 Self-Refresh Timing

Relationship between Refresh Requests and Bus Cycles: If a refresh request occurs during bus cycle execution, the refresh cycle must wait for the bus cycle to be completed. If a refresh request occurs while the bus is released by the bus arbitration function, the refresh will not be executed until the bus mastership is acquired. This LSI supports requests by the  $\overline{\text{REFOUT}}$  pin for the bus mastership while waiting for the refresh request. The  $\overline{\text{REFOUT}}$  pin is asserted low until the bus mastership is acquired.

If a new refresh request occurs while waiting for the previous refresh request, the previous refresh request is deleted. To refresh correctly, a bus cycle longer than the refresh interval or the bus mastership occupation must be prevented from occurring. If a bus mastership is requested during self-refresh, the bus will not be released until the refresh is completed.

www.DataSheet4LLcon

**Low-Frequency Mode:** When the SLOW bit in SDCR is set to 1, output of commands, addresses, and write data, and fetch of read data are performed at a timing suitable for operating SDRAM at a low frequency.

Figure 9.25 shows the access timing in low-frequency mode. In this mode, commands, addresses, and write data are output in synchronization with the falling edge of CKIO, which is half a cycle delayed than the normal timing. Read data is fetched at the falling edge of CKIO, which is half a cycle faster than the normal timing. This timing allows the hold time of commands, addresses, write data, and read data to be extended.

If SDRAM is operated at a high frequency with the SLOW bit set to 1, the setup time of commands, addresses, write data, and read data are not guaranteed. Take the operating frequency and timing design into consideration when making the SLOW bit setting.

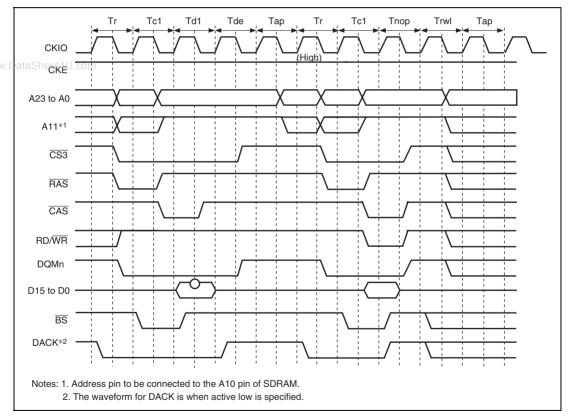

Figure 9.25 Low-Frequency Mode Access Timing

**Power-Down Mode:** If the PDOWN bit of the SDCR register is set to 1, the SDRAM is placed in the power-down mode by bringing the CKE signal to the low level in the non-access cycle. This power-down mode can effectively lower the power consumption in the non-access cycle. However, please note that if an access occurs in power-down mode, a cycle of overhead occurs because a cycle is inserted to assert the CKE signal in order to cancel the power-down mode. After the SDRAM access ends, it is possible to shift to the power down mode again by accessing the memory other than SDRAM (CKE becomes Low level).

Figure 9.26 shows the access timing in power-down mode.

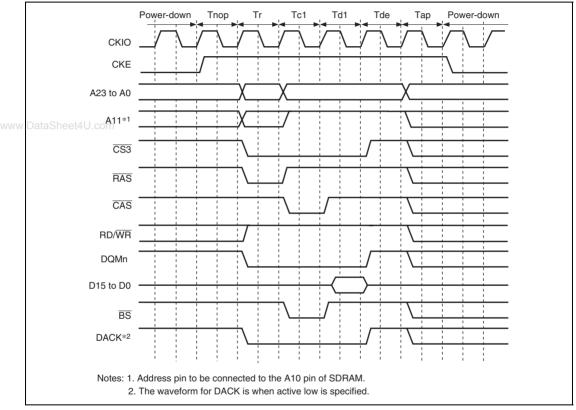

Figure 9.26 Power-Down Mode Access Timing

**Power-On Sequence:** In order to use the SDRAM, mode setting must first be performed after powering on. To perform SDRAM initialization correctly, the bus state controller registers must first be set, followed by a write to the SDRAM mode register by accessing the SDMR3 register. In SDRAM mode register setting, the address signal value at that time is latched by a combination of the  $\overline{CS3}$ ,  $\overline{RAS}$ ,  $\overline{CAS}$ , and  $\overline{RD/WR}$  signals. If the value to be set is X, the bus state controller provides for value X to be written to the SDRAM mode register by performing a write to address H'A4FD5000 + X for SDRAM. In this operation the data is ignored. To set burst read/single write (burst length 1) or burst read/burst write (burst length 1), CAS latency 2 to 3, wrap type = sequential, and burst length 1 supported by the LSI, arbitrary data is written in a word-size access to the addresses shown in table 9.11. In this time 0 is output at the external address pins of A12 or later.

## Table 9.11 Access Address in SDRAM Mode Register Write

Setting for Area 3 (SDMR3)
 Burst read/single write (burst length 1):

Data Bus Width	CAS Latency	Access Address	External Address Pin
16 bits	2	H'A4FD5440	H'0000440
	3	H'A4FD5460	H'0000460

Burst read/burst write (burst length 1):

Data Bus Width	CAS Latency	Access Address	External Address Pin
16 bits	2	H'A4FD5040	H'0000040
	3	H'A4FD5060	H'0000060

Mode register setting timing is shown in figure 9.27. A PALL command (all bank pre-charge command) is firstly issued. A REF command (auto refresh command) is then issued eight times. An MRS command (mode register write command) is finally issued. Idle cycles, of which number is specified by the TRP[1:0] bits in CS3WCR, are inserted between the PALL and the first REF. Idle cycles, of which number is specified by the TRC[1:0]bits in CS3WCR, are inserted between REF and REF, and between the 8th REF and MRS. Idle cycles, of which number is one or more, are inserted between the MRS and a command to be issued next.

It is necessary to keep idle time of certain cycles for SDRAM before issuing PALL command after power-on. Refer the manual of the SDRAM to be used for the idle time to be needed. When the pulse width of the reset signal is longer then the idle time, mode register setting can be started immediately after the reset, but care should be taken when the pulse width of the reset signal is shorter than the idle time.

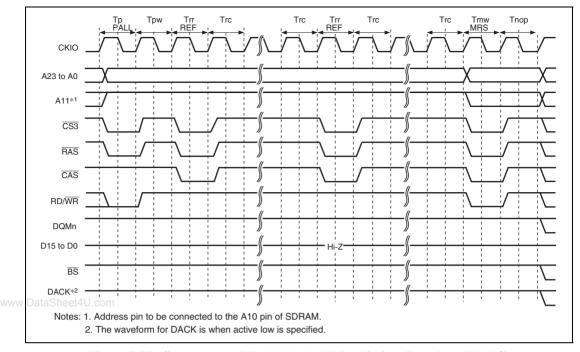

Figure 9.27 Synchronous DRAM Mode Write Timing (Based on JEDEC)

#### 9.5.6 Burst ROM Interface

The burst ROM interface is used to access a memory with a high-speed read function using a method of address switching called the burst mode or page mode. In a burst ROM interface, basically the same access as the normal space interface is performed, but the 2nd and subsequent accesses are performed only by changing the address, without negating the  $\overline{\text{RD}}$  signal at the end of the 1st cycle. In the 2nd and subsequent accesses, addresses are changed at the falling edge of the CKIO signal.

For the 1st access cycle, the number of wait cycles specified by the W[3:0] bits of the CSnWCR register is inserted. For the 2nd and subsequent access cycles, the number of wait cycles specified by the BW[1:0] bits of the CSnWCR register is inserted.

In the access to the burst ROM, the  $\overline{BS}$  signal is asserted only to the first access cycle. An external wait input is valid only to the first access cycle. In the single access or write access that do not perform the burst operation in the page flash ROM interface, access timing is same as a normal space interface. Table 9.12 lists a relationship between bus width, access size, and the number of bursts. Figure 9.28 shows a timing chart.

Table 9.12 Relationship between Data Bus Width, Access Size, and Number of Bursts

Data Bus Width	Access Size	Number of Bursts	Number of Accesses
8 bits	8 bits	1	1
	16 bits	2	1
	32 bits	4	1
	16 bytes	16	1
16 bits	8 bits	1	1
	16 bits	1	1
	32 bits	2	1
	16 bytes	8	1

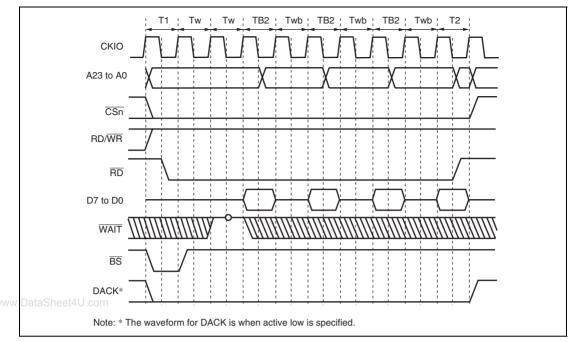

Figure 9.28 Burst ROM Access (Data Bus Width 8 Bits, 4-byte Transfer (number of burst 4), Access Wait for the 1st time 2, Access Wait for 2nd Time and after 1)

### 9.5.7 Byte-Selection SRAM Interface

#### **Basic Access Timing:**

The byte-selection SRAM interface is a memory interface which outputs a byte-selection pin  $(\overline{WE})$  in a read/write bus cycle. This interface has 16-bit data pins and accesses SRAMs having upper and lower byte selection pins, such as UB and LB.

When the BAS bit of the CSnWCR register is cleared to 0 (initial value), the write access timing of the byte-selection SRAM interface is the same as that for the normal space interface. While in read access of a byte-selection SRAM interface, the byte-selection signal is output from the  $\overline{WEn}$  pin, which is different from that for the normal space interface. The basic access timing is shown in figure 9.29. In write access, data is written to the memory according to the timing of the byte-selection pin ( $\overline{WEn}$ ). For details, please refer to the Data Sheet for the corresponding memory.

If the BAS bit of the CSnWCR register is set to 1, the WEn pin and RD/WR pin timings change. Figure 9.30 shows the basic access timing. In write access, data is written to the memory according to the timing of the write enable pin (RD/WR). The data hold timing from RD/WR negation to data write must be acquired by setting the HW[1:0] bits of the CSnWCR register. Figure 9.31 shows an example of Connection with Byte-Selection SRAM.

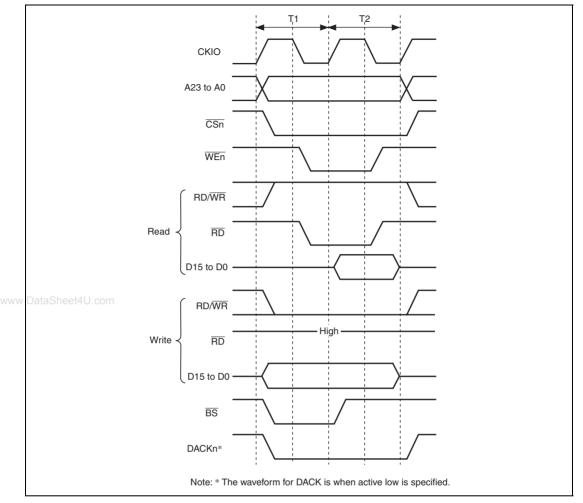

Figure 9.29 Byte-Selection SRAM Basic Access Timing (BAS = 0)

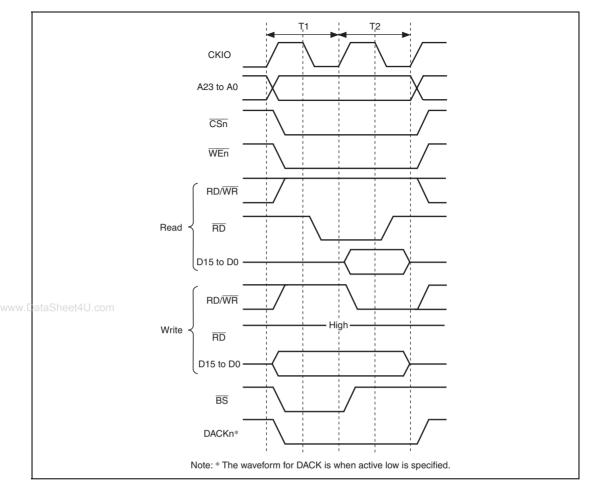

Figure 9.30 Byte-Selection RAM Basic Access Timing (BAS = 1)

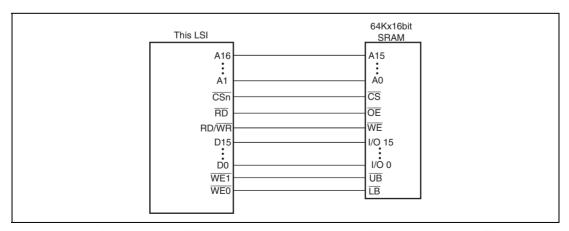

Figure 9.31 Example of Connection with 16-Bit Data-Width Byte-Selection SRAM www.DataSheet4U.com

#### **Byte-Selection SRAM Interface Restrictions:**

The BAS bit should not be set to 1 for the byte-selection SRAM while the SDRAM in auto-refresh is used. If the BAS bit is set to 1, a refresh cannot be issued.

#### Problems:

When the byte-selection SRAM is accessed (BAS = 1) before a refresh is carried out, the ACTV command is issued instead of the  $RD/\overline{WR}$  low output during the PALL command cycle. Therefore, the operation of SDRAM cannot be guaranteed in subsequent REF command.

#### Avoidance measures:

- 1. A pseudo SRAM which is mixed with SDRAM should support UB and LB control write.
- 2. When the WE pin of MCP is necessary to be connected to the RD/WR pin of this LSI to use MCP incorporating a flash memory, make access according to the following procedure.

Make SDRAM enter in self-refresh

Set the functions of CSnBCR and CSnWCR in the flash memory area for using the byte-selection SRAM (BAS = 1): accessing byte-selection SRAM and WE write control.

Start write access to a flash memory

When a write access to a flash memory ends, set the UB and LB control (BAS = 0) and then clear the self-refresh function.

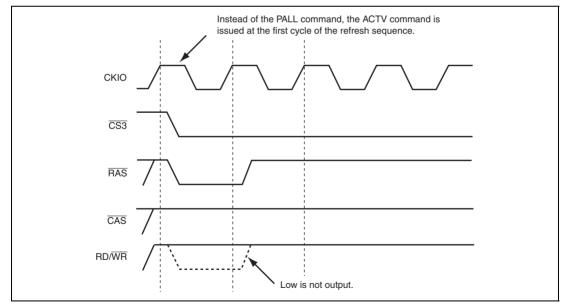

Figure 9.32 Waveform in the Event of a Problem

#### 9.5.8 Wait between Access Cycles

As the operating frequency of LSIs becomes higher, the off-operation of the data buffer often collides with the next data access when the read operation from devices with slow access speed is completed. As a result of these collisions, the reliability of the device is low and malfunctions may occur. A function that avoids data collisions by inserting wait cycles between continuous access cycles has been newly added.

The number of wait cycles between access cycles can be set by bits IWW[1:0], IWRWD[1:0], IWRWS[1:0], IWRRD[1:0], and IWRRS[1:0] in the CSnBCR register, and bits DMAIW[1:0] and DMAIWA in CMNCR. The conditions for setting the wait cycles between access cycles (idle cycles) are shown below.

- 1. Continuous accesses are write-read or write-write
- 2. Continuous accesses are read-write for different spaces
- 3. Continuous accesses are read-write for the same space
- 4. Continuous accesses are read-read for different spaces
- 5. Continuous accesses are read-read for the same space
- 6. Data output from an external device caused by DMA single transfer is followed by data output from another device that includes this LSI (DMAIWA = 0)
- 7. Data output from an external device caused by DMA single transfer is followed by any type of access (DMAIWA = 1)

#### 9.5.9 Bus Arbitration

In bus arbitration, the LSI operates in two ways;

- 1. The LSI has the bus mastership in the normal state, and releases the bus mastership after receiving a bus request from another device.
- 2. The LSI does not have the bus mastership in the normal state; it requests the bus mastership each time that external access is necessary.

In the case of the LSI with bus mastership in the normal state, this is called master mode. This LSI supports master mode.

To prevent device malfunction while the bus mastership is transferred between master and slave, the LSI negates all of the bus control signals before bus release. When the bus mastership is received, all of the bus control signals are first negated and then driven appropriately. In this case, output buffer contention can be prevented because the master and slave drive the same signals with the same values. In addition, to prevent noise while the bus control signal is in the high impedance state, pull-up resistors must be connected to these control signals.

Bus mastership is transferred at the boundary of bus cycles. Namely, bus mastership is released immediately after receiving a bus request when a bus cycle is not being particulated Sheet-leason of the cycle is not being particulated.

bus mastership is delayed until the bus cycle is complete when a bus cycle is in progress. Even when from outside the LSI it looks like a bus cycle is not being performed, a bus cycle may be performing internally, started by inserting wait cycles between access cycles. Therefore, it cannot be immediately determined whether or not bus mastership has been released by looking at the  $\overline{\text{CSn}}$  signal or other bus control signals. The states that do not allow bus mastership release are shown below.

- 1. 16-byte transfer because of a cache miss
- 2. During copyback operation for the cache
- 3. Between the read and write cycles of a TAS instruction
- 4. Multiple bus cycles generated when the data bus width is smaller than the access size (for example, between bus cycles when longword access is made to a memory with a data bus width of 8 bits)
- 5. 16-byte transfer by the DMAC

The bus release by the  $\overline{BREQ}$  and  $\overline{BACK}$  signal handshaking requires some overhead. If the slave has many tasks, multiple bus cycles should be executed in a bus mastership acquisition. Reducing the cycles required for master to slave bus mastership transitions streamlines the system design.

**Master Mode:** In master mode, the LSI has the bus mastership until a bus request is received from another device. Upon acknowledging the assertion (low level) of the external bus request signal  $\overline{BREQ}$ , the LSI releases the bus at the completion of the current bus cycle and asserts the  $\overline{BACK}$  signal. After the LSI acknowledges the negation (high level) of the  $\overline{BREQ}$  signal that indicates the slave has released the bus, it negates the  $\overline{BACK}$  signal and resumes the bus usage.

The SDRAM issues all bank pre-charge commands (PALLs) when active banks exist and releases the bus after completion of a PALL command.

The bus sequence is as follows.

- 1. The address bus and data bus are placed in a high-impedance state synchronized with the rising edge of CKIO.
- 2. The bus mastership enable signal is asserted 0.5 cycles after the above timing, synchronized with the falling edge of CKIO.
- 3. The bus control signals (BS, CSn, RAS, CAS, WEn/DQMn, RD, and RD/WR) are placed in the high-impedance state at subsequent rising edges of CKIO. These bus control signals go high one cycle before being placed in the high-impedance state.
- 4. Bus request signals are sampled at the falling edge of CKIO.

The sequence for reclaiming the bus mastership from a slave is described below.

- 1. 1.5 cycles after the negation of BREQ is detected at the falling edge of CKIO, the bus control signals are driven high.
- 2. The bus enable signal is negated at the next falling edge of the clock. The address bus and data bus are started to be driven at the next rising edge of CKIO.
- 3. The fastest timing at which actual bus cycles can be resumed after bus control signal assertion is at the rising edge of the CKIO where address and data signals are driven.

Figure 9.33 shows the bus arbitration timing in master mode.

In an original slave device designed by the user, multiple bus accesses are generated continuously to reduce the overhead caused by bus arbitration. In this case, to execute SDRAM refresh correctly, the slave device must be designed to release the bus mastership within the refresh interval time. To achieve this, the LSI instructs the  $\overline{\text{REFOUT}}$  pin to request the bus mastership while the SDRAM waits for the refresh. The LSI asserts the  $\overline{\text{REFOUT}}$  pin until the bus mastership is received. If the slave releases the bus, the LSI acquires the bus mastership to execute the SDRAM refresh.

has many tasks, multiple bus cycles should be executed in a bus mastership acquisition. Reducing the cycles required for master to slave bus mastership transitions streamlines the system design.

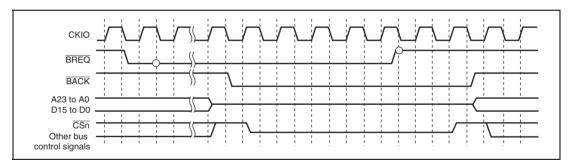

Figure 9.33 Bus Arbitration Timing (Master Mode)

**Master and Slave Cooperation:** Figure 9.34 shows an example of the master and slave devices. To control system resources correctly between master and slave devices, the roles of the master and slave devices must be defined appropriately. The SDRAM must be initialized before using the devices. To use the standby operation to reduce power consumption, the roles of the master and slave devices must also be defined appropriately.

This LSI is designed to execute all controls such as initialization, refresh, and standby in a device in master mode. If a master device and a slave device are connected directly in a two-processor configuration, the master device performs all processing other than memory access. In this case, the slave device must not access devices such as an SDRAM that require initialization prior to device initialization. The following methods can be used to prevent this.

- 1. An external circuit can be connected that releases the slave device reset by the master device.
- 2. The master can set a flag to the devices such as an SRAM that does not require initialization after initialization and the slave initiates access after checking to see that the flag has been set.
- 3. An external circuit can be connected to generate an interrupt from the master device to a slave device after initialization. The slave is released from the wait state by the interrupt.

If self-refresh mode is specified for the SDRAM, the master device does not release the bus. If a transition is underway to standby mode, or if the master clock stops because of a frequency change, the master device cannot release the bus. To prevent the slave from issuing bus requests in a case such as this, the slave must be put into the sleep state.

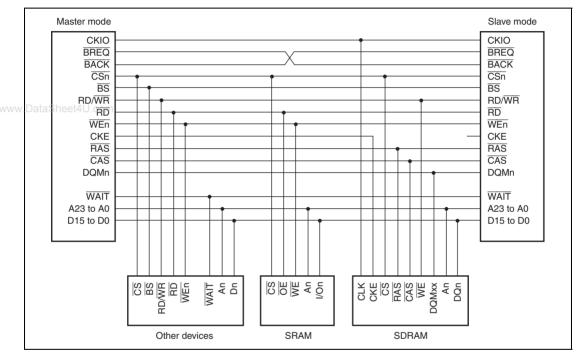

Figure 9.34 Master and Slave Connection Example

#### 9.5.10 Usage Notes

**Reset:** The bus state controller (BSC) can be initialized completely only at power-on reset. At power-on reset, all signals are negated and output buffers are turned off regardless of the bus cycle state. All control registers are initialized.

In standby, sleep, and manual reset, control registers of the bus state controller are not initialized. At manual reset, the current bus cycle being executed is completed and then the access wait state is entered. If a 16-byte transfer is performed by a cache or if another LSI on-chip bus master module is executed when a manual reset occurs, the current access is cancelled in longword units because the access request is cancelled by the bus master at manual reset. If a manual reset is requested during cache fill operations, the contents of the cache cannot be guaranteed. Since the RTCNT continues counting up during manual reset signal assertion, a refresh request occurs to initiate the refresh cycle. In addition, a bus arbitration request by the BREQ signal can be accepted during manual reset signal assertion.

Some flash memories may specify a minimum time from reset release to the first access. To ensure this minimum time, the bus state controller supports a 7-bit counter (RWTCNT). At power-on reset, the RWTCNT is cleared to 0. After power-on reset, RWTCNT is counted up synchronously together with CKIO and an external access will not be generated until RWTCNT is counted up to H'007F. At manual reset, RWTCNT is not cleared.

Access from the Site of the LSI Internal Bus Master: There are three types of LSI internal buses: a cache bus (L bus), internal bus (I bus), and peripheral bus. The CPU and cache memory are connected to the cache bus. Internal bus masters other than the CPU and bus state controller are connected to the internal bus. Low-speed peripheral modules are connected to the peripheral bus. Internal memories other than the cache memory and debugging modules such as a UBC and AUD are connected bidirectionally to the cache bus and internal bus. Access from the cache bus to the internal bus is enabled but access from the internal bus to the cache bus is disabled. This gives rise to the following problems.

On-chip bus masters such as DMAC other than the CPU can access internal memory other than the cache memory but cannot access the cache memory. If an on-chip bus master other than the CPU writes data to an external memory other than the cache, the contents of the external memory may differ from that of the cache memory. To prevent this problem, if the external memory whose contents is cached is written by an on-chip bus master other than the CPU, the corresponding cache memory should be purged by software.

If the CPU initiates read access for the cache, the cache is searched. If the cache stores data, the CPU latches the data and completes the read access. If the cache does not store data, the CPU performs four contiguous longword read cycles to perform cache fill operations via the internal bus. If a cache miss occurs in byte or word operand access or at a branch to an odd word boundary (4n + 2), the CPU performs four contiguous longword accesses to perform a cache fill operation on the external interface. For a cache-through area, the CPU performs accessed the complete t

actual access addresses. For an instruction fetch to an even word boundary (4n), the CPU performs longword access. For an instruction fetch to an odd word boundary (4n + 2), the CPU performs word access.

For a read cycle of a cache-through area or an on-chip peripheral module, the read cycle is first accepted and then read cycle is initiated. The read data is sent to the CPU via the cache bus.

In a write cycle for the cache area, the write cycle operation differs according to the cache write methods.

In write-back mode, the cache is first searched. If data is detected at the address corresponding to the cache, the data is then re-written to the cache. In the actual memory, data will not be re-written until data in the corresponding address is re-written. If data is not detected at the address corresponding to the cache, the cache is modified. In this case, data to be modified is first saved to the internal buffer, 16-byte data including the data corresponding to the address is then read, and data in the corresponding access of the cache is finally modified. Following these operations, a write-back cycle for the saved 16-byte data is executed.

v DataSheet4U.com

In write-through mode, the cache is first searched. If data is detected at the address corresponding to the cache, the data is re-written to the cache simultaneously with the actual write via the internal bus. If data is not detected at the address corresponding to the cache, the cache is not modified but an actual write is performed via the internal bus.

Since the bus state controller (BSC) incorporates a one-stage write buffer, the BSC can execute an access via the internal bus before the previous external bus cycle is completed in a write cycle. If the on-chip module is read or written after the external low-speed memory is written, the on-chip module can be accessed before the completion of the external low-speed memory write cycle. In read cycles, the CPU is placed in the wait state until read operation has been completed. To continue the process after the data write to the device has been completed, perform a dummy read to the same address to check for completion of the write before the next process to be executed.

The write buffer of the BSC functions in the same way for an access by a bus master other than the CPU such as the DMAC. Accordingly, to perform dual address DMA transfers, the next read cycle is initiated before the previous write cycle is completed. Note, however, that if both the DMA source and destination addresses exist in external memory space, the next write cycle will not be initiated until the previous write cycle is completed.

On-Chip Peripheral Module Access: To access an on-chip module register, two or more peripheral module clock ( $P\phi$ ) cycles are required. Care must be taken in system design.

# Section 10 Direct Memory Access Controller (DMAC)

This LSI includes the direct memory access controller (DMAC).

The DMAC can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

## 10.1 Features

- Four channels (One channel can receive an external request)
  Channel 0 can receive an external request.
- 4-GB physical address space
- Data transfer unit is selectable: Byte, Word (two bytes), Longword (four bytes), and 16 Bytes (longword × 4)
- Maximum transfer count: 16777216 transfers (24 bits)
- Address mode: Dual address mode and single address mode are supported.
- Transfer requests
  - External request
  - On-chip peripheral module request
  - Auto request

The following modules can issue an on-chip peripheral module request.

- SCIF0, SCIF1, SIOF, and USBF
- Selectable bus modes
  - Cycle steal mode (normal mode and intermittent mode)
  - Burst mode
- Selectable channel priority levels: The channel priority levels are selectable between fixed mode and round-robin mode.
- Interrupt request: An interrupt request can be generated to the CPU at the end of the specified counts of data transfer.
- External request detection: There are following four types of DREQ input detection.
  - Low level detection
  - High level detection
  - Rising edge level detection
  - Falling edge level detection
- Transfer request acknowledge and transfer end signals: Active levels for DACK and TEND can be set independently.

Figure 10.1 shows the block diagram of the DMAC.

# 10.2 Input/Output Pins

Table 10.1 lists the pin configuration of DMAC.

**Table 10.1 Pin Configuration** 

Channel	Pin Name	1/0	Function
0	DREQ	Input	DMA transfer request
			DMA transfer request input from external device to channel 0
	DACK	Output	DMA transfer request acknowledge
			Strobe output to an external I/O at DMA transfer request from external device to channel 0
	TEND	Output	DMA transfer end
			DMA transfer end output for channel 0

www.DataSheet4U.com

## 10.3 Register Descriptions

Register configuration of DMAC is described below. See section 27, List of Registers, for the addresses of these registers and the state of them in each processing status. In the following description of registers for each channel, for example, SAR for channel 0 is described as SAR\_0.

#### Channel 0:

- DMA source address register\_0 (SAR\_0)
- DMA destination address register 0 (DAR 0)
- DMA transfer count register\_0 (DMATCR\_0)
- DMA channel control register\_0 (CHCR\_0)
- DMA initial address register 0 (IAR 0)

#### Channel 1:

- DMA source address register\_1 (SAR\_1)
- DMA destination address register 1 (DAR 1)
- DMA transfer count register 1 (DMATCR 1)
- DMA channel control register \_1 (CHCR\_1)
- DMA initial address register 1 (IAR 1)

#### Channel 2:

- DMA source address register\_2 (SAR\_2)
- DMA destination address register\_2 (DAR\_2)
- DMA transfer count register\_2 (DMATCR\_2)
- DMA channel control register\_2 (CHCR\_2)
- DMA initial address register\_2 (IAR\_2)

#### Channel 3:

- DMA source address register\_3 (SAR\_3)
- DMA destination address register\_3 (DAR\_3)
- DMA transfer count register\_3 (DMATCR\_3)
- DMA channel control register\_3 (CHCR\_3)
- DMA initial address register\_3 (IAR\_3)

#### Common:

- DMA operation register (DMAOR)
- DMA extension resource selector 0 (DMARS0)
- DMA extension resource selector 1 (DMARS1)

## 10.3.1 DMA Source Address Register (SAR)

SAR is a 32-bit readable/writable register that specifies the source address of a DMA transfer. During a DMA transfer, this register indicates the next source address. When the data of an external device with DACK is transferred in the single address mode, the SAR is ignored.

To transfer data in 16 bits or in 32 bits, specify the address with 16-bit or 32-bit address boundary. When transferring data in 16-byte units, a 16-byte boundary (address 16n) must be set for the source address value. The SAR is undefined at reset and retains the current value in standby or module standby mode.

ww.DataSheet4U.com

## 10.3.2 DMA Destination Address Register (DAR)

DAR is a 32-bit readable/writable register that specifies the destination address of a DMA transfer. This register includes count functions, and during a DMA transfer, this register indicates the next destination address. When the data of an external device with DACK is transferred in the single address mode, the DAR is ignored.

To transfer data in 16 bits or in 32 bits, specify the address with 16-bit or 32-bit address boundary. When transferring data in 16-byte units, a 16-byte boundary (address 16n) must be set for the source address value. The DAR is undefined at reset and retains the current value in standby or module standby mode.

## 10.3.3 DMA Transfer Count Register (DMATCR)

DMATCR is a 32-bit readable/writable register that specifies the DMA transfer count (bytes, words, or longwords). The number of transfers is 1 when the setting is H'00000001, 16777215 when H'00FFFFFF is set, and 16777216 (the maximum) when H'000000000 is set. During a DMA transfer, this register indicates the remaining transfer count.

The upper eight bits of DMATCR will return 0 if read, and should only be written with 0. To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one. The DMATCR is undefined at reset and retains the current value in standby or module standby mode.

## 10.3.4 DMA Channel Control Register (CHCR)

CHCR is 32-bit readable/writable register that controls the DMA transfer mode. The CHCR is initialized at reset and retains the current value in the standby or module standby mode.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 27	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
26	RPT	0	R	Repeat Mode
				This bit specifies whether the DMA transfer is carried out in repeat mode or normal mode.
				0: DMA transfer is carried out in normal mode
				1: DMA transfer is carried out in repeat mode
D <mark>25</mark> Sheet4l	RAS	0	R	Repeat Space Set
				This bit sets repeat space as transfer source or transfer destination
				0: Repeat area is transfer destination
				1: Repeat area is transfer source
24	DA	0	R	DMA Asynchronous
				This bit specifies whether the DREQ signal is synchronous signal or asynchronous signal
				This bit is valid only in CHCR_0. In CHCR_1 to CHCR_3, this bit is reserved. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
				0: DREQ is an asynchronous signal
				1: DREQ is a synchronous signal
23	DO	0	R/W	DMA Overrun
				This bit selects whether DREQ is detected by overrun 0 or by overrun 1. This bit is valid only in CHCR_0. This bit is reserved in CHCR_1 to CHCR_3. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
				0: Detects DREQ by overrun 0
				1: Detects DREQ by overrun 1

Bit	Bit Name	Initial Value	R/W	Descriptions
22	TL	0	R/W	Transfer End Level
				This bit specifies the TEND signal output is high active or low active. This bit is valid only in CHCR_0. This bit is reserved in CHCR_1 to CHCR_3. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
				0: Low-active output of TEND
				1: High-active output of TEND
21 to 18	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
17	AM	0	R/W	Acknowledge Mode
				AM specifies whether DACK is output in data read cycle or in data write cycle in dual address mode.
				In single address mode, DACK is always output regardless of the specification by this bit.
				This bit is valid only in CHCR_0. This bit is reserved in CHCR_1 to CHCR_3. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
				0: DACK output in read cycle (Dual address mode)
				1: DACK output in write cycle (Dual address mode)
16	AL	0	R/W	Acknowledge Level
				AL specifies the DACK (acknowledge) signal output is high active or low active.
				This bit is valid only in CHCR_0. This bit is reserved in CHCR_1 to CHCR_3. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
				0: Low-active output of DACK
				1: High-active output of DACK

Bit	Bit Name	Initial Value	R/W	Descriptions
15	DM1	0	R/W	Destination Address Mode
14	DM0	0	R/W	DM1 and DM0 select whether the DMA destination address is incremented, decremented, or left fixed. (In single address mode, DM1 and DM0 bits are ignored when data is transferred to an external device with DACK.)
				00: Fixed destination address (setting prohibited in 16-byte transfer)
				01: Destination address is incremented (+1 in 8-bit transfer, +2 in 16-bit transfer, +4 in 32-bit transfer, +16 in 16-byte transfer)
				<ol> <li>Destination address is decremented (-1 in 8-bit transfer, -2 in 16-bit transfer, -4 in 32-bit transfer; illegal setting in 16-byte transfer)</li> </ol>
				11: Reserved (setting prohibited)
13	SM1	0	R/W	Source Address Mode
vw.DataShee	SM0	0	R/W	SM1 and SM0 select whether the DMA source address is incremented, decremented, or left fixed. (In single address mode, SM1 and SM0 bits are ignored when data is transferred from an external device with DACK.)
				00: Fixed source address (setting prohibited in 16-byte transfer)
				01: Source address is incremented (+1 in 8-bit transfer, +2 in 16-bit transfer, +4 in 32-bit transfer, +16 in 16-byte transfer)
				10: Source address is decremented (–1 in 8-bit transfer, –2 in 16-bit transfer, –4 in 32-bit transfer; illegal setting in 16-byte transfer)
				11: Reserved (setting prohibited)

Bit	Bit Name	Initial Value	R/W	Descriptions
0	DE	0	R/W	DMA Enable
				This bit enabler or disables the DMA transfer. In an auto request mode, DMA transfer starts by setting the DE bit and DME bit in DMAOR to 1. In this time, all of the bits TE, NMIF in DMAOR, and AE must be 0's. In an external request or peripheral module request, DMA transfer starts if DMA transfer request is generated by the devices or peripheral modules after setting the bits DE and DME to 1. In this case, however, all of the bits TE, NMIF, and AE must be 0's an in the case of auto request mode. Clearing the DE bit to 0 can terminate the DMA transfer.
				0: DMA transfer disabled
				1: DMA transfer enabled

Note: \* Writing 0 is possible to clear the flag.

MAN DataShootAll con

## 10.3.5 DMA Initial Address Register (IAR)

IAR is a 32-bit readable/writable register that specifies the initial address of SAR or DAR for repeating the DMA transfer.

To transfer data in 16 bits or in 32 bits, specify the address with 16-bit or 32-bit address boundary. When transferring data in 16-byte units, a 16-byte boundary must be set for the source address value. IAR is undefined at reset and retains the current value in standby or module standby mode.

## 10.3.6 DMA Operation Register (DMAOR)

DMAOR is a 32-bit readable/writable register that specifies the priority level of channels at the DMA transfer. This register shows the DMA transfer status. DMAOR is undefined at reset and retains the current value in the standby or module standby mode.

Bit	Bit Name	Initial Value	R/W	Description
D <del>ataShe</del> 31	et4U.eem	All 0	R	Reserved
_		All U	n	
30				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
29	CMS1	0	R/W	Cycle Steal Mode Select 1, 0
28	CMS0	0	R/W	These bits select either normal mode or intermittent mode in cycle steal mode.
				It is necessary that the bus modes of all channels be set to cycle steal mode to make the intermittent mode valid.
				00: Normal mode
				01: Reserved (setting prohibited)
				10: Intermittent mode 16
				Executes one DMA transfer in each of 16 clocks of an external bus clock.
				11: Intermittent mode 64
				Executes one DMA transfer in each of 64 clocks of an external bus clock.
27	_	All 0	R	Reserved
26				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

			Initial		
	Bit	Bit Name	Value	R/W	Description
	25	PR1	0	R/W	Priority Mode
	24	PR0	0	R/W	PR1 and PR0 select the priority level between channels when there are transfer requests for multiple channels simultaneously.
					00: Fixed mode 1: CH0 > CH1 > CH2 > CH3
					01: Fixed mode 2: CH0 > CH2 > CH3 > CH1
					10: The status of the channel select round-robin mode: RCn bit is reflected to the priority.
					11: All channel round-robin mode
	23 to 19	_	All 0	R	Reserved
_					These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
	18	AE	0	R/(W)*	Address Error Flag
_	taSheet4U				AE indicates that an address error occurred during DMA transfer. When the AE bit is set, the DMA transfer is not enabled even if the DE bit of CHCR and the DME bit of DMAOR are set to 1. This bit can only be cleared by writing 0 after reading 1.
					0: No DMAC address error
					Clear conditions: Writing AE = 0 after AE = 1 read
					1: DMAC address error
	17	NMIF	0	R/(W)*	NMI Flag
					NMIF indicates that an NMI interrupt occurred. When the NMIF bit is set, the DMA transfer is not enabled even if the DE bit of CHCR and the DME bit of DMAOR are set to 1. Only 0 can be written to clear this bit after 1 is read.
					When the NMI is input, the DMA transfer in progress can be done in one transfer unit. When the DMAC is not in operational, the NMIF bit is set to 1 even if the NMI interrupt was input.
					0: No NMI input
					Clearing conditions: Writing NMIF = 0 after NMIF = 1 read
					1: NMI interrupt occurs

		Initial		
Bit	Bit Name	Value	R/W	Description
16	DME	0	R/W	DMA Master Enable
				DME enables or disables DMA transfers on all channels. If the DME bit and the DE bit corresponding to each channel in CHCR are set to 1, transfer is enabled in the corresponding channel. If this bit is cleared during transfer, transfers in all the channels can be suspended.
				0: Disable DMA transfers on all channels
				1: Enable DMA transfers on all channels
15 to 0	) —	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

Note: \* Writing 0 is possible to clear the flag.

# 10.3.7 DMA Extension Resource Selector 0 and 1 (DMARS0 and DMARS1)

DMARS is a 16-bits readable/writable register that specifies the DMA transfer sources from peripheral modules in each channel. DMARS0 specifies for channels 0 and 1, DMARS1 specifies for channels 2 and 3.

The DMARS0 and DMARS1 are initialized at reset and retain the current values in standby or module standby mode.

Transfer requests from the various modules are specified by the MID and RID as shown in table 10.2. When MID/RID other than the values listed in table 10.2 is set, the operation of this LSI is not guaranteed. The transfer request from the DMARS register is valid only when the resource select bits (RS3 [3:0]) has been set to B'1000 for CHCR0 to CHCR3 registers. Otherwise, even if the DMARS has been set, transfer request source is not accepted.

## 10.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto request, external request, and on-chip module request. The dual address mode has direct address transfer mode and indirect address transfer mode. In the bus mode, the burst mode or the cycle steal mode can be selected.

#### 10.4.1 DMA Transfer Flow

After the DMA source address registers (SAR), DMA destination address registers (DAR), DMA transfer count registers (DMATCR), DMA channel control registers (CHCR), DMA operation register (DMAOR), and DMA extension resource source selector (DMARS) are set, the DMAC transfers data according to the following procedure:

- 1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0)
- 2. When a transfer request comes and transfer is enabled, the DMAC transfers 1 transfer unit of data (depending on the TS0 and TS1 settings). For an auto request, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented for each transfer. The actual transfer flows vary by address mode and bus mode.
  - 3. When the specified number of transfer have been completed (when DMATCR reaches 0), the transfer ends normally. If the IE bit of the CHCR is set to 1 at this time, a DEI interrupt is sent to the CPU. If the RPT bit is set to 1, the IAR value is set in SAR or DAR and DMATCR is initialized to the written value. In this case, transfer can be continued only by clearing the TE bit.
- 4. When an NMI interrupt is generated, the transfer is aborted. Transfers are also aborted when the DE bit of the CHCR or the DME bit of the DMAOR are changed to 0.

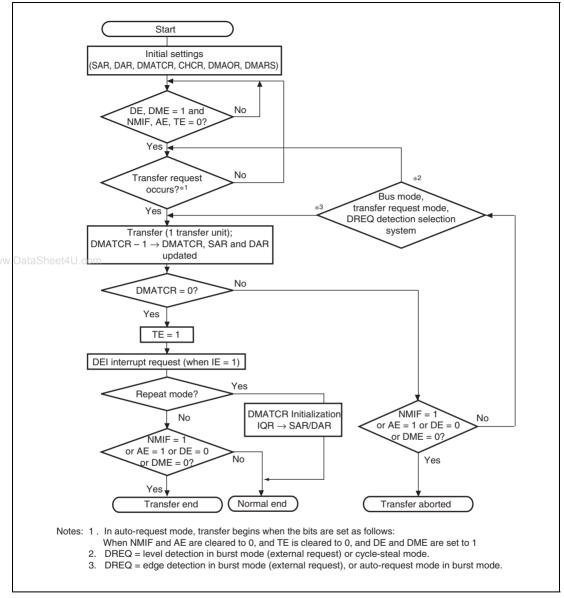

Figure 10.2 DMA Transfer Flowchart

### 10.4.2 Repeat Mode Transfer

The repeat mode of DMAC can be used by setting 1 to the RPT bit of the CHCR\_n register. When the repeat mode is set and data transfer ends (DMATCR\_n becomes 0), the DEI interrupt is generated if the IE bit of CHCR\_n is set, and then the value of IAR\_n is copied onto SAR\_n or DAR\_n specified by RAS bit of CHCR\_n, and DMATCR\_n is restored to an initial value. DMA transfer can be executed continuously when the TE bit of the CHCR\_n register is cleared to 0.

#### 10.4.3 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated by devices and on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in three modes: auto request, external request, and on-chip module request. The request mode is selected in the RS3 to RS0 bits of the DMA channel control registers 0 to 3 (CHCR\_0 to CHCR\_3), and the DMA extension resource selectors 0 and 1 (DMARS0 and DMARS1).

www.DataSheet411.com

**Auto-Request Mode:** When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, the auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bits of CHCR\_0 to CHCR\_3 and the DME bit of the DMAOR are set to 1, the transfer begins so long as the TE bits of CHCR\_0 to CHCR\_3 and the NMIF bit of DMAOR are all 0.

**External Request Mode:** In this mode a transfer is performed at the request signal (DREQ) of an external device. This is valid only for DMA channel 0. Choose one of the modes shown in table 10.3 according to the application system. When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0), a transfer is performed upon a request at the DREQ input.

Table 10.3 Selecting External Request Modes with the RS Bits

RS3	RS2	RS1	RS0	Address Mode	Source	Destination
0	0	0	0	Dual address mode	Any	Any
0	0	1	0	Single address mode	External memory, memory-mapped external device	External device with DACK
			1		External device with DACK	External memory, memory-mapped external device

Choose to detect DREQ by either the edge or level of the signal input with the DREQ level (DL) bit and DS bit of CHCR\_0 as shown in table 10.4. The source of the transfer request does not have to be the data transfer source or destination.

Table 10.4 Selecting External Request Detection with DL, DS Bits

CHCR		
DL	DS	Detection of External Request
0	0	Low level detection
	1	Falling edge detection
1	0	High level detection
	1	Rising edge detection

When DREQ is accepted, the DREQ pin becomes request accept disabled state (non-sensitive period). After issuing acknowledge signal DACK for the accepted DREQ, the DREQ pin again becomes request accept enabled state.

When DREQ is used by level detection, there are following two cases by the timing to detect the next DREQ after outputting DACK.

Overrun0: Transfer is aborted after the same number of transfer has been performed as requests.

Overrun1: Transfer is aborted after transfers have been performed for (the number of requests plus 1) times.

The DO bit in CHCR selects this overrun 0 or overrun 1. (Table 10.5)

Table 10.5 Selecting External Request Detection with DO Bit

CHCK		
DO	External Request	
0	Overrun 0	
1	Overrun 1	

**On-Chip Peripheral Module Request:** In this mode (table 10.6), the transfer is performed in response to the transfer request signal (interrupt request signal) of an on-chip peripheral module. Transfer request signals comprise the transmit data empty transfer request and receive data full transfer request from the SCIF0, SCIF1, SIOF, and USBF.

When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0), a transfer is performed upon the input of a transfer request signal.

www.DataSheet4U.com

CHCD

When a transmit data empty transfer request of SCIF is set as the transfer request, the transfer destination must be the SCIF's transmit data register. Likewise, when the SCIF receive data full transfer request is set as the transfer request, the transfer source must be the SCIF's receive data register. These conditions also apply to the SIOF and USBF.

Table 10.6 Selecting On-Chip Peripheral Module Request Modes with the RS3 to RS0 Bits

CHCR DMARS			DMA Transfer	D			_

	1000	001000	01	SCIF0 transmitter	TDFE(transmit data FIFO empty interrupt)	Any	SCFTDR_0	Cycle steal
			10	SCIF0 receiver	RDF (receive data FIFO full interrupt)	SCFRDR_0	Any	Cycle steal
		001010	01	SCIF1 transmitter	TDFE (transmit data FIFO empty interrupt)	Any	SCFTDR_1	Cycle steal
			10	SCIF1 receiver	RDF (receive data FIFO full interrupt)	SCFRDR_1	Any	Cycle steal
	oto Cho o t41	010101	01	SIOF transmitter	TDFE (transmit data FIFO empty interrupt)	Any	SIOF/SITDR_0	Cycle steal
/. Da	ataSheet4l		10	SIOF receiver	RDF (receive data FIFO full interrupt)	SIOF/SIRDR_0	Any	Cycle steal
		011100	11	USBF transmitter 0	Transmit data empty request 0	Any	EPDR2i, 5	Cycle steal
				USBF receiver 0	Receive data full request 0	EPDR2o, 6	Any	Cycle steal
			00	USBF transmitter 1	Transmit data empty request 1	Any	EPDR2i, 5	Cycle steal
				USBF receiver 1	Receive data full request 1	EPDR20, 6	Any	Cycle steal

### 10.4.4 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it selects a channel according to a predetermined priority order. The four modes (fixed mode 1, fixed mode 2, channel selective round-robin mode, and all-channel round-robin mode) are selected using the bits PR1 and PR0 in DMAOR

**Fixed Mode:** In these modes, the priority levels among the channels remain fixed. There are two kinds of fixed modes as follows:

Fixed mode 1: CH0 > CH1 > CH2 > CH3

Fixed mode 2: CH0 > CH2 > CH3 > CH1

These are selected by the bits PR1 and the PR0 in DMAOR.

**Round-Robin Mode:** Each time one word, byte, longword, or 16-byte is transferred on one channel, the priority order is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority order. The round-robin mode operation is shown in figure 10.3. The priority of the round-robin mode is CH0 > CH1 > CH2 > CH3 immediately after reset. When round-robin mode is selected, cycle steal mode and burst mode should not be mixed as the bus mode of two or more channels.

www.DataSheet4U.com

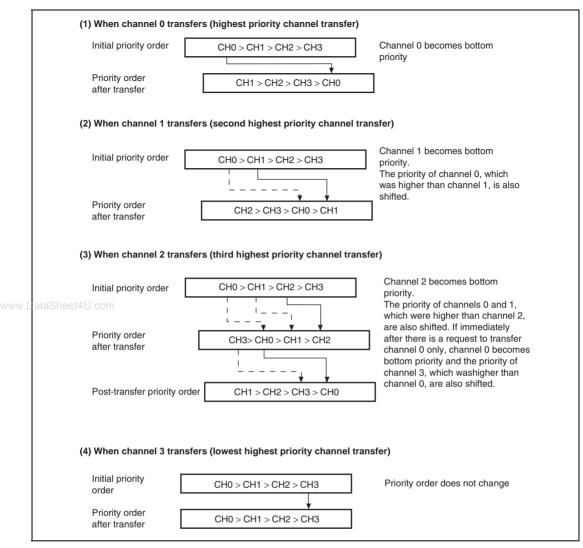

Figure 10.3 Round-Robin Mode

Figure 10.4 shows how the priority order changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

- 1. Transfer requests are generated simultaneously to channels 0 and 3.
- 2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
- 3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
- 4. When the channel 0 transfer ends, channel 0 becomes lowest priority www.DataSheet4U.com

- 5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
- 6. When the channel 1 transfer ends, channel 1 becomes lowest priority.
- 7. The channel 3 transfer begins.
- 8. When the channel 3 transfer ends, channels 3 and 2 shift downward in priority so that channel 3 becomes the lowest priority.

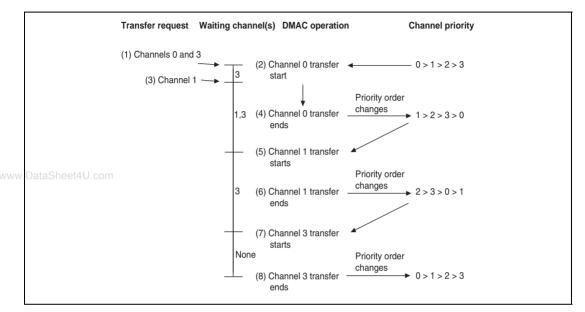

Figure 10.4 Changes in Channel Priority in Round-Robin Mode

### 10.4.5 DMA Transfer Types

DMA transfer has two types; single address mode transfer and dual address mode transfer, they depend on the number of bus cycles of access to source and destination. A data transfer timing depends on the bus mode, which has cycle steal mode and burst mode. The DMAC supports the transfers shown in table 10.7.

**Table 10.7 Supported DMA Transfers** 

	Destination					
Source	External Device with DACK	External Memory	Memory- Mapped External Device	On-Chip Peripheral Module	X/Y Memory U Memory	
External device with DACK	Not available	Dual, single	Dual, single	Not available	Not available	
External memory	Dual, single	Dual	Dual	Dual	Dual	
Memory-mapped external device	Dual, single	Dual	Dual	Dual	Dual	
On-chip peripheral module	Not available	Dual	Dual	Dual	Dual	
X/Y memory, U memory	Not available	Dual	Dual	Dual	Dual	

Notes: 1. Dual: Dual address mode

2. Single: Single address mode

3. 16-byte transfer is not available for on-chip peripheral modules.

#### **Address Modes:**

#### Dual Address Mode

In the dual address mode, both the transfer source and destination are accessed (selected) by an address. The source and destination can be located externally or internally.

DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in figure 10.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a write cycle.

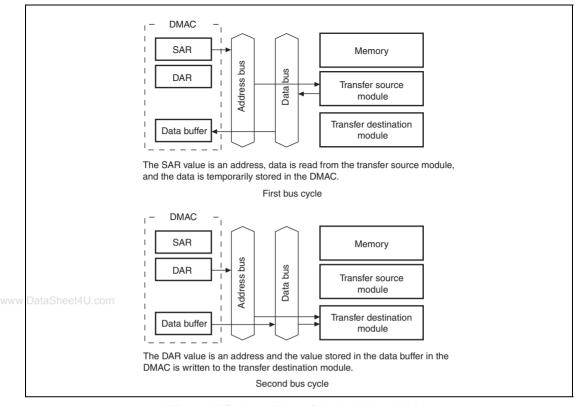

Figure 10.5 Data Flow of Dual Address Mode

Auto request, external request, and on-chip peripheral module request are available for the transfer request. DACK can be output in read cycle or write cycle in dual address mode. The AM bit of the channel control register (CHCR) can specify whether the DACK is output in read cycle or write cycle.

Figure 10.6 shows an example of DMA transfer timing in dual address mode.

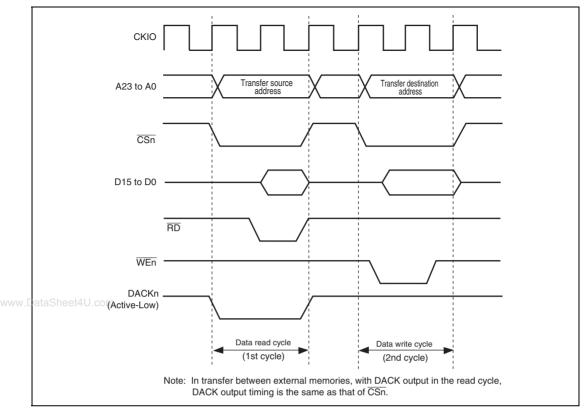

Figure 10.6 Example of DMA Transfer Timing in Dual Mode (Source: Ordinary memory, Destination: Ordinary memory)

#### 2. Single Address Mode

In single address mode, either the transfer source or transfer destination peripheral device is accessed (selected) by means of the DACK signal, and the other device is accessed by address. In this mode, the DMAC performs one DMA transfer in one bus cycle, accessing one of the external devices by outputting the DACK transfer request acknowledge signal to it, and at the same time outputting an address to the other device involved in the transfer. For example, in the case of transfer between external memory and an external device with DACK shown in figure 10.7, when the external device outputs data to the data bus, that data is written to the external memory in the same bus cycle.

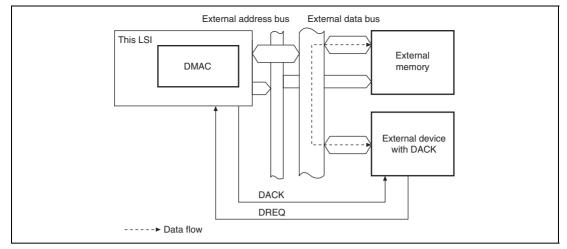

Figure 10.7 Data Flow in Single Address Mode

Two kinds of transfer are possible in single address mode: (1) transfer between an external device with DACK and a memory-mapped external device, and (2) transfer between an external device with DACK and external memory. In both cases, only the external request signal (DREQ) is used for transfer requests.

Figures 10.8 shows an example of DMA transfer timing in single address mode.

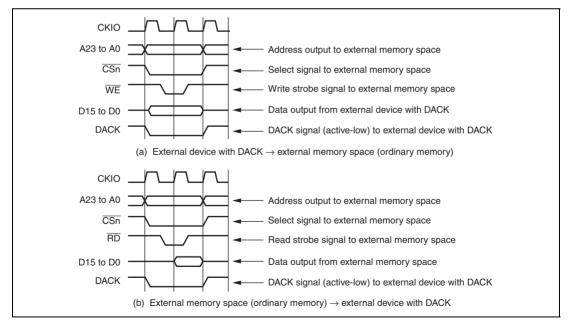

Figure 10.8 Example of DMA Transfer Timing in Single Address Mode

**Bus Modes:** There are two bus modes: cycle steal and burst. Select the mode in the TB bits of the channel control register (CHCR).

- 1. Cycle-Steal Mode
- Normal mode

In the normal mode of cycle-steal, the bus mastership is given to another bus master after a one-transfer-unit (byte, word, long-word, or 16 bytes unit) DMA transfer. When another transfer request occurs, the bus masterships are obtained from the other bus master and a transfer is performed for one transfer unit. When that transfer ends, the bus mastership is passed to the other bus master. This is repeated until the transfer end conditions are satisfied. In the cycle-steal mode, transfer areas are not affected regardless of settings of the transfer request source, transfer source, and transfer destination.

Figure 10.9 shows an example of DMA transfer timing in the cycle steal mode. Transfer conditions shown in the figure are:

- 1. Dual address mode
- 2. DREQ low level detection

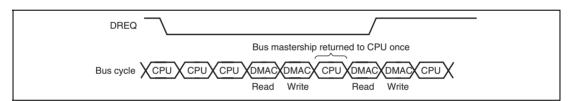

Figure 10.9 DMA Transfer Example in the Cycle-Steal Normal Mode (Dual Address, DREQ Low Level Detection)

Intermittent Mode 16 and Intermittent Mode 64

In the intermittent mode of cycle steal, DMAC returns the bus mastership to other bus master whenever a unit of transfer (byte, word, longword, or 16 bytes) is complete. If the next transfer request occurs after that, DMAC gets the bus mastership from other bus master after waiting for 16 or 64 clocks in B $\phi$  count. DMAC then transfers data of one unit and returns the bus mastership to other bus master. These operations are repeated until the transfer end condition is satisfied. It is thus possible to make lower the ratio of bus occupation by DMA transfer than the normal mode of cycle steal.

When DMAC gets again the bus mastership, DMA transfer can be postponed in case of entry updating due to cache miss.

This intermittent mode can be used for all transfer section; transfer requester, source, and destination. The bus modes, however, must be cycle steal mode in all channels.

Figure 10.10 shows an example of DMA transfer timing in cycle steal intermittent mode. Transfer conditions shown in the figure are:

- 1. Dual address mode
- 2. DREQ low level detection

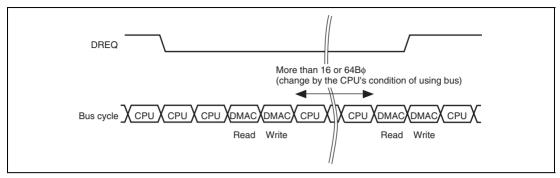

Figure 10.10 Example of DMA Transfer in Cycle Steal Intermittent Mode (Dual address, DREQ low level detection)

#### 2. Burst Mode

Once the bus mastership is obtained, the transfer is performed continuously until the transfer end condition is satisfied. In the external request mode with low level detection of the DREQ pin, however, when the DREQ pin is driven high, the bus passes to the other bus master after the DMAC transfer request that has already been accepted ends, even if the transfer end conditions have not been satisfied.

The burst mode cannot be used for other than CMT00, CMT01, CMT02, and CMT03 when the on-chip peripheral module is the transfer request source. Figure 10.11 shows DMA transfer timing in the burst mode.

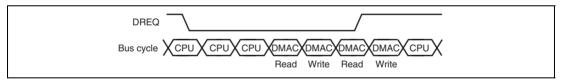

Figure 10.11 DMA Transfer Example in the Burst Mode (Dual Address, DREQ low level detection)

**Relationship between Request Modes and Bus Modes by DMA Transfer Category:** Table 10.9 shows the relationship between request modes and bus modes by DMA transfer category.

Table 10.8 Relationship of Request Modes and Bus Modes by DMA Transfer Category

Addres s Mode	Transfer Category	Request Mode	Bus Mode	Transfer Size (bits)	Usable Channels
Dual	External device with DACK and external memory	External	B/C	8/16/32/128	0
	External device with DACK and memory- mapped external device	External	B/C	8/16/32/128	0
	External memory and external memory	External /auto	B/C	8/16/32/128	0 to 5*3
	External memory and memory-mapped external device	External /auto	B/C	8/16/32/128	0 to 5*3
	Memory-mapped external device and memory-mapped external device	External /auto	B/C	8/16/32/128	0 to 5*3
	External memory and on-chip peripheral module	All*1	С	8/16/32/128*2	0 to 5*3
	Memory-mapped external device and on-chip peripheral module	All* <sup>1</sup>	С	8/16/32/128*2	0 to 5*3
	On-chip peripheral module and on-chip peripheral module	All*1	С	8/16/32/128*2	0 to 5*3
	X/Y memory, U memory and X/Y memory, U memory	External /auto	B/C	8/16/32/128	0 to 5*3
	X/Y memory, U memory and memory- mapped external device	External /auto	B/C	8/16/32/128	0 to 5*3
	X/Y memory, U memory and on-chip peripheral module	All*1	С	8/16/32/128*2	0 to 5*3
	X/Y memory, U memory and external memory	External /auto	B/C	8/16/32/128	0 to 5*3
Single	External device with DACK and external memory	External	B/C	8/16/32/128	0
	External device with DACK and memory-mapped external device	External	B/C	8/16/32/128	0

B: Burst, C: Cycle steal

- Notes: 1. External requests, auto requests, and on-chip peripheral module requests are all available. In the case of on-chip peripheral module requests, transfer source register should be the transfer source or transfer.
  - 2. Access size permitted for the on-chip peripheral module register functioning as the transfer source or transfer destination.
  - 3. If the transfer request is an external request, only channel 0 is available.

**Bus Mode and Channel Priority Order:** When a given channel 1 is transferring in burst mode and there is a transfer request to a channel 0 with a higher priority in fixed mode (CH0 > CH1), the transfer of channel 0 will begin immediately.

At this time, the channel 1 transfer will continue when the channel 0 transfer has completely finished, even if channel 0 is operating in burst mode.

When channel 0 is operating in cycle steal mode, 1 will begin operating again without releasing bus mastership after channel 0 with a higher priority completes the transfer of one transfer unit. Then transfer is carried out between the two channels in the order channel 0, channel 1, channel 0, channel 1. In other words, the CPU cycle after transfer in cycle steal mode is switched with transfer in burst mode (hereafter, this is called preferential execution of burst mode). This example is shown in figure 10.12. When more than two channels in burst mode are conflicted, transfer on a channel with highest priority among those channels is executed.

When transfers of more than two channels are performed, the bus is not given to the bus master until conflicted transfers in burst mode have been completed.

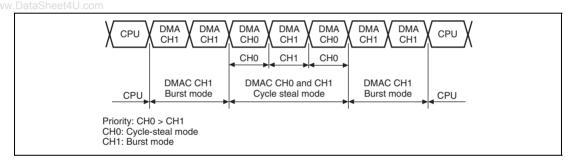

Figure 10.12 Bus State when Multiple Channels Are Operating

The priority order in round-robin mode is changed as is shown in figure 10.3. Note that in the burst mode, channel for cycle steal and channel for burst mode should not be mixed.

# 10.4.6 Number of Bus Cycle States and DREQ Pin Sampling Timing

**Number of Bus Cycle States:** When the DMAC is the bus master, the number of bus cycle states is controlled by the bus state controller (BSC) in the same way as when the CPU is the bus master. For details, see section 9, Bus State Controller (BSC).

**DREQ Pin Sampling Timing:** Figures 10.13 to 10.16 show the DREQ input sampling timings in each bus mode.

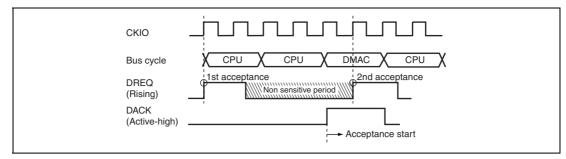

Figure 10.13 Example of DREQ Input Detection in Cycle Steal Mode Edge Detection

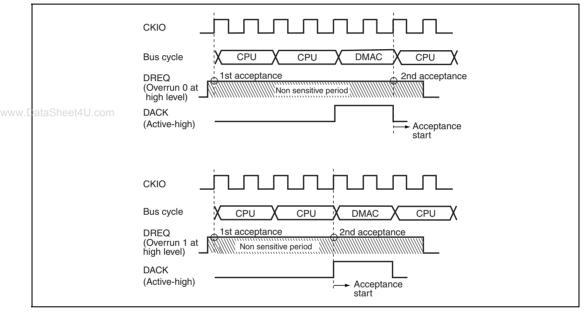

Figure 10.14 Example of DREQ Input Detection in Cycle Steal Mode Level Detection

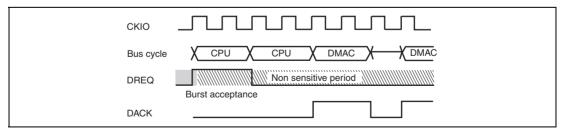

Figure 10.15 Example of DREQ Input Detection in Burst Mode Edge Detection

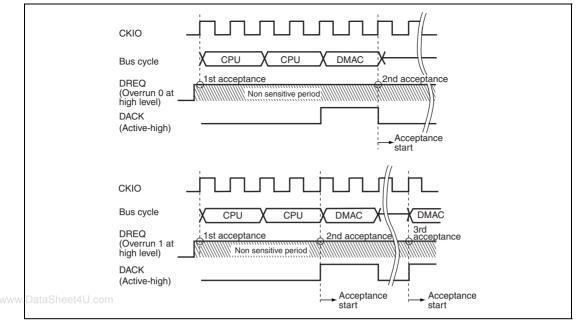

Figure 10.16 Example of DREQ Input Detection in Burst Mode Level Detection

Figure 10.17 shows the TEND output timing.

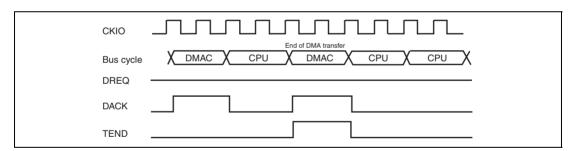

Figure 10.17 Example of DMA Transfer End Signal Timing in Cycle Steel Mode Level Detection

To execute a long word access to an 8-bit or 16-bit external device or to execute a word access to an 8-bit external device, the DACK and TEND outputs are divided for data alignment as shown in figure 10.18.

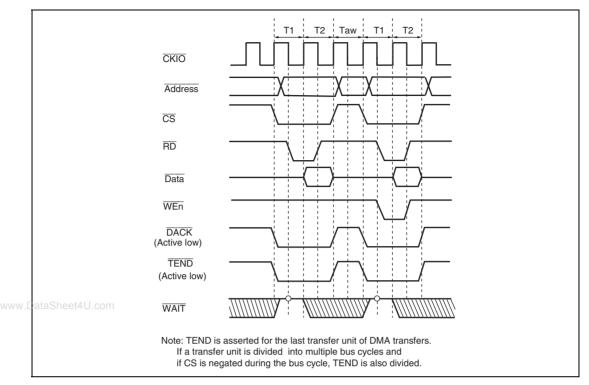

Figure 10.18 BSC Ordinary Memory Access (No wait, Idle Cycle 1, Longword Access to 16-bit Device)

# 10.5 Usage Notes

**Rewriting Channel Control Register (CHCR\_n):** When rewriting a channel control register (CHCR\_n) of each DMAC channel, the DE bit of corresponding channel should be cleared to 0 precedently.

Shift to Power-Down Mode: Note that shifting to standby mode or module standby state by setting the module standby bit in DMAC should not be performed during DMA transfer. When shifting to software standby mode or module standby state, the DE bit of all channels should be cleared to 0 precedently.

vww.DataSheet4U.con

# Section 11 Clock Pulse Generator (CPG)

This LSI has a clock pulse generator (CPG) that generates an internal clock ( $I\phi$ ), a peripheral clock ( $P\phi$ ), and a bus clock ( $B\phi$ ). The CPG consists of an oscillator, PLL circuit, and divider circuit.

#### 11.1 Features

- Three clock modes
  - Selection of three clock modes by frequency range, turning on and off the PLL, a direct connection to a crystal unit, and external clock input.
- Three clocks generated independently
  - An internal clock for the CPU and cache ( $I\phi$ ); a peripheral clock ( $P\phi$ ) for the on-chip circuits; a bus clock ( $B\phi$  = CKIO) for the external bus interface.
- Frequency change function
- Internal and peripheral clock frequencies can be changed independently using the PLL (phase www.DataStlocked loop) circuit and divider circuit within the CPG. Frequencies are changed by software using frequency control register (FRQCR) settings.
  - Power-down mode control
    - The clock can be stopped for sleep mode and software standby mode and specific modules can be stopped using the module standby function.

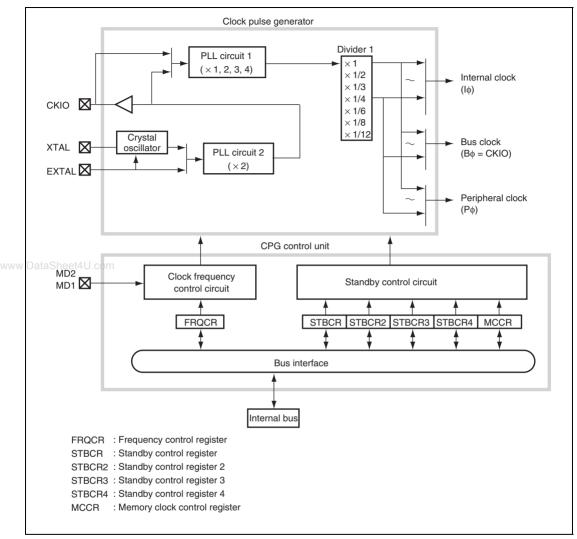

Figure 11.1 Block Diagram of Clock Pulse Generator

The clock pulse generator blocks function as follows:

**PLL Circuit 1:** PLL circuit 1 multiplies the input clock frequency by 1, 2, 3 or 4 from the CKIO pin. The multiplication rate is set using the frequency control register (FRQCR). When this is done, the phases of the leading edge of the internal clock, bus clock, and peripheral clock are controlled so that those will agree with the phase of the leading edge of the CKIO pin.

**PLL Circuit 2:** PLL circuit 2 doubles the input clock frequency from the crystal oscillator or EXTAL pin. The multiplication rate is fixed according to the clock operating mode. The clock operating mode is specified by the MD1 and MD2 pins. For details on clock operating mode, see table 11.2.

**Crystal Oscillator:** The crystal oscillator is an oscillator circuit in which a crystal resonator is connected to the XTAL pin or EXTAL pin. This can be used according to the clock operating mode 6.

**Divider 1:** Divider 1 generates a clock at the operating frequency used by the internal, bus, or peripheral clock. The operating frequency can be 1, 1/2, 1/3, 1/4, 1/6, 1/8, or 1/12 times the output frequency of PLL circuit 1, as long as it stays at or above the clock frequency of the CKIO pin. The division ratio is set in the frequency control register (FRQCR). \*

Note: \* Internal and peripheral clocks can be selected independently using the frequency control register (FRQCR). However, even though it is the selectable combination, if the number of operation frequencies which surpasses upper limit value of each operating frequency is set, operation of this LSI can not be guaranteed. Since operation frequency of bus clock should be the same as that of the CKIO, the division ratio is automatically set using the multiplication rate of PLL circuit 1.

**Clock Frequency Control Circuit:** The clock frequency control circuit controls the clock frequency using the MD1 and MD2 pins and the frequency control register (FRQCR).

**Standby Control Circuit:** The standby control circuit controls the states of the clock pulse generator and other modules during clock switching or sleep, or standby modes.

**Frequency Control Register:** The frequency control register (FRQCR) has control bits assigned for the following functions: clock output/non-output from the CKIO pin, the frequency multiplication ratio of PLL circuit 1, and the frequency division ratio of the internal clock and the peripheral clock.

**Standby Control Register:** The standby control registers (STBCR, STBCR2 to STBCR4) have bits for controlling the power-down modes. See section 13, Power-Down Modes, for more information.

Memory Clock Control Register: The memory clock control register (MCCR) has the memory clock in sleep and the control bits of 32-k clock oscillator for BT. For more information on MCCR, see section 13, Power-Down Mode.

www.DataSheet4U.com

# 11.2 Input/Output Pins

Table 11.1 lists the CPG pins and their functions.

**Table 11.1 Clock Pulse Generator Pins Configuration** 

Pin Name	I/O	Function
MD1	Input	Mode control pin
		Set the clock operating mode
MD2	Input	Mode control pin
		Set the clock operating mode
XTAL	Output	Crystal output pin
		Connected to the crystal resonator
EXTAL	Input	Crystal input pin (clock input pin)
		Connected to the crystal resonator or used to input an external clock
CKIO	Input/	Clock input/output pin
ataSheet4U.com	Output	Used as the external clock input or output pin

## 11.3 Clock Operating Modes

Table 11.2 shows the relationship between the mode control pins (MD2 and MD1) combinations and the clock operating modes. Table 11.3 shows the usable frequency ranges in the clock operating.

**Table 11.2 Clock Operating Modes** 

	Pin	Values	Clock I/O			СКІО	
Mode	MD2	MD1	Source	Output	PLL2 On/Off	PLL1 On/Off	Frequency
5	1	0	EXTAL	CKIO	ON (×2)	ON (×1, 2, 3, 4)	(EXTAL) ×2
6	0	0	Crystal resonator	CKIO	ON (×2)	ON (×1, 2, 3, 4)	(Crystal resonator) ×2
7	1	1	CKIO	_	OFF	ON (×1, 2, 3, 4)	(CKIO)

**Mode 5:** This LSI is supplied with a clock that is doubled by the PLL circuit 2 after receiving an external clock from the EXTAL pin. This reduces the frequency of the externally generated clock. Input clock frequency and CKIO frequency range from 10 MHz to 30 MHz and from 20 MHz to 60 MHz, respectively.

**Mode 6:** This LSI is supplied with a clock that is doubled by the PLL circuit 2 after operating the on-chip crystal oscillator. This reduces the frequency of the externally generated clock. Input clock frequency and CKIO frequency range from 10 MHz to 30 MHz and from 20 MHz to 60 MHz, respectively.

**Mode 7:** In this mode, the CKIO pin functions as an input. This LSI is supplied with a clock that is wave-formed and multiplied by PLL circuit 1 and multiplied after receiving an external clock. This mode is effective for connecting synchronous DRAM because the PLL circuit 1. Input clock frequency (CKIO frequency) range from 20 MHz to 60 MHz.

Table 11.3 Possible Combination of Clock Modes and FRQCR Values

	Mode	FRQCR Register Value	PLL Circuit 1	PLL Circuit 2	Clock Ratio (lφ:Βφ:Ρφ)	Input Clock Frequency Range	CKIO Pin Frequency Range
	5, 6	H'1000	ON (×1)	ON (×2)	2:2:2	10MHz to 15MHz	20MHz to 30MHz

	H'1333	ON (×4)	OFF	1:1:1	20MHz to 30MHz	20MHz to 30MHz

- Notes: 1. Initial value immediately after reset in each mode.
  - 2. The value is settable when the boot function is used.

The boot function should not be used with values other than these values. There is a limitation in the SCIF transfer rate which can be set according to the input clock frequency. Refer to section 17.5.2, Clock Frequency and Data Transfer Rate when Using Boot Function in section 17, Boot Function (BOOT) for detail.

#### Cautions:

- 1. Input of divider circuit 1 becomes PLL circuit 1 output
- 2. Input of PLL circuit 1 becomes:

CKIO pin input in mode 7

PLL circuit2 output in modes 5 and 6

3. The frequency of the internal clock becomes: The product of the frequency of the CKIO pin, the frequency multiplication ratio of PLL

circuit 1, and the division ratio of divider 1 Set the internal clock frequency not more 120 MHz (T.B.D). Do not set the internal clock frequency lower than the frequency of the CKIO pin.

4. The frequency of the peripheral clock becomes:

The product of the frequency of the CKIO pin, the frequency multiplication ratio of PLL circuit 1, and the division ratio of divider 1. Set the peripheral clock frequency lower than or equal to 30 MHz. Note that the frequency should not be higher than the CKIO pin frequency.

- 5.  $\times 1, \times 2, \times 3$ , or  $\times 4$  can be used as the multiplication ratio of PLL circuit 1.  $\times 1, \times 1/2, \times 1/3$ ,  $\times 1/4, \times 1/6, \times 1/8$  and  $\times 1/12$  can be selected as the division ratios of divider 1. Set the rate using frequency control register (FRQCR).
- 6. The output frequency of PLL circuit 1 is the product of the CKIO frequency and the multiplication ratio of PLL circuit 1. Use the output frequency not more than 120 MHz (T.B.D).
- 7. Bus clock frequency is always set to be equal to the frequency of the CKIO pin.
- 8. Clock ratios in table 11.3 are ratios of each frequency to one input clock frequency.

Operation of this LSI cannot be guaranteed using combinations other than those in table 11.3.

# 11.4 Register Descriptions

The CPG has the following registers. Refer the section 27, List of Registers, for the addresses of the registers and the register states in each operating mode.

- Frequency control register (FRQCR)
- Memory clock control register (MCCR)\*
- Standby control register (STBCR, STBCR2 to STBCR4)\*

Note: \* For further information on MCCR, STBCR, and STBCR2 to STBCR4, see section 13 Power-Down Mode

## 11.4.1 Frequency Control Register (FRQCR)

FROCR is a 16-bit readable/writable register used to specify whether a clock is output from the CKIO pin at standby mode, the frequency multiplication ratio of PLL circuit 1, and the frequency division ratio of the internal clock and the peripheral clock.

Only word access can be used on the FRQCR register.

This register is initialized by power-on reset from the  $\overline{RESETP}$  pin and retains the previous value after manual reset and standby mode.

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
12	CKOEN	1	R/W	Clock Output Enable
				When the HIZCNT bit in CMNCR is set to 1, CKOEN specifies whether a clock is output from the CKIO pin, or whether the CKIO pin is placed in the level-fixed state during release of the standby mode. If CKOEN is cleared to 0 and HIZCNT in CMNCR is set to 1, the CKIO pin is fixed at low. Therefore, the malfunction of an external circuit because of an unstable CKIO clock during release of the standby mode can be prevented. In clock operating mode 7, the CKIO pin functions as an input regardless of this bit value.
ataSheet4U				<ol><li>CKIO pin goes low during release of the standby mode.</li></ol>
				1: Clock is output from CKIO pin
11	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.

Note: The operations in the prohibited setting are not guaranteed.

## 11.5 Changing the Frequency

The frequency of the internal clock and peripheral clock can be changed either by changing the multiplication rate of PLL circuit 1 or by changing the division rates of divider 1. All of these are controlled by software through the frequency control register. The methods are described below.

#### 11.5.1 Changing the Multiplication Rate

A PLL settling time is required when the multiplication rate of PLL circuit 1 is changed. The onchip WDT counts the settling time.

- 1. In the initial state, the multiplication rate of PLL circuit 1 is 1.
- 2. Set a value that will become the specified oscillation settling time in the WDT and stop the WDT. The following must be set:

WTCSR register TME bit = 0: WDT stops

WTCSR register CKS2 to CKS0 bits: Division ratio of WDT count clock

WTCNT counter: Initial counter value

- 3. Set the desired value in the STC[2:0] bits. The division ratio can also be set in the IFC[2:0] and PFC[2:0] bits.
- 4. The processor pauses internally and the WDT starts incrementing. The internal, bus, and peripheral clocks stop and the WDT is supplied with the clock. The clock will continue to be output at the CKIO pin.
- 5. Supply of the clock that has been set begins at WDT count overflow, and the processor begins operating again. The WDT stops after it overflows.

Note: When changing the clock frequency multiplication ratio, clear both UMCLKC bit and XYMCLKC bit of memory clock control register (MCCR) to 0.

#### 11.5.2 Changing the Division Ratio

The WDT will not count unless the multiplication rate is changed simultaneously.

- 1. In the initial state, IFC[2:0] = B'000 and PFC[2:0] = B'011
- 2. Set the IFC[2:0] and PFC[2:0] bits to the new division ratio. The values that can be set are limited by the clock mode and the multiplication rate of PLL circuit 1. Note that if the wrong value is set, the processor will malfunction.
- 3. The clock is immediately supplied at the new division ratio.

## 11.6 Notes on Board Design

**Note on Using a Crystal Resonator:** When designing the board, place the crystal resonator, capacitors CL1 and CL2, and damping register R as close as possible to the XTAL and EXTAL pins. To prevent inductive interference in oscillation, ensure that the connection points of the capacitor to be connected to the crystal resonator are common and no other signal lines cross the signal lines for these pins.

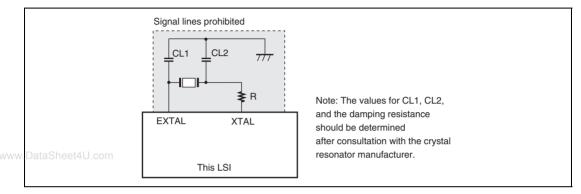

Figure 11.2 Note on Using a Crystal Resonator

**Notes on Bypass Capacitor:** A multilayer ceramic capacitor must be inserted for each pair of Vss and Vcc as a bypass capacitor. The bypass capacitor must be inserted as close as possible to the power supply pins of the LSI. Note that an appropriate bypass capacitor must be selected according to the capacitance and frequency of the LSI to be used.

**Notes on Using a PLL Oscillator Circuit:** Circuitry as shown in figure 11.3 is recommended around the PLL. In the Vcc and Vss connection pattern for the PLL, signal lines from the board power supply pins must be as short as possible and pattern width must be as wide as possible to reduce inductive interference.

In clock operating mode 7, the EXTAL pin is pulled up and the XTAL pin is left open.

Since the analog power supply pins of the PLL are sensitive to the noise, the system may malfunction due to inductive interference at the power supply pins. To prevent such malfunction, the analog power supply pin Vcc and digital power supply pin Vcc should not supply the same resources on the board if at all possible.

Please read "Vcc for PLL" above-mentioned as "VDD for PLL" when you do not select a built-in regulator (i.e. VDD external power supply is used).

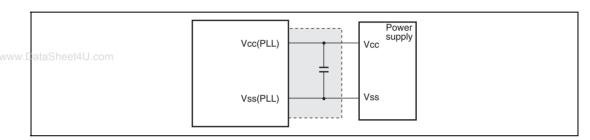

Figure 11.3 Note on Using a PLL Oscillator Circuit

# Section 12 Watchdog Timer (WDT)

This LSI includes the watchdog timer (WDT), which enables reset on overflow of the counter when the value of the counter has not been updated because of a system malfunction.

The watchdog timer (WDT) is a single-channel timer that uses a peripheral clock as an input and counts the clock settling time and is used to clear standby mode and temporary standbys, such as frequency changes. It can also be used as an interval timer.

#### 12.1 Features

The WDT has the following features:

- Can be used to ensure the clock settling time: Use the WDT to cancel a standby mode and the temporary standbys which occur when the clock frequency is changed.
- Can switch between watchdog timer mode and interval timer mode.
- www.DateSt Generates internal resets in watchdog timer mode: Internal resets occur after counter overflow.
  - Interrupt generation in interval timer mode

    An interval timer interrupt is generated when the counter overflows.
  - Choice of eight counter input clocks
     Eight clocks (×1 to ×1/4096) that are obtained by dividing the peripheral clock can be selected.
  - Power-on reset or manual reset can be selected as a reset

Figure 12.1 shows a block diagram of the WDT.

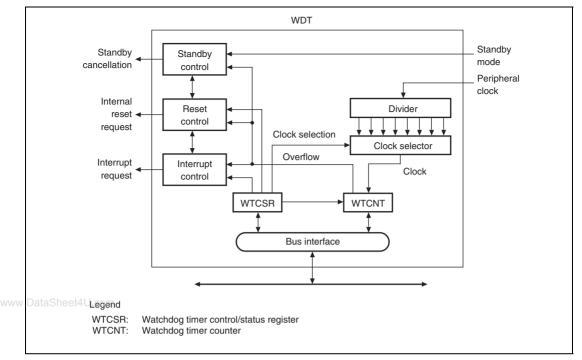

Figure 12.1 Block Diagram of the WDT

## 12.2 Register Descriptions

The WDT has the following two registers. Refer to the section 27, List of Registers, for the details of the addresses of these registers and the state of registers in each operating mode.

- Watchdog timer counter (WTCNT)
- Watchdog timer control/status register (WTCSR)

#### 12.2.1 Watchdog Timer Counter (WTCNT)

The watchdog timer counter (WTCNT) is an 8-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a reset in watchdog timer mode and an interrupt in interval timer mode. The WTCNT counter is initialized to H'00 only by a power-on reset caused by the RESETP pin. Use a word access to write to the WTCNT counter, writing H'5A in the upper byte. Use a byte access to read the WTCNT.

Note: 4 The WTCNT differs from other registers in the prevention of erroneous writes. See section 12.2.3, Notes on Register Access, for details.

#### 12.2.2 Watchdog Timer Control/Status Register (WTCSR)

The watchdog timer control/status register (WTCSR) is an 8-bit readable/writable register composed of bits to select the clock used for the count, bits to select the timer mode, overflow flags and enable bits. The WTCSR register holds its value in an internal reset due to WDT overflow. The WTCSR register is initialized only by a power-on reset via the RESETP pin.

When used to count the clock settling time for canceling a standby, it retains its value after counter overflow. Use a word access to write to the WTCSR counter, writing H'A5 in the upper byte. Use a byte access to read the WTCSR.

Note: The WTCNT differs from other registers in the prevention of erroneous writes. See section 12.2.3, Notes on Register Access, for details.

Bit	Bit Name	Initial Value	R/W	Description
7	TME	0	R/W	Timer Enable
				Starts and stops timer operation. Clear this bit to 0 when using the WDT in standby mode or when changing the clock frequency.
				Timer disabled     Count-up stops and WTCNT value is retained
				1: Timer enabled
6	WT/ĪT	0	R/W	Timer Mode Select
				Selects whether to use the WDT as a watchdog timer or an interval timer.
				0: Use as interval timer
				1: Use as watchdog timer
				Note: If WT/IT is modified when the WDT is running, the up-count may not be performed correctly.
a <del>j</del> aSheet4L	RSTS	0	R/W	Reset Select
				Selects the type of reset when the WTCNT overflows in watchdog timer mode. In interval timer mode, this setting is ignored.
				0: Power-on reset
				1: Manual reset
4	WOVF	0	R/W	Watchdog Timer Overflow
				Indicates that the WTCNT has overflowed in watchdog timer mode. This bit is not set in interval timer mode.
				0: No overflow
				1: WTCNT has overflowed in watchdog timer mode
3	IOVF	0	R/W	Interval Timer Overflow
				Indicates that the WTCNT has overflowed in interval timer mode. This bit is not set in watchdog timer mode.
				0: No overflow
				1: WTCNT has overflowed in interval timer mode

## 12.2.3 Notes on Register Access

The watchdog timer counter (WTCNT) and watchdog timer control/status register (WTCSR) are more difficult to write to than other registers. The procedures for reading writing to these registers are given below.

**Writing to WTCNT and WTCSR:** These registers must be written by a word transfer instruction. They cannot be written by a byte or longword transfer instruction. When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in figure 12.2. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

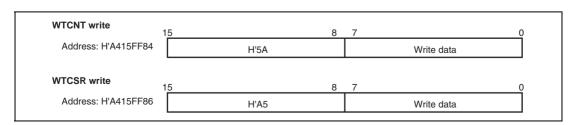

Figure 12.2 Writing to WTCNT and WTCSRwww.DataSheet4U.com

## 12.3 Operation

#### 12.3.1 Canceling Software Standby

The WDT can be used to cancel software standby mode with an interrupt such as an NMI interrupt. The procedure is described below. (The WDT does not operate when resets are used for canceling, so keep the RESETP pin low until the clock stabilizes.)

- 1. Before transitioning to software standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
- 2. Set the type of count clock used in the CKS2 to CKS0 bits in WTCSR and the initial values for the counter in the WTCNT. These values should ensure that the time till count overflow is longer than the clock oscillation settling time. This setting does not depend on a value of the WT/TT bit.
- 3. Move to standby mode by executing a SLEEP instruction to stop the clock.
- www.D4;aSThetWDT starts counting by detecting the edge change of the NMI signal.
  - 5. When the WDT count overflows, the CPG starts supplying the clock and the processor resumes operation. The WOVF and IOVF flags in WTCSR are not set when this happens.
  - 6. Since the WDT continues counting from H'00, set the STBY bit in the STBCR register to 0 in the interrupt processing program and this will stop the WDT. When the STBY bit remains 1, the LSI again enters the standby mode when the WDT has counted up to H'80. This standby mode can be canceled by power-on resets.

## 12.3.2 Changing the Frequency

To change the frequency used by the PLL, use the WDT. When changing the frequency only by switching the divider, do not use the WDT.

- 1. Before changing the frequency, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
- 2. Set the type of count clock used in the CKS2 to CKS0 bits of WTCSR and the initial values for the counter in the WTCNT counter. These values should ensure that the time till count overflow is longer than the clock oscillation settling time. This setting does not depend on a value of the WT/IT bit.
- 3. When the frequency control register (FRQCR) is written, the processor stops temporarily. The WDT starts counting.
- 4. When the WDT count overflows, the CPG resumes supplying the clock and the processor resumes operation. The WOVF and IOVF flags in WTCSR are not set when this happens.
- 5. The counter stops at the values H'00.

6. Before changing the WTCNT after the execution of the frequency change instruction, always confirm that the value of the WTCNT is H'00 by reading the WTCNT.

#### 12.3.3 Using Watchdog Timer Mode

- 1. Clear the TME bit of WTCSR to 0. If the TME bit is set to 1, the reset or the interval timer interrupt might be generated by error operation at the counter overflow.
- 2. Set the WT/IT bit in the WTCSR to 1, set the reset type in the RSTS bit, set the type of count clock in the CKS2–CKS0 bits, and set the initial value of the counter in the WTCNT.
- 3. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
- 4. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
- 5. When the counter overflows, the WDT sets the WOVF flag in WTCSR to 1 and generates the type of reset specified by the RSTS bit. The counter then resumes counting.

## 12.3.4 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

- 1. Clear the TME bit of WTCSR to 0. If the TME bit is set to 1, the reset or the interval timer interrupt might be generated by error operation at the counter overflow.
- 2. Clear the WT/IT bit in the WTCSR to 0, set the type of count clock in the CKS2–CKS0 bits, and set the initial value of the counter in the WTCNT.
- 3. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
- 4. When the counter overflows, the WDT sets the IOVF in WTCSR to 1 and an interval timer interrupt request is sent to INTC. The counter then resumes counting.
- 5. To clear the interval timer interrupt request in the exception handling routine, clear the flag which is set in the IOVF bit in WTCSR. For operation of interrupt exception handling, see section 4, Exception Handling and section 8, Interrupt Controller.

# Section 13 Power-Down Modes

This LSI has three types of the power-down modes: sleep mode, software standby mode, and module standby function. In power-down mode, the CPU and some on-chip peripheral modules are halted. The power-down mode is cancelled by reset or interrupt sources.

The power dissipation is decreased in addition by stopping a built-in regulator if internal circuit power VDD(=1.5 V) is supplied from the external power supply.

#### 13.1 Features

- 1. Sleep mode
- 2. Software standby mode
- 3. Module standby function
- 4. VDD (= 1.5 V) can be supplied from the outside with turning off a built-in regulator.

ataSheet4U.com

#### 13.1.1 Power-Down Modes

This LSI supports the following power-down modes and function:

- 1. Sleep mode
- 2. Software standby mode
- 3. Module standby function (cache, X/Y memory, U memory, DMAC, UBC, H-UDI and on-chip peripheral module)\*

Note: \* Also the USBH and USBF have the module standby function. However, the USBH and USBF modules have control functions for their own since their clock sources are different from those for other modules. For details, refer to section 18, USB Pin Multiplex Controller (USBPM).

Table 13.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

On/off of a built-in regulator does not influence the operation of each mode.

**Table 13.1 States of Power-Down Modes** 

					Sta	te			
Mode	Transition Conditions	CPG	CPU	CPU Reg- ister	On-Chip Memory	On-Chip Peripheral Modules	Pins	External Memory	Canceling Procedure
Sleep	Execute SLEEP	Runs	Halts	Held	Halts	Run	Held	Refreshed	1. Interrupt
mode	instruction with STBY bit cleared to 0 in STBCR				(Contents held)			automati- cally	2. Reset
Software		Halts	Halts	Held	Halt	Halt	*	Self-	1. NMI, IRQ
Standby mode	instruction with STBY bit set to 1 in STBCR				(Contents held)			refreshed	2. Reset by RESETP
Module standby function	Set MSTP bit to 1 in STBCR	Runs	Runs	Held	Specified module halts	Specified module halts	Held	Refreshed automatically	1. Clear MSTP bit to 0
DataSheet4					(Contents held)				2. Power- on reset

Notes: \* For details, refer to Appendix, A. Pin States.

This state can be cleared by an emulator using the H-UDI command in ASE mode. For details, refer to the manual on emulator.

#### 13.1.2 Reset

A reset is used at power-on or to re-execute from the initial state. This LSI supports two types of reset: power-on reset and manual reset. In power-on reset, any processing to be currently executed is terminated and any events not executed are canceled to execute reset processing immediately. In manual reset, processing required to maintain external memory contents is continued. The following shows the conditions in which power-on reset or manual reset occurs.

- Power-on reset
  - A. A low level signal is input to the  $\overline{RESETP}$  pin.
  - B. The WDT counter overflows if WDT starts counting while the WT/IT and RSTS bits of the WTCSR are set to 1 and cleared to 0, respectively.
  - C. An H-UDI reset occurs. (For details on H-UDI reset, refer to section 26, User Debugging Interface (H-UDI).)
- Manual reset

The WDT counter overflows if WDT starts counting while the WT/IT and RSTS bits of the WTCSR are set to 1.

# 13.1.3 Input/Output Pins

Table 13.2 shows the pins for the on/off control of a built-in regulator.

**Table 13.2 Pin Configuration** 

	Pin Name	Input/Output	Description
	RESETP	Input	Power-on Reset
			Inputting low level signal to this pin cause a transition to power-on reset processing.
w.D:	TEST_REG	Input	Built-in regulator selection pin. The built-in power supply regulator is used when this pin is high, external power input is used when this pin is low for the internal power (VDD = 1.5 V). The level of this pin should not be changed during operation
	REG_PD_MAIN DataSheet4U.com	Input/NC	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD = 1.5 V). This pin should be open when the built-in power supply regulator is used.
	REG_PD_BGR	Input/NC	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD = 1.5 V). This pin should be open when the built-in power supply regulator is used.
	REG_PD_VREF	Input/NC	Built-in regulator control. This pin should be fixed to high when the external power supply is used for the internal power (VDD = 1.5 V). This pin should be open when the built-in power supply regulator is used.

## 13.2 Register Descriptions

The registers listed below are used in power-down mode. Refer to section 27, List of Registers for the register addresses and register states in each operating mode.

- Standby control register (STBCR)
- Standby control register 2 (STBCR2)
- Standby control register 3 (STBCR3)
- Standby control register 4 (STBCR4)
- Memory clock control register (MCCR)

vww.DataSheet4U.con

## 13.2.1 Standby Control Register (STBCR)

STBCR is an 8-bit readable/writable register that specifies the state of the power-down mode. This register is initialized at power-on reset but retains the previous value after manual reset.

Bit	Bit Name	Initial Value	R/W	Description	
7	STBY	0	R/W	Software Standby	
				Specifies transition to software standby mode.	
				Executing SLEEP instruction puts chip into sleep mode	
				Executing SLEEP instruction puts chip into software standby mode	
6, 5	_	All 0	R	Reserved	
				This bit is always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.	
.Da <u>ł</u> aSheet4	STBXTL	0	R/W	Standby Crystal	
				Specifies whether the crystal oscillator stops or continues in standby mode.	
				0: Stops crystal oscillator in standby mode.	
				1: Continues crystal oscillator in standby mode.	
3	_	0	R	Reserved	
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.	
2	MSTP2	0	R/W	Module Stop 2	
				Halts the clock supply to the timer unit TMU when the MSTP2 bit has been set to 1.	
				0: TMU runs	
				1: Clock supply to TMU halted	
1, 0	_	All 0	R	Reserved	
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.	

## 13.2.2 Standby Control Register 2 (STBCR2)

STBCR2 is a readable/writable 8-bit register that controls the operation of modules in the power-down mode. The STBCR2 register is initialized at power-on reset but retains the previous value after manual reset.

Bit	Bit Name	Initial Value	R/W	Description
7	MSTP10	0	R/W	Module Stop 10
				When the MSTP10 bit is set to 1, the supply of the clock to the H-UDI is halted.
				0: H-UDI runs
				1: Clock supply to H-UDI halted
6	MSTP9	0	R/W	Module Stop 9
				When the MSTP9 bit is set to 1, the supply of the clock to the UBC is halted.
ataSheet	Alloom			0: UBC runs
				1: Clock supply to UBC halted
5	MSTP8	0	R/W	Module Stop 8
				When the MSTP8 bit is set to 1, the supply of the clock to the DMAC is halted.
				0: DMAC runs
				1: Clock supply to DMAC halted
4	MSTP7	0	R/W	Module Stop 7
				When the MSTP7 bit is set to 1, the supply of the clock to the DSP is halted.
				0: DSP runs
				1: Clock supply to DSP halted
3	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
2	MSTP5	0	R/W	Module Stop 5
				When the MSTP5 bit is set to 1, the supply of the clock to the cache memory is halted.
				0: The cache memory runs
				1: Clock supply to the cache memory halted

Bit	Bit Name	Initial Value	R/W	Description
1	MSTP4	0	R/W	Module Stop 4
				When the MSTP4 bit is set to 1, the supply of the clock to the U memory is halted.
				0: The U memory runs
				1: Clock supply to the U memory halted
0	MSTP3	0	R/W	Module Stop 3
				When the MSTP3 bit is set to 1, the supply of the clock to the X/Y memory is halted.
				0: The X/Y memory runs
				1: Clock supply to the X/Y memory halted

## 13.2.3 Standby Control Register 3 (STBCR3)

STBCR3 is an 8-bit readable/writable register that controls the operation of modules in the power-down mode. STBCR3 is initialized at power-on reset but retains the previous value after manual reset.

Bit	Bit Name	Initial Value	R/W	Description
7	MSTP37	0	R/W	Module Stop 37
				When the MSTP37 bit is set to 1, the supply of the clock to the SIOF is halted.
				0: SIOF runs
				1: Clock supply to SIOF halted
6 to 0	_	All 0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

www.DataSheet4U.com

## 13.2.4 Standby Control Register 4 (STBCR4)

STBCR4 is an 8-bit readable/writable register that controls the operation of modules in the power-down mode. STBCR4 is initialized at power-on reset but retains the previous value after manual reset.

7 — 0 R	₹ ₹/W	Reserved This bit is always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
	R/W	always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
	R/W	
6 MSTP46 0 R		Module Stop 46
		When the MSTP46 bit is set to 1, the supply of the clock to the USB is halted.
		0: USB runs
		1: Clock supply to USB halted
DataSheet4U.com		Note: If this bit is set to 1, it can only be cleared by a power-on reset. Even if 0 is written to this bit, it cannot be cleared to 0.
5, 4 — All 0 F	3	Reserved
		This bit is always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
3 MSTP43 0 F	R/W	Module Stop 43
		When the MSTP43 bit is set to 1, the supply of the clock to the BOOT is halted.
		0: BOOT runs
		1: Clock supply to BOOT halted
		Note: When this bit is changed from 1 to 0 (when the supply to the BOOT was in a halted state and then changed to a run state), it takes time until access to the BOOT module is possible. When this bit is changed from 1 to 0, accessing the BOOT module should be made after the STBCR4 register is read to secure a time for warm up.
2 MSTP42 0 F	R/W	Module Stop 42
		When the MSTP42 bit is set to 1, the supply of the clock to the DAC is halted.
		0: DAC runs
		1: Clock supply to DAC halted

Bit	Bit Name	Initial Value	R/W	Description
1	MSTP41	0	R/W	Module Stop 41
				When the MSTP41 bit is set to 1, the supply of the clock to the SCIF1 is halted.
				0: The SCIF1 runs
				1: Clock supply to the SCIF1 halted
0	MSTP40	0	R/W	Module Stop 40
				When the MSTP40 bit is set to 1, the supply of the clock to the SCIF0 is halted.
				0: The SCIF0 runs
				1: Clock supply to the SCIR0 halted

www.DataSheet4U.con

## 13.2.5 Memory Clock Control Register (MCCR)

MCCR is an 8-bit readable/writable register that controls the operation of the memory clock on/off in sleep mode. MCCR is initialized at power-on reset but retains the previous value after manual reset.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	' to 3 — All 0 R		R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
2	UMCLKC	0	R/W	U Memory Clock Control
				Controls the U memory on/off in sleep mode
				0: U memory clock off in sleep mode
				1: U memory clock on in sleep mode
ataSheet4U				When this bit is set to 1, it is possible to access the U memory with DMAC and USBH in sleep mode.
				Note: When changing the clock frequency multiplication ratio, clear UMCLKC bit to 0.  There is the restriction on the interrupt processing when this function is used. Refer to section 7, U Memory for details.
1	XYMCLKC	0	R/W	X/Y Memory Clock Control
				Controls the X/Y memory on/off in sleep mode
				0: X/Y memory clock off in sleep mode
				1: X/Y memory clock on in sleep mode
				When this bit is set to 1, it is possible to access the X/Y memory with DMAC and USBH in sleep mode.
				Note: When changing the clock frequency multiplication ratio, clear XYMCLKC bit to 0. There is the restriction on the interrupt processing when this function is used. Refer to section 6, X/Y Memory for details.
0	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.

## 13.3 Operation

#### 13.3.1 Sleep Mode

#### 1. Transition to Sleep Mode

Executing the SLEEP instruction when the STBY bit in STBCR is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the SLEEP instruction, the contents of its internal registers remain unchanged. The on-chip peripheral modules continue to run in sleep mode and the clock continues to be output to the CKIO pin.

#### 2. Canceling Sleep Mode

Sleep mode is canceled by interrupts (NMI, IRQ, and on-chip peripheral module) or reset. Interrupts are accepted in sleep mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR to the stack before executing the SLEEP instruction.

— Canceling with an Interrupt

www.DataSheeWhen an NMI, IRQ or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. A code indicating the interrupt source is set in the INTEVT2 registers.

Canceling with a Reset
 Sleep mode is canceled by a power-on reset or a manual reset.

### 13.3.2 Software Standby Mode

#### 1. Transition to Software Standby Mode

The LSI switches from a program execution state to a software standby mode by executing the SLEEP instruction when the STBY bit in STBCR register is 1. In software standby mode, not only the CPU but also the clock and on-chip peripheral modules halt. The clock output state from the CKIO pin can be selected by combining the CKOEN bit in the FRQCR register and the HIZCNT bit in the CMNCR register.

The contents of the CPU and cache registers remain unchanged. Some registers of on-chip peripheral modules are, however, initialized. Table 13.3 lists the states of on-chip peripheral module registers in a software standby mode.

RENESAS

Table 13.3 Register States in Software Standby Mode

Module	Registers Initialized	Registers Retaining Data
Interrupt controller (INTC)	_	All registers
Bus state controller (BSC)	_	All registers
DMAC	_	All registers
Clock pulse generator (CPG)	_	All registers
Timer Unit (TMU)	TSTR register	Except TSTR register
SIOF, SCIF0, SCIF1	_	All registers
USBPM, USBH, USBF	_	All registers
D/A converter (DAC)	_	All registers
I/O port	_	All registers
User break controller (UBC)	_	All registers
H-UDI	_	All registers

MAN DataShoot/III.com

The procedure for switching to software standby mode is as follows:

- 1. Clear the TME bit in the WDT's timer control register (WTCSR) to 0 to stop the WDT.
- 2. Set the WDT's timer counter (WTCNT) to 0 and the CKS2 to CKS0 bits in the WTCSR register to appropriate values to secure the specified oscillation settling time.
- 3. After the STBY bit in the STBCR register is set to 1, a SLEEP instruction is executed.

### 2. Canceling Software Standby Mode

Software standby mode is canceled by interrupts (NMI, IRQ) or a reset.

— Canceling with an Interrupt

The on-chip WDT can be used for hot starts. When the chip detects an NMI or IRQ interrupt, the clock will be supplied to the entire chip and software standby mode canceled after the time set in the WDT's timer control/status register has elapsed. Interrupt handling then begins and a code indicating the interrupt source is set in the INTEVT2 registers. After the branch to the interrupt handling routine, clear the STBY bit in the STBCR register. WTD stops automatically. If the STBY bit is not cleared, WTD continues operation and a transition is made to software standby mode\* when the WTCNT reaches H'80. Interrupts are accepted in software standby mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR to the stack before executing the SLEEP instruction.

Immediately after an interrupt is detected, the phase of the CKIO pin clock output may be unstable, until the software standby mode is canceled when the CKOEN bit in the FRQCR register and the HIZCNT bit in the CMNCR register are set to 1.

Note: \* This standby mode can be canceled by the reset from the RESETP pin.

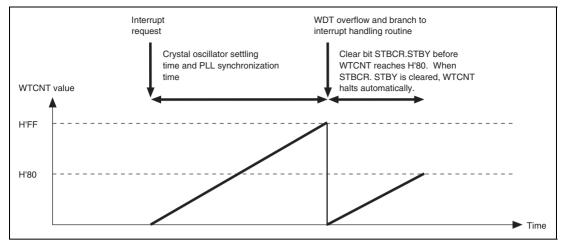

Figure 13.1 Canceling Standby Mode with STBCR.STBY

#### Canceling with a Reset

www.DataSheeSoftware standby mode is canceled by a reset using the  $\overline{RESETP}$  pin. Keep the  $\overline{RESETP}$  pin low until the clock oscillation settles. The internal clock will continue to be output to the CKIO pin except clock operating mode 7.

#### 13.3.3 Module Standby Function

#### 1. Transition to Module Standby Function

Setting the standby control register MSTP bits to 1 halts the supply of clocks to the corresponding on-chip peripheral modules. This function can be used to reduce the power consumption in normal mode as well as sleep mode. The module should be disabled before a transition to the module standby function is made.

In module standby state, the functions of the external pins of the on-chip peripheral modules change depending on the on-chip peripheral module and port settings. Almost all of the register states are the same as those in standby mode. For details, refer to table 13.3.

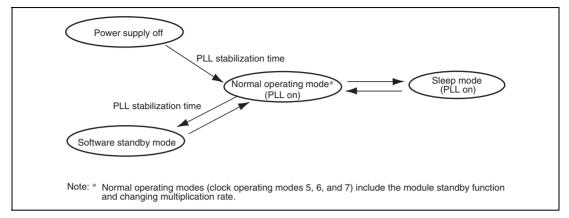

## 2. Canceling Module Standby Function

The module standby function can be canceled by clearing the MSTP bits to 0, or by a poweron reset. To cancel the module standby function by clearing the corresponding MSTP bit to 0, read the MSTP bit to check the MSTP bit was cleared correctly.

#### 13.3.4 State Transitions between Modes

Figure 13.2 shows the transition between modes.

w.DataSheet4U.com

Figure 13.2 Transitions between Modes

#### 13.3.5 Method of turning off the built-in regulator (external VDD used)

The power dissipation of this LSI can be decreased by turning off the built-in regulator if internal power  $V_{DD}$  (= 1.5 V) is supplied from the outside.

When TEST\_REG pin is low, REG\_PD\_MAIN pin, REG\_PD\_BGR pin, and REG\_PD\_VREF pin are high, the built-in regulator is turned off, and then internal power VDD (= 1.5 V) can be supplied from the outside.

As a result, an internal power loss in a built-in regulator can be decreased.

## 13.4 Usage note

## 13.4.1 Reset by the $\overline{RESETP}$ pin

The RDI\_REFCLK\_IN pin should be supplied with some clock input although Renesas RF-IC is not used. The RESETP pin has the function to maintain the reset signal internally during specified clock cycles from RDI\_REFCLK\_IN.

www.DataSheet4U.com

# Section 14 Timer Unit (TMU)

This LSI includes a three-channel 32-bit timer unit (TMU).

#### 14.1 Features

- Each channel is provided with an auto-reload 32-bit down counter
- All the channels are provided with 32-bit constant registers and 32-bit down counters for an auto-reload that can be read or written to at any time
- All the channels generate interrupt requests when the 32-bit down counter underflows (H'00000000 → H'FFFFFFFF)
- Allows selection among 4 counter input clocks: Pφ/4, Pφ/16, Pφ/64, and Pφ/256

Figure 14.1 shows a block diagram of the TMU.

MANA DataShootAll.com

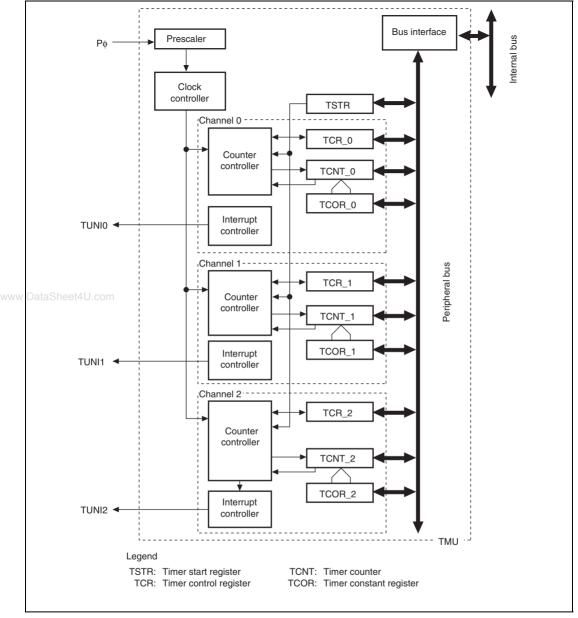

Figure 14.1 TMU Block Diagram

## 14.2 Register Descriptions

The TMU has the following registers. Refer to section 27, List of Registers, for more details of the addresses of these registers and state of these registers in each processor mode. The TMU register names are expressed in the XXX\_N form, with XXX indicating the register name and N indicating the channel number. For example, TCOR\_0 represents the TCOR for channel 0.

- 1. Common
  - Timer start register (TSTR)
- 2. Channel 0
  - Timer constant register\_0 (TCOR\_0)
  - Timer counter\_0 (TCNT\_0)
  - Timer control register 0 (TCR 0)
- 3. Channel 1
  - Timer constant register\_1 (TCOR\_1)
- www.DataSl<del>ree</del>t4Timer.counter\_1 (TCNT\_1)
  - Timer control register\_1 (TCR\_1)
  - 4. Channel 2
    - Timer constant register\_2 (TCOR\_2)
    - Timer counter 2 (TCNT 2)
    - Timer control register\_2 (TCR\_2)

## 14.2.1 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects whether to run or halt the timer counters (TCNT).

		Initial		
Bit	Bit Name	Value	R/W	Description
7 to 3	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
2	STR2	0	R/W	Counter Start 2
				Selects whether to run or halt timer counter 2 (TCNT_2).
				0: TCNT_2 count halted
				1: TCNT_2 counts
1 )ataShee	STR1	0	R/W	Counter Start 1
				Selects whether to run or halt timer counter 1 (TCNT_1).
				0: TCNT_1 count halted
				1: TCNT_1 counts
0	STR0	0	R/W	Counter Start 0
				Selects whether to run or halt timer counter 0 (TCNT_0).
				0: TCNT_0 count halted
				1: TCNT_0 counts

## 14.2.2 Timer Control Registers (TCR)

The TCR registers are 16-bit readable/writable registers that control the timer counters (TCNT) and interrupts.

The TCR registers control the issuance of interrupts when the flag indicating timer counter (TCNT) underflow has been set to 1, and also carry out counter clock selection.

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
8	UNF	0	R/(W)*	Underflow Flag
				Status flag that indicates occurrence of a TCNT underflow.
				0: TCNT has not underflowed
				[Clearing condition]
				0 is written to UNF
				1: TCNT has underflowed
				[Setting condition]
				TCNT underflows
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
5	UNIE	0	R/W	Underflow Interrupt Control
				Controls enabling of interrupt generation when the status flag (UNF) indicating TCNT underflow has been set to 1.
				0: Interrupt due to UNF (TUNI) is disabled
				1: Interrupt due to UNF (TUNI) is enabled
4 to 2	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
1	TPSC1	0	R/W	Timer Prescaler 1 and 0
0	TPSC0	0	R/W	Select the TCNT count clock.
				00: Count on Pφ/4
				01: Count on Pφ/16
				10: Count on Pφ/64
				11: Count on Po/256

Note: \* Only 0 can be written for flag clearing.

#### **14.2.3** Timer Constant Registers (TCOR)

The TCOR registers set the value to be set in TCNT when TCNT underflows.

The TCOR registers are 32-bit readable/writable registers. Their initial value is H'FFFFFFF.

#### 14.2.4 Timer Counters (TCNT)

TCNT counts down upon input of a clock. The clock input is selected using the TPSC1 and TPSC0 bits in the timer control register (TCR).

When a TCNT count-down results in an underflow (H'00000000  $\rightarrow$  H'FFFFFFF), the underflow flag (UNF) in the timer control register (TCR) of the relevant channel is set. The TCOR value is simultaneously set in TCNT itself and the count-down continues from that value.

Initial value of the TCNT is H'FFFFFFF.

MAN DataShoot/III con

## 14.3 Operation

Each of the three channels has a 32-bit timer counter (TCNT) and a 32-bit timer constant register (TCOR). The TCNT counts down. The auto-reload function enables synchronized counting.

#### 14.3.1 Counter Operation

When the STR0-STR2 bits in the timer start register (TSTR) are set to 1, the corresponding timer counter (TCNT) starts counting. When a TCNT underflows, the UNF flag of the corresponding timer control register (TCR) is set. At this time, if the UNIE bit in TCR is 1, an interrupt request is sent to the CPU. Also at this time, the value is copied from TCOR to TCNT and the down-count operation is continued.

# 1. Count Operation Setting Procedure

An example of the procedure for setting the count operation is shown in figure 14.2.

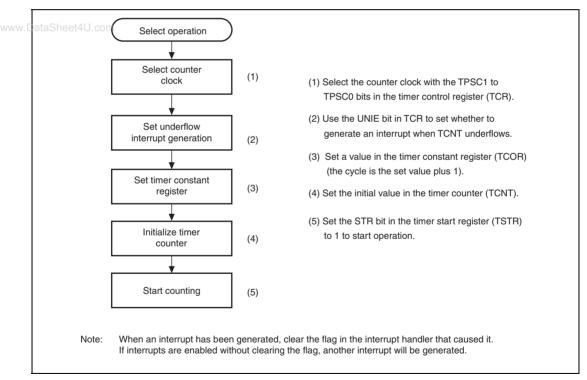

Figure 14.2 Setting Count Operation

### 2. Auto-Reload Count Operation

Figure 14.3 shows the TCNT auto-reload operation.

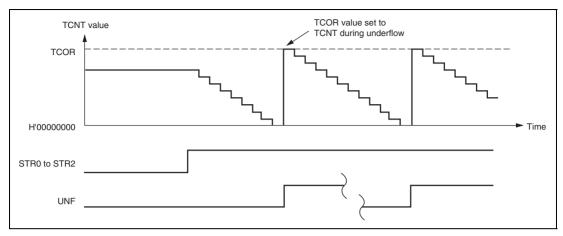

Figure 14.3 Auto-Reload Count Operation

#### 3. TCNT Count Timing

Set the TPSC1 and TPSC0 bits in TCR to select one of the four internal clocks ( $P\phi/4$ ,  $P\phi/16$ ,  $P\phi/64$ ,  $P\phi/256$ ) that is created by dividing the peripheral module clock. Figure 14.4 shows the timing.

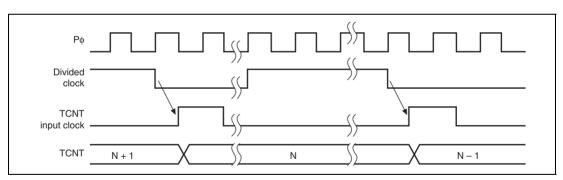

Figure 14.4 Count Timing when Internal Clock Is Operating

## 14.4 Interrupts

There is one source of TMU interrupts: underflow interrupts (TUNI).

### 14.4.1 Status Flag Set Timing

The UNF bit is set to 1 when the TCNT underflows. Figure 14.5 shows the timing.

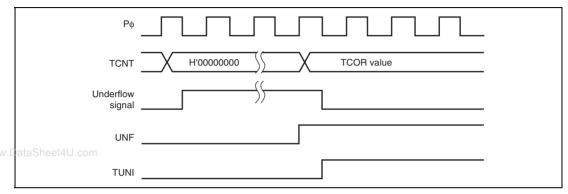

Figure 14.5 UNF Set Timing

## 14.4.2 Status Flag Clear Timing

The status flag can be cleared by writing 0 from the CPU. Figure 14.6 shows the timing.

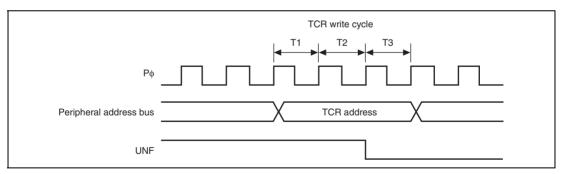

Figure 14.6 Status Flag Clear Timing

#### 14.4.3 Interrupt Sources and Priorities

The TMU produces underflow interrupts for each channel. When the interrupt request flag and interrupt enable bit are both set to 1, the interrupt is requested. Codes are set in the interrupt event register 2 (INTEVT2) for these interrupts and interrupt processing occurs according to the codes.

The relative priorities of channels can be changed using the interrupt controller (see section 4, Exception Handling, and section 8, Interrupt Controller (INTC)). Table 14.1 lists TMU interrupt sources.

**Table 14.1 TMU Interrupt Sources** 

Channel	Interrupt Source	Description	Priority
0	TUNI0	Underflow interrupt 0	High
1	TUNI1	Underflow interrupt 1	
2	TUNI2	Underflow interrupt 2	Low

www DataSheet4LL com

## 14.5 Usage Notes

**Writing to Registers:** Synchronization processing is not performed for timer counting during register writes. When writing to registers, always clear the appropriate start bits for the channel (STR2 to STR0) in the timer start register (TSTR) to halt timer counting.

**Reading Registers:** Synchronization processing is performed for timer counting during register reads. When timer counting and register read processing are performed simultaneously, the register value before TCNT counting down (with synchronization processing) is read.

# Section 15 Serial I/O with FIFO (SIOF)

This LSI includes a clock-synchronized serial I/O module with FIFO (SIOF)(Serial Input/Output with FIFO). The SIOF can perform serial communication with a serial peripheral interface bus (SPI).

#### 15.1 Features

Serial transfer

16-stage 32-bit FIFOs (transmission is independent)

Supports 8-bit data/16-bit data/16-bit stereo audio output

MSB first for data transmission

Supports a maximum of 48-kHz sampling rate

Synchronization by either frame synchronization pulse or left/right channel switch

Supports CODEC control data interface

Connectable to linear, audio, or A-Law or  $\mu$ -Law CODEC chip

Supports both master and slave modes

Serial clock

An external pin input or internal clock ( $P\phi$ ) can be selected as the clock source.

- Interrupts: One type
- DMA transfer

Supports DMA transfer by a transfer request for transmission

SPI mode

Fixed master mode can perform the full-duplex communication with the SPI slave devices continuously.

Selects the falling/rising edge of the SCK as data sampling.

Selects the clock phase of the SCK as a transmit timing.

Selects three slave devices.

The length of transmit/receive data is fixed to 8 bits.

Figure 15.1 shows a block diagram of the SIOF.

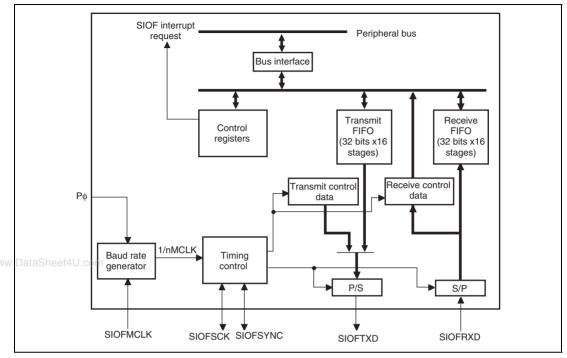

Figure 15.1 Block Diagram of SIOF

## 15.2 Input/Output Pins

The pin configuration in this module is shown in table 15.1.

**Table 15.1 Pin Configuration** 

Pin Name	Abbreviation*	I/O	Function
SIOF_MCLK	SIOFMCLK	Input	Master clock input
SIOF_SCK	SIOFSCK (SCK)	I/O	Serial clock (common to transmission/reception)
(SCK)			In SPI mode, fixed to output.
SIOF_SYNC (SIOF_SS0)	SIOFSYNC (SSO)	I/O	Frame synchronous signal (common to transmission/reception)
			In SPI mode, fixed to output, and selects slave device 0.
SIOF_SS1	(SS1)	Output	In SPI mode, selects slave device 1.
SIOF_SS2	(SS2)	Output	In SPI mode, selects slave device 2.
SIOF_TXD (MOSI)	SIOFTXD (MOSI)	Output	Transmit data
SIOF_RXD (MISO)	SIOFRXD (MISO)	Input	Receive data

Note:

<sup>\*</sup> The pins are collectively called SIOFMCLK, SIOFSCK, SIOFSYNC, SIOFTXD, and SIOFRXD in the following descriptions. In SPI mode, the pins are called SCK, SSO, SS1, SS2, MOSI, and MISO.

## 15.3 Register Descriptions

The SIOF has the following registers. For the addresses of these registers and the register states in each operating state, refer to section 27, List of Registers.

- Mode register (SIMDR)
- Control register (SICTR)
- Transmit data register (SITDR)
- Receive data register (SIRDR)
- Transmit control data register (SITCR)
- Receive control data register (SIRCR)
- Status register (SISTR)
- Interrupt enable register (SIIER)
- FIFO control register (SIFCTR)
- Clock select register (SISCR)
- www.Deta Transmit data assign register (SITDAR)
  - Receive data assign register (SIRDAR)
  - Control data assign register (SICDAR)
  - SPI control register (SPICR)

### 15.3.1 Mode Register (SIMDR)

SIMDR is a 16-bit readable/writable register that sets the SIOF operating mode.

Bit	Bit Name	Initial Value	R/W	Description
15	TRMD1	1	R/W	Transfer Mode
14	TRMD0	0	R/W	Select transfer mode as shown in table 15.2.
				00: Slave mode 1
				01: Slave mode 2
				10: Master mode 1
				11: Master mode 2
13	SYNCAT	0	R/W	SIOFSYNC Pin Valid Timing
				Indicates the position of the SIOFSYNC signal to be output as a synchronization pulse.
				0: At the start-bit data of frame
				1: At the last-bit data of slot

Bit	Bit Name	Initial Value	R/W	Description
12	REDG	0	R/W	Receive Data Sampling Edge
				<ol> <li>The SIOFRXD signal is sampled at the falling edge of SIOFSCK. (The SIOFTXD signal is output at the rising edge of SIOFSCK).</li> </ol>
				<ol> <li>The SIOFRXD signal is sampled at the rising edge of SIOFSCK. (The SIOFTXD signal is output at the falling edge of SIOFSCK).</li> </ol>
				Note: This bit is valid only in master mode.
11	FL3	0	R/W	Frame Length
10	FL2	0	R/W	00xx: Data length is 8 bits and frame length is 8 bits.
9	FL1	0	R/W	0100: Data length is 8 bits and frame length is 16 bits.
8	FL0	0	R/W	0101: Data length is 8 bits and frame length is 32 bits.
				0110: Data length is 8 bits and frame length is 64 bits.
	4411			0111: Data length is 8 bits and frame length is 128 bits.
	t4U.com			10xx: Data length is 16 bits and frame length is 16 bits.
				1100: Data length is 16 bits and frame length is 32 bits.
				1101: Data length is 16 bits and frame length is 64 bits.
				1110: Data length is 16 bits and frame length is 128 bits.
				1111: Data length is 16 bits and frame length is 256 bits.
				Note: When data length is specified as 8 bits, control data cannot be transmitted or received.
				x: Don't care
7	TXDIZ	0	R/W	SIOFTXD Pin Output when Transmission is Invalid*
				0: High output (1 output) when invalid
				1: High-impedance state when invalid
				Note: Invalid means when disabled, and when a slot that is not assigned as transmit data or control data is being transmitted.
6	RCIM	0	R/W	Receive Control Data Interrupt Mode
				<ol><li>Sets the RCRDY bit in SISTR when the contents of SIRCR change.</li></ol>
				Sets the RCRDY bit in SISTR each time when the SIRCR receives the control data.

Bit	Bit Name	Initial Value	R/W	Description
5	SYNCAC	0	R/W	SIOFSYNC Pin Polarity
				Valid when the SIOFSYNC signal is output as synchronous pulse in master mode.
				0: Active-high
				1: Active-low
4	SYNCDL	0	R/W	Data Pin Bit Delay for SIOFSYNC Pin
				Valid when the SIOFSYNC signal is output as synchronous pulse. Only one-bit delay is valid for transmission in slave mode.
				0: No bit delay
				1: 1-bit delay
3 to 0	_	All 0	R	Reserved
	4U.com			These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation cannot be guaranteed.

Table 15.2 shows the operation in each transfer mode.

**Table 15.2 Operation in Each Transfer Mode** 

Transfer Mode	Master/Slave	SIOFSYNC	Bit Delay	Control Data Method*
Slave mode 1	Slave	Synchronous pulse	SYNCDL bit	Slot position
Slave mode 2	Slave	Synchronous pulse	_	Secondary FS
Master mode 1	Master	Synchronous pulse	_	Slot position
Master mode 2	Master	L/R	No	Not supported

Note: \* The control data method is valid only when the FL bit is specified as 1xxx. (x: Don't care)

## 15.3.2 Control Register (SICTR)

SICTR is a 16-bit readable/writable register that sets the SIOF operating state.

		Initial		
Bit	Bit Name	Value	R/W	Description
15	SCKE	0	R/W	Serial Clock Output Enable
				This bit is valid in master mode.
				0: Disables the SIOFSCK output (outputs 0)
				1: Enables the SIOFSCK output
				If this bit is set to 1, the SIOF initializes the baud rate generator and initiates the operation. At the same time, the SIOF outputs the clock generated by the baud rate generator to the SIOFSCK pin.
				This bit is initialized in module stop mode.
14 ataSheet4U.	FSE	0	R/W	Frame Synchronous Signal Output Enable
				This bit is valid in master mode.
				0: Disables the SIOFSYNC output (outputs 0)
				1: Enables the SIOFSYNC output
				<ul> <li>If this bit is set to 1, the SIOF initializes the frame counter and initiates the operation.</li> </ul>
				This bit is initialized in module stop mode.
13 to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
9	TXE	0	R/W	Transmit Enable
				0: Disables data transmission from the SIOFTXD pin
				1: Enables data transmission from the SIOFTXD pin
				<ul> <li>This bit setting becomes valid at the start of the next frame (at the rising edge of the SIOFSYNC signal).</li> <li>When the 1 setting for this bit becomes valid, the SIOF issues a transmit transfer request according to the setting of the TFWM bit in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the SIOFTXD pin begins.</li> <li>This bit is initialized upon a transmit reset.</li> <li>This bit is initialized in module stop mode.</li> </ul>
8	RXE	0	R/W	Receive Enable
				<ul> <li>0: Disables data reception from SIOFRXD</li> <li>1: Enables data reception from SIOFRXD</li> <li>This bit setting becomes valid at the start of the next frame (at the rising edge of the SIOFSYNC signal).</li> <li>When the 1 setting for this bit becomes valid, the SIOF begins the reception of data from the SIOFRXD pin. When receive data is stored in the receive FIFO, the SIOF issues a reception transfer request according to the setting of the RFWM bit in SIFCTR.</li> <li>This bit is initialized upon receive reset.</li> <li>This bit is initialized in module stop mode.</li> </ul>
7 to 2	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
1	TXRST	0	R/W	Transmit Reset
				0: Does not reset transmit operation
				1: Resets transmit operation
				<ul> <li>This bit setting becomes valid immediately. This bit should be cleared to 0 before setting the register to be initialized.</li> </ul>
				<ul> <li>When the 1 setting for this bit becomes valid, the SIOF immediately sets transmit data from the SIOFTXD pin to 1, and initializes the transmit data register and transmit-related status. The following are initialized.</li> </ul>
				— SITDR
				— SITCR
v.DataSheet	4U.com			Transmit FIFO write pointer
				— TCRDY, TFEMP, and TDREQ bits in SISTR
				This bit is automatically cleared by SIOF after completes a reset, to be always read as 0.
0	RXRST	0	R/W	Receive Reset
				0: Does not reset receive operation
				1: Resets receive operation
				<ul> <li>This bit setting becomes valid immediately. This bit should be cleared to 0 before setting the register to be initialized.</li> </ul>
				<ul> <li>When the 1 setting for this bit becomes valid, the SIOF immediately disables reception from the SIOFRXD pin, and initializes the receive data register and receive-related status. The following are initialized.</li> <li>— SIRDR</li> <li>— SIRCR</li> <li>— Receive FIFO read pointer</li> </ul>
				<ul> <li>RCRDY, RFFUL, and RDREQ bits in SISTR</li> </ul>
				This bit is automatically cleared by SIOF after completes a reset, to be always read as 0.

## 15.3.3 Transmit Data Register (SITDR)

SITDR is a 32-bit write-only register that specifies the SIOF transmit data.

SITDR is initialized by the conditions specified in section 27, List of Registers, or by a transmit reset caused by the TXRST bit in SICTR.

SITDR is initialized in module stop mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	SITDL15 to SITDL0	All 0	W	Left-Channel Transmit Data
				Specify data to be output from the SIOFTXD pin as left-channel data. The position of the left-channel data in the transmit frame is specified by the TDLA bit in SITDAR.
				These bits are valid only when the TDLE bit in
ataSheet4	U.com			SITDAR is set to 1.
15 to 0	SITDR15 to SITDR0	All 0	W	Right-Channel Transmit Data
				Specify data to be output from the SIOFTXD pin as right-channel data. The position of the right-channel data in the transmit frame is specified by the TDRA bit in SITDAR.
				<ul> <li>These bits are valid only when the TDRE bit and TLREP bit in SITDAR are set to 1 and cleared to 0, respectively.</li> </ul>

## 15.3.4 Receive Data Register (SIRDR)

SIRDR is a 32-bit read-only register that reads receive data of the SIOF. SIRDR stores data in the receive FIFO and is initialized by the conditions specified in section 27, List of Registers, or by a receive reset caused by the RXRST bit in SICTR.

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	6 SIRDL15 to SIRDL 0	All 0	R	Left-Channel Receive Data
				Store data received from the SIOFRXD pin as left- channel data. The position of the left-channel data in the receive frame is specified by the RDLA bit in SIRDAR.
				These bits are valid only when the RDLE bit in
				SIRDAR is set to 1.
15 to 0	SIRDR15	All 0	R	Right-Channel Receive Data
ataSheet4U	SIRDR 0			Store data received from the SIOFRXD pin as right-channel data. The position of the right-channel data in the receive frame is specified by the RDRA bit in SIRDAR.
				• These bits are valid only when the RDRE bit in SIRDAR is set to 1.

### 15.3.5 Transmit Control Data Register (SITCR)

SITCR is a 32-bit readable/writable register that specifies transmit control data of the SIOF. SITCR can be specified only when the FL bit in SIMDR is specified as 1xxx (x: Don't care).

SITCR is initialized by the conditions specified in section 27, List of Registers, or by a transmit reset caused by the TXRST bit in SICTR.

SITCR is initialized in module stop mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	SITC015 to SITC00	All 0	R/W	Control Channel 0 Transmit Data
				Specify data to be output from the SIOFTXD pin as control channel 0 transmit data. The position of the control channel 0 data in the transmit or receive frame is specified by the CD0A bit in SICDAR.
ataSheet4				These bits are valid only when the CD0E bit in
				SICDAR is set to 1.
15 to 0	SITC115 to SITC10	All 0	R/W	Control Channel 1 Transmit Data
				Specify data to be output from the SIOFTXD pin as control channel 1 transmit data. The position of the control channel 1 data in the transmit or receive frame is specified by the CD1A bit in SICDAR.
				• These bits are valid only when the CD1E bit in SICDAR is set to 1.

## 15.3.6 Receive Control Data Register (SIRCR)

SIRCR is a 32-bit readable/writable register that stores receive control data of the SIOF. SIRCR can be specified only when the FL bit in SIMDR is specified as 1xxx (x: Don't care).

SIRCR is initialized by the conditions specified in section 27, List of Registers, or by a receive reset caused by the RXRST bit in SICTR.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	SIRC015 to SIRC00	All 0	R/W	Control Channel 0 Receive Data
				Store data received from the SIOFRXD pin as control channel 0 receive data. The position of the control channel 0 data in the transmit or receive frame is specified by the CD0A bit in SICDAR.
				These bits are valid only when the CD0E bit in
to Classical III	4000			SICDAR is set to 1.
15 to 0	SIRC115 to SIRC10	All 0	R/W	Control Channel 1 Receive Data
				Store data received from the SIOFRXD pin as control channel 1 receive data. The position of the control channel 1 data in the transmit or receive frame is specified by the CD1A bit in SICDAR.
				<ul> <li>These bits are valid only when the CD1E bit in SICDAR is set to 1.</li> </ul>

## 15.3.7 Status Register (SISTR)

SISTR is a 16-bit read-only register that shows the SIOF state. Each bit in this register becomes an SIOF interrupt source when the corresponding bit in SIIER is set to 1.

SISTR is initialized in module stop mode.

		Initial		
Bit	Bit Name	Value	R/W	Description
15	_	0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, the operation is not guaranteed.
14	TCRDY	0	R	Transmit Control Data Ready
				0: Indicates that a write to SITCR is disabled
				1: Indicates that a write to SITCR is enabled
DataSheet4U.com				<ul> <li>If SITCR is written when this bit is cleared to 0, SITCR is over-written and the previous contents of SITCR are not output from the SIOFTXD pin.</li> </ul>
				• This bit is valid when the TXE bit in SITCR is set to 1.
				<ul> <li>This bit indicates a state of the SIOF. If SITCR is written, the SIOF clears this bit.</li> </ul>
				<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>
13	TFEMP	0	R	Transmit FIFO Empty
				0: Indicates that transmit FIFO is not empty
				1: Indicates that transmit FIFO is empty
				This bit is valid when the TXE bit in SICTR is 1.
				• This bit indicates a state; if SITDR is written, the SIOF clears this bit.
				If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.

		Initial		
Bit	Bit Name	Value	R/W	Description
12	TDREQ	0	R	Transmit Data Transfer Request
				<ol> <li>Indicates that the size of empty space in the transmit FIFO does not exceed the size specified by the TFWM bit in SIFCTR.</li> </ol>
				<ol> <li>Indicates that the size of empty space in the transmit FIFO exceeds the size specified by the TFWM bit in SIFCTR.</li> </ol>
				A transmit data transfer request is issued when the empty space in the transmit FIFO exceeds the size specified by the TFWM bit in SIFCTR.
				When using transmit data transfer through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when conditions for setting this bit are satisfied, the SIOF again indicates 1 for this bit.
				• This bit is valid when the TXE bit in SICTR is 1.
	4U.com			<ul> <li>This bit indicates a state; if the size of empty space in the transmit FIFO is less than the size specified by the TFWM bit in SIFCTR, the SIOF clears this bit.</li> </ul>
				<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>
11	_	0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to this bit, the operation is not guaranteed.
10	RCRDY	0	R	Receive Control Data Ready
				0: Indicates that the SIRCR stores no valid data.
				1: Indicates that the SIRCR stores valid data.
				<ul> <li>If SIRCR is written when this bit is set to 1, SIRCR is modified by the latest data.</li> </ul>
				• This bit is valid when the RXE bit in SICTR is set to 1.
				<ul> <li>This bit indicates a state of the SIOF. If SIRCR is read, the SIOF clears this bit.</li> </ul>
				If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.

Bit	Bit Name	Initial Value	R/W	Description
9	RFFUL	0	R	Receive FIFO Full
				0: Receive FIFO not full
				1: Receive FIFO full
				This bit is valid when the RXE bit in SICTR is 1.
				<ul> <li>This bit indicates a state; if SIRDR is read, the SIOF clears this bit.</li> </ul>
				<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>
8	RDREQ	0	R	Receive Data Transfer Request
				0: Indicates that the size of valid space in the receive FIFO does not exceed the size specified by the RFWM bit in SIFCTR.
	eet4U.com			<ol> <li>Indicates that the size of valid space in the receive FIFO exceeds the size specified by the RFWM bit in SIFCTR.</li> </ol>
				A receive data transfer request is issued when the valid space in the receive FIFO exceeds the size specified by the RFWM bit in SIFCTR.
				When using receive data transfer through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when conditions for setting this bit are satisfied, the SIOF again indicates 1 for this bit.
				This bit is valid when the RXE bit in SICTR is 1.
				<ul> <li>This bit indicates a state; if the size of valid space in the receive FIFO is less than the size specified by the RFWM bit in SIFCTR, the SIOF clears this bit.</li> </ul>
				<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

		Initial		
Bit	Bit Name	Value	R/W	Description
5	SAERR	0	R/W	Slot Assign Error
				0: Indicates that no slot assign error occurs
				1: Indicates that a slot assign error occurs
				A slot assign error occurs when the specifications in SITDAR, SIRDAR, and SICDAR overlap.
				If a slot assign error occurs, the SIOF does not transmit data to the SIOFTXD pin and does not receive data from the SIOFRXD pin. Note that the SIOF does not clear the TXE bit or RXE bit in SICTR at a slot assign error.
				• This bit is valid when the TXE bit or RXE bit in SICTR is 1.
				• When 1 is written to this bit, the contents are cleared.
				If the issue of interrupts by this bit is enabled, an
				SIOF interrupt is issued.
DataSheet4	UFSERR	0	R/W	Frame Synchronization Error
				0: Indicates that no frame synchronization error occurs
				1: Indicates that a frame synchronization error occurs
				A frame synchronization error occurs when the next frame synchronization timing appears before the previous data or control data transfers have been completed.
				If a frame synchronization error occurs, the SIOF performs transmission or reception for slots that can be transferred.
				<ul> <li>This bit is valid when the TXE or RXE bit in SICTR is</li> <li>1.</li> </ul>
				<ul> <li>When 1 is written to this bit, the contents are cleared.</li> <li>Writing 0 to this bit is invalid.</li> </ul>
				If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.

	Bit	Bit Name	Initial Value	R/W	Description
-	3	TFOVF	0	R/W	Transmit FIFO Overflow
					0: No transmit FIFO overflow
					1: Transmit FIFO overflow
					A transmit FIFO overflow means that there has been an attempt to write to SITDR when the transmit FIFO is full.
					When a transmit FIFO overflow occurs, the SIOF indicates overflow, and writing is invalid.
					• This bit is valid when the TXE bit in SICTR is 1.
					• When 1 is written to this bit, the contents are cleared.
					Writing 0 to this bit is invalid.
					If the issue of interrupts by this bit is enabled, an
					SIOF interrupt is issued.
	2	TFUDF	0	R/W	Transmit FIFO Underflow
		4U.com			0: No transmit FIFO underflow
					1: Transmit FIFO underflow
					A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty.
					When a transmit FIFO underflow occurs, the SIOF repeatedly sends the previous transmit data.
					• This bit is valid when the TXE bit in SICTR is 1.
					<ul> <li>When 1 is written to this bit, the contents are cleared.</li> <li>Writing 0 to this bit is invalid.</li> </ul>
					If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.
-	1	RFUDF	0	R/W	Receive FIFO Underflow
					0: No receive FIFO underflow
					1: Receive FIFO underflow
					A receive FIFO underflow means that reading of SIRDR has occurred when the receive FIFO is empty.
					When a receive FIFO underflow occurs, the value of data read from SIRDR is not guaranteed.
					• This bit is valid when the RXE bit in SICTR is 1.
					• When 1 is written to this bit, the contents are cleared.
					Writing 0 to this bit is invalid.
					<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>
-					www.DataSheet4U.com

		Initial		
Bit	Bit Name	Value	R/W	Description
0	RFOVF	0	R/W	Receive FIFO Overflow
				0: No receive FIFO overflow
				1: Receive FIFO overflow
				A receive FIFO overflow means that writing has occurred when the receive FIFO is full.
				When a receive FIFO overflow occurs, the SIOF indicates overflow, and receive data is lost.
				This bit is valid when the RXE bit in SICTR is 1.
				<ul> <li>When 1 is written to this bit, the contents are cleared.</li> <li>Writing 0 to this bit is invalid.</li> </ul>
				<ul> <li>If the issue of interrupts by this bit is enabled, an SIOF interrupt is issued.</li> </ul>

# 15.3.8 Interrupt Enable Register (SIIER)

SIIER is a 16-bit readable/writable register that enables the issue of SIOF interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the SIOF issues an interrupt.

		Initial		
Bit	Bit Name	Value	R/W	Description
15	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable
				Transmits an interrupt as an interrupt to the CPU/DMA transfer request. The TDREQE bit can be set as transmit interrupts.
				0: Used as a CPU interrupt
				1: Used as a DMA transfer request to the DMAC
14	TCRDYE	0	R/W	Transmit Control Data Ready Enable
				0: Disables interrupts due to transmit control data ready
				1: Enables interrupts due to transmit control data ready
13	TFEMPE	0	R/W	Transmit FIFO Empty Enable
				0: Disables interrupts due to transmit FIFO empty
				1: Enables interrupts due to transmit FIFO empty

Bit	Bit Name	Initial Value	R/W	Description
12	TDREQE	0	R/W	Transmit Data Transfer Request Enable
				Disables interrupts due to transmit data transfer requests
				Enables interrupts due to transmit data transfer requests
11	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable
				Transmits an interrupt as an interrupt to the CPU/DMA transfer request. The RDREQE bit can be set as receive interrupts.
				0: Used as a CPU interrupt
				1: Used as a DMA transfer request to the DMAC
10	RCRDYE	0	R/W	Receive Control Data Ready Enable
				0: Disables interrupts due to receive control data ready
NataSho	ot4lloom			1: Enables interrupts due to receive control data ready
9	RFFULE	0	R/W	Receive FIFO Full Enable
				0: Disables interrupts due to receive FIFO full
				1: Enables interrupts due to receive FIFO full
8	RDREQE	0	R/W	Receive Data Transfer Request Enable
				<ol> <li>Disables interrupts due to receive data transfer requests</li> </ol>
				<ol> <li>Enables interrupts due to receive data transfer requests</li> </ol>
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.
5	SAERRE	0	R/W	Slot Assign Error Enable
				0: Disables interrupts due to slot assign error
				1: Enables interrupts due to slot assign error
4	FSERRE	0	R/W	Frame Synchronization Error Enable
				0: Disables interrupts due to frame synchronization error
				1: Enables interrupts due to frame synchronization error
3	TFOVFE	0	R/W	Transmit FIFO Overflow Enable
				0: Disables interrupts due to transmit FIFO overflow
				1: Enables interrupts due to transmit FIFO overflow

Bit	Bit Name	Initial Value	R/W	Description
2	TFUDFE	0	R/W	Transmit FIFO Underflow Enable
				0: Disables interrupts due to transmit FIFO underflow
				1: Enables interrupts due to transmit FIFO underflow
1	RFUDFE	0	R/W	Receive FIFO Underflow Enable
				0: Disables interrupts due to receive FIFO underflow
				1: Enables interrupts due to receive FIFO underflow
0	RFOVFE	0	R/W	Receive FIFO Overflow Enable
				0: Disables interrupts due to receive FIFO overflow
				1: Enables interrupts due to receive FIFO overflow

## 15.3.9 FIFO Control Register (SIFCTR)

SIFCTR is a 16-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit	Bit Name	Initial Value	R/W	Description
15	TFWM2	0	R/W	Transmit FIFO Watermark
14	TFWM1	0	R/W	000: Issue a transfer request when 16 stages of the
13	TFWM0	0	R/W	transmit FIFO are empty.
				001: Setting prohibited
				010: Setting prohibited
				011: Setting prohibited
				100: Issue a transfer request when 12 or more stages of the transmit FIFO are empty.
				101: Issue a transfer request when 8 or more stages of the transmit FIFO are empty.
				110: Issue a transfer request when 4 or more stages of the transmit FIFO are empty.
				111: Issue a transfer request when 1 or more stages of transmit FIFO are empty.
				<ul> <li>A transfer request to the transmit FIFO is issued by the TDREQE bit in SISTR.</li> </ul>
				<ul> <li>The transmit FIFO is always used as 16 stages of the FIFO regardless of these bit settings.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
12	TFUA4	1	R	Transmit FIFO Usable Area
11	TFUA3	0	R	Indicate the number of words that can be transferred by
10	TFUA2	0	R	the CPU or DMAC as B'00000 (full) to B'10000 (empty).
9	TFUA1	0	R	
8	TFUA0	0	R

## 15.3.10 Clock Select Register (SISCR)

SISCR is a 16-bit readable/writable register that sets the serial clock generation conditions for the master clock. SISCR can be specified when the TRMD1 and TRMD0 bits in SIMDR are specified as B'10 or B'11.

Bit	Bit Name	Initial Value	R/W	Description
15	MSSEL	1	R/W	Master Clock Source Selection
				Uses the input signal of the SIOFMCLK pin as the master clock
				1: Uses Pφ as the master clock
				The master clock is the clock input to the baud rate generator.
14	MSIMM	1	R/W	Master Clock Direct Selection
taSheet4				0: Uses the output clock of the baud rate generator as the serial clock
				1: Uses the master clock itself as the serial clock
13	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, the operation is not guaranteed.
12	BRPS4	0	R/W	Prescaler Setting
11	BRPS3	0	R/W	Set the master clock division ratio according to the count
10	BRPS2	0	R/W	value of the prescaler of the baud rate generator.
9	BRPS1	0	R/W	The range of settings is from B'00000 ( $\times$ 1/1) to B'11111 ( $\times$ 1/32).
8	BRPS0	0	R/W	(× 1/32).
7 to 3	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
2	BRDV2	0	R/W	Baud Rate Generator's Division Ratio Setting
1	BRDV1	0	R/W	Set the frequency division ratio for the output stage of the
0	BRDV0	0	R/W	baud rate generator.
				000: Prescaler output $\times$ 1/2
				001: Prescaler output × 1/4
				010: Prescaler output × 1/8
				011: Prescaler output × 1/16
				100: Prescaler output × 1/32
				101: Setting prohibited
				110: Setting prohibited
				111: Prescaler output × 1/1*
				The final frequency division ratio of the baud rate generator is determined by BRPS $\times$ BRDV (maximum 1/1024).
				Note: *This setting is valid only when the BRPS4 to BRPS0 bits are set to B'00000.

## 15.3.11 Transmit Data Assign Register (SITDAR)

SITDAR is a 16-bit readable/writable register that specifies the position of the transmit data in a frame (slot number).

Bit	Bit Name	Initial Value	R/W	Description	
15	TDLE	0	R/W	Transmit Left-Channel Data Enable	
				0: Disables left-channel data transmission	
				1: Enables left-channel data transmission	
14 to 12	_	All 0	R	Reserved	
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.	
11	TDLA3	0	R/W	Transmit Left-Channel Data Assigns 3 to 0	
10	TDLA2	0	R/W	Specify the position of left-channel data in a transmit	
9	TDLA1	0	R/W	frame as B'0000 (0) to B'1110 (14).	
8	TDLA0	0	R/W	1111: Setting prohibited	
				<ul> <li>Transmit data for the left channel is specified in the SITDL bit in SITDR.</li> </ul>	

www.DataSheet4U.com

			Initial

0	)	TDRA0	0	R/W	1111: Setting prohibited		
					<ul> <li>Transmit data for the right channel is specified in the SITDR bit in SITDR.</li> </ul>		

## 15.3.12 Receive Data Assign Register (SIRDAR)

SIRDAR is a 16-bit readable/writable register that specifies the position of the receive data in a frame (slot number).

Bit	Bit Name	Initial Value	R/W	Description
15	RDLE	0	R/W	Receive Left-Channel Data Enable
				0: Disables left-channel data reception
				1: Enables left-channel data reception
14 to 12	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

		Initial		
Bit	Bit Name	Value	R/W	Description
11	RDLA3	0	R/W	Receive Left-Channel Data Assign
10	RDLA2	0	R/W	Specify the position of left-channel data in a receive
9	RDLA1	0	R/W	frame as B'0000 (0) to B'1110 (14).
8	RDLA0	0	R/W	1111: Setting prohibited
				<ul> <li>Receive data for the left channel is stored in the SIRDL bit in SIRDR.</li> </ul>
7	RDRE	0	R/W	Receive Right-Channel Data Enable
				0: Disables right-channel data reception
				1: Enables right-channel data reception
6 to 4	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.
3 DataSheet	RDRA3	0	R/W	Receive Right-Channel Data Assign
2	RDRA2	0	R/W	Specify the position of right-channel data in a receive
1	RDRA1	0	R/W	frame as B'0000 (0) to B'1110 (14).
0	RDRA0	0	R/W	1111: Setting prohibited
				<ul> <li>Receive data for the right channel is stored in the SIRDR bit in SIRDR.</li> </ul>

## 15.3.13 Control Data Assign Register (SICDAR)

SICDAR is a 16-bit readable/writable register that specifies the position of the control data in a frame (slot number). SICDAR can be specified only when the FL bit in SIMDR is specified as 1xxx (x: Don't care).

Bit	Bit Name	Initial Value	R/W	Description
15	CD0E	0	R/W	Control Channel 0 Data Enable
				Disables transmission and reception of control channel 0 data
				Enables transmission and reception of control channel 0 data
14 to 12	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

www.DataSheet4U.com

Bit	Bit Name	Initial Value	R/W	Description
11	CD0A3	0	R/W	Control Channel 0 Data Assign
10	CD0A2	0	R/W	Specify the position of control channel 0 data in a receive
9	CD0A1	0	R/W	or transmit frame as B'0000 (0) to B'1110 (14).
8	CD0A0	0	R/W	1111: Setting prohibited
				<ul> <li>Transmit data for the control channel 0 data is specified in the SITD0 bit in SITCR.</li> </ul>
				<ul> <li>Receive data for the control channel 0 data is stored in the SIRD0 bit in SIRCR.</li> </ul>
7	CD1E	0	R/W	Control Channel 1 Data Enable
				0: Disables transmission and reception of control channel 1 data
				Enables transmission and reception of control channel     data
6 to 4		All 0	R	Reserved
	et4U.com			These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.
3	CD1A3	0	R/W	Control Channel 1 Data Assign
2	CD1A2	0	R/W	Specify the position of control channel 1 data in a receive
1	CD1A1	0	R/W	or transmit frame as B'0000 (0) to B'1110 (14).
0	CD1A0	0	R/W	1111: Setting prohibited
				<ul> <li>Transmit data for the control channel 1 data is specified in the SITD1 bit in SITCR.</li> </ul>
				<ul> <li>Receive data for the control channel 1 data is stored in the SIRD1 bit in SIRCR.</li> </ul>

# 15.3.14 SPI Control Register (SPICR)

SPICR is a 16-bit readable/writable register that specifies the operating mode of the SPI.

Bit	Bit Name	Initial Value	R/W	Description
15	SPIM	0	R/W	SPI Mode
				Selects the SIOF operating mode.
				0: Operates as the SIOF.
				1: The SIOF operates in master mode of the SPI.
14	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, the operation is not guaranteed.
13	СРНА	0	R/W	SPI Clock Phase
				Selects the SPI clock phase.
				0: Samples data at the first edge of the SCK.
				1: Samples data at the second edge of the SCK.
12	CPOL	0	R/W	SPI Clock Polarity
				Selects the SPI clock polarity.
				0: The SCK is high-active, and goes low in the idle state.
				1: The SCK is low-active, and goes high in the idle state.
11	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, the operation is not guaranteed.
10	SS2E*	0	R/W	Slave Device 2 (SS2) Enable
				0: Not select slave device 2.
				1: Selects slave device 2.
9	SS1E*	0	R/W	Slave Device 1 (SS1) Enable
				0: Not select slave device 1.
				1: Selects slave device 1.
8	SS0E*	0	R/W	Slave Device 0 (SS0) Enable
				0: Not select slave device 0.
				1: Selects slave device 0.
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, the operation is not guaranteed.

# 15.4 Operation

#### 15.4.1 Serial Clocks

Master/Slave Modes: The following 2 modes are available as the SIOF clock mode.

• Slave mode: SIOFSCK, SIOFSYNC input

• Master mode: SIOFSCK, SIOFSYNC output

**Baud Rate Generator:** In SIOF master mode, the baud rate generator (BRG) is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

Figure 15.2 shows connections for supply of the serial clock.

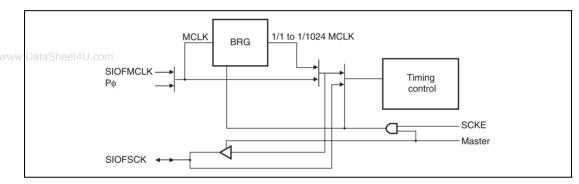

Figure 15.2 Serial Clock Supply

Table 15.3 shows an example of serial clock frequency.

Table 15.3 SIOF Serial Clock Frequency

		Sampling Rai	e	
Frame Length	8 kHz	44.1 kHz	48 kHz	
32 bits	256 kHz	1.4112 MHz	1.536 MHz	
64 bits	512 kHz	2.8224 MHz	3.072 MHz	
128 bits	1.024 MHz	5.6448 MHz	6.144 MHz	
256 bits	2.048 MHz	11.289 MHz	12.289 MHz	

### 15.4.2 Serial Timing

**SIOFSYNC:** The SIOFSYNC is a frame synchronous (FS) signal. Depending on the transfer mode, it has the following two functions.

- Synchronous pulse: 1-bit-width pulse indicating the start of the frame
- L/R: 1/2-frame-width pulse indicating the left-channel stereo data (L) in high level and the right-channel stereo data (R) in low level

Figure 15.3 shows the SIOFSYNC synchronization timing.

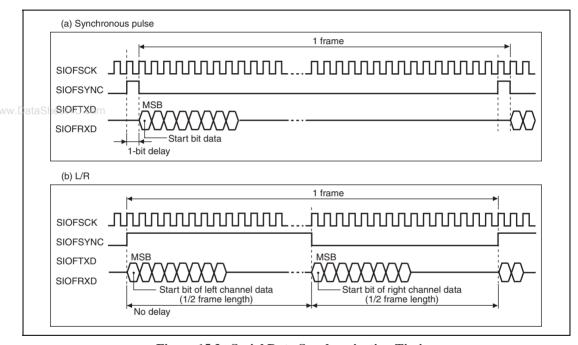

Figure 15.3 Serial Data Synchronization Timing

**Transmit/Receive Timing:** The SIOFTXD transmit timing and SIOFRXD receive timing relative to the SIOFSCK can be set as the sampling timing in the following two ways. The transmit/receive timing is set using the REDG bit in SIMDR.

- Falling-edge sampling
- Rising-edge sampling

Figure 15.4 shows the transmit/receive timing.

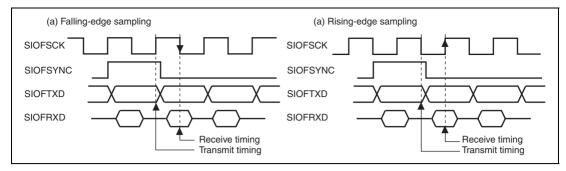

Figure 15.4 SIOF Transmit/Receive Timing

### 15.4.3 Transfer Data Format

The SIOF performs the following transfer.

- Transmit/receive data: Transfer of 8-bit data/16-bit data/16-bit stereo data
- Control data: Transfer of 16-bit data (uses the specific register as interface)

**Transfer Mode:** The SIOF supports the following four transfer modes as listed in table 15.4. The transfer mode can be specified by the TRMD1 and TRMD0 bits in SIMDR.

**Table 15.4 Serial Transfer Modes** 

Transfer Mode	SIOFSYNC	Bit Delay	Control Data
Slave mode 1	Synchronous pulse	SYNCDL bit	Slot position
Slave mode 2	Synchronous pulse		Secondary FS
Master mode 1	Synchronous pulse		Slot position
Master mode 2	L/R	No	Not supported

**Frame Length:** The length of the frame to be transferred by the SIOF is specified by the FL3 to FL0 bits in SIMDR. Table 15.5 shows the relationship between the FL3 to FL0 bit settings and frame length.

Table 15.5 Frame Length

FL3 to FL0	Slot Length	Number of Bits in a Frame	Transfer Data
00xx	8	8	8-bit monaural data
0100	8	16	8-bit monaural data
0101	8	32	8-bit monaural data
0110	8	64	8-bit monaural data
0111	8	128	8-bit monaural data
10xx	16	16	16-bit monaural data
1100	16	32	16-bit monaural/stereo data
1101	16	64	16-bit monaural/stereo data
1110 ataSheet4U.com	16	128	16-bit monaural/stereo data
1111	16	256	16-bit monaural/stereo data

Note: x: Don't care

**Slot Position:** The SIOF can specify the position of transmit data, receive data, and control data in a frame (common to transmission and reception) by slot numbers. The slot number of each data is specified by the following registers.

Transmit data: SITDARReceive data: SIRDARControl data: SICDAR

Only 16-bit data is valid for control data. In addition, control data is always assigned to the same slot number both in transmission and reception.

## 15.4.4 Register Allocation of Transfer Data

**Transmit/Receive Data:** Writing and reading of transmit/receive data is performed for the following registers.

- Transmit data writing: SITDR (32-bit access)
- Receive data reading: SIRDR (32-bit access)

Figure 15.5 shows the transmit/receive data and the SITDR and SIRDR bit alignment.

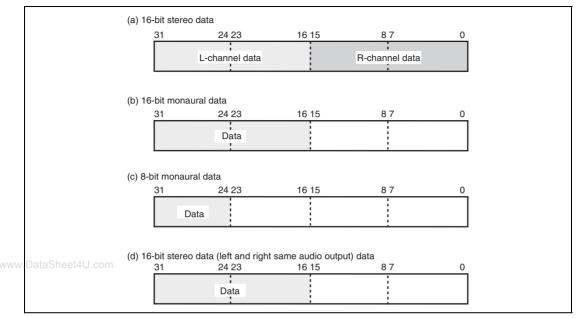

Figure 15.5 Transmit/Receive Data Bit Alignment

Note: In the figure, only the shaded areas are transmitted or received as valid data. Therefore, access must be made in byte units for 8-bit data, and in word units for 16-bit data. Data in unshaded areas is not transmitted or received.

Monaural or stereo can be specified for transmit data by the TDLE bit and TDRE bit in SITDAR. Monaural or stereo can be specified for receive data by the RDLE bit and RDRE bit in SIRDAR. To achieve left and right same audio output while stereo is specified for transmit data, specify the TLREP bit in SITDAR. Tables 15.6 and 15.7 show the audio mode specification for transmit data and that for receive data, respectively.

Table 15.6 Audio Mode Specification for Transmit Data

		Bit		
Mode	TDLE	TDRE	TLREP	
Monaural	1	0	х	
Stereo	1	1	0	
Left and right same audio output	1	1	1	

RENESAS

Note: x: Don't care

www.DataSheet4U.com

**Table 15.7 Audio Mode Specification for Receive Data** 

		Bit	
Mode	RDLE	RDRE	
Monaural	1	0	
Stereo	1	1	

Note: Left and right same audio mode is not supported in receive data.

To execute 8-bit monaural transmission or reception, use the left channel.

**Control Data:** Control data is written to or read from by the following registers.

• Transmit control data write: SITCR (32-bit access)

• Receive control data read: SIRCR (32-bit access)

Figure 15.6 shows the control data and bit alignment in SITCR and SIRCR.

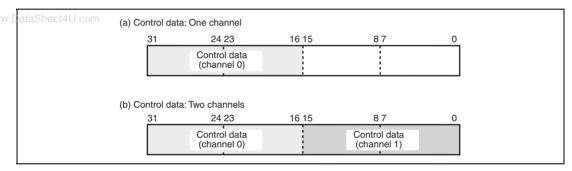

Figure 15.6 Control Data Bit Alignment

The number of channels in control data is specified by the CD0E and CD1E bits in SICDAR. Table 15.8 shows the relationship between the number of channels in control data and bit settings.

Table 15.8 The Number of Channels in Control Data Setting

	DIL		
Number of Channels	CD0E	CD1E	
1	1	0	
2	1	1	

D:4

Note: To use only one channel in control data, use channel 0.

#### 15.4.5 Control Data Interface

Control data performs control command output to the CODEC and status input from the CODEC. The SIOF supports the following two control data interface methods.

- Control by slot position
- Control by secondary FS

Control data is valid only when data length is specified as 16 bits.

**Control by Slot Position (Master Mode 1, Slave Mode 1):** Control data is transferred for all frames transmitted or received by the SIOF by specifying the slot position of control data. This method can be used in both SIOF master and slave modes. Figure 15.7 shows an example of the control data interface timing by slot position control.

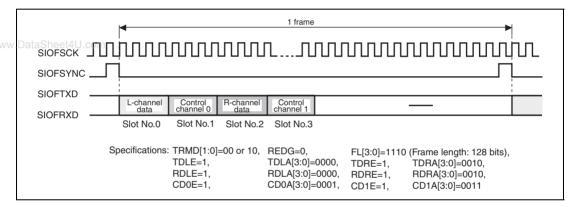

Figure 15.7 Control Data Interface (Slot Position)

Control by Secondary FS (Slave Mode 2): The CODEC normally outputs the SIOFSYNC signal as synchronization pulse (FS). In this method, the CODEC outputs the secondary FS specific to the control data transfer after 1/2 frame time has been passed (not the normal FS output timing) to transmit or receive control data. This method is valid for SIOF slave mode. The following summarizes the control data interface procedure by the secondary FS.

- Transmit normal transmit data of LSB = 0 (the SIOF forcibly clears 0).
- To execute control data transmission, send transmit data of LSB = 1 (the SIOF forcibly set to 1 by writing SITCDR).
- The CODEC outputs the secondary FS.
- The SIOF transmits or receives (stores in SIRCDR) control data (data specified by SITCDR) synchronously with the secondary FS.

Figure 15.8 shows an example of the control data interface timing by the secondary FS.

www.DataSheet4U.com

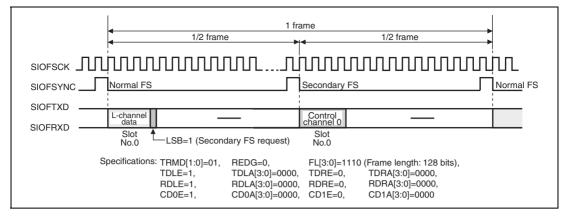

Figure 15.8 Control Data Interface (Secondary FS)

#### 15.4.6 FIFO

**Overview:** The transmit and receive FIFOs of the SIOF have the following features.

- 16-stage 32-bit FIFOs for transmission and reception
- The FIFO pointer can be updated in one read or write cycle regardless of access size of the CPU and DMAC. (One-stage 32-bit FIFO access cannot be divided into multiple accesses.)

**Transfer Request:** The transfer request of the FIFO can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (transmit interrupt source)
- FIFO receive request: RDREQ (receive interrupt source)

The request conditions for FIFO transmit or receive can be specified individually. The request conditions for the FIFO transmit and receive are specified by the TFWM2 to TFWM0 bits and RFWM2 to RFWM0 bits in SIFCTR, respectively. Tables 15.9 and 15.10 summarize the conditions specified by SIFCTR.

Table 15.9 Conditions to Issue Transmit Request

TFWM2 to TFWM0	Number of Requested Stages	Transmit Request	Used Areas
000	1	Empty area is 16 stages	Smallest
100	4	Empty area is 12 stages or more	_ ↑
101	8	Empty area is 8 stages or more	_
110	12	Empty area is 4 stages or more	_ ★
111	16	Empty area is 1 stage or more	Largest

**Table 15.10 Conditions to Issue Receive Request** 

RFWM2 to RFWM0	Number of Requested Stages	Receive Request	Used Areas
000	1	Valid data is 1 stage or more	Smallest
100	4	Valid data is 4 stages or more	_ †
101	8	Valid data is 8 stages or more	_
110	12	Valid data is 12 stages or more	
111	16	Valid data is 16 stages	Largest

The number of stages of the FIFO is always sixteen even if the data area or empty area exceeds the FIFO size (the number of FIFOs). Accordingly, an overflow error or underflow error occurs if data area or empty area exceeds sixteen FIFO stages. The FIFO transmit or receive request is canceled when the above condition is not satisfied even if the FIFO is not empty or full.

**Number of FIFOs:** The number of FIFO stages used in transmission and reception is indicated by www. The following register.

- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA4 to TFUA0 bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA4 to RFUA0 bits in SIFCTR.

The above indicate possible data numbers that can be transferred by the CPU or DMAC.

### 15.4.7 Transmit and Receive Procedures

**Transmission in Master Mode:** Figure 15.9 shows an example of settings and operation for master mode transmission.

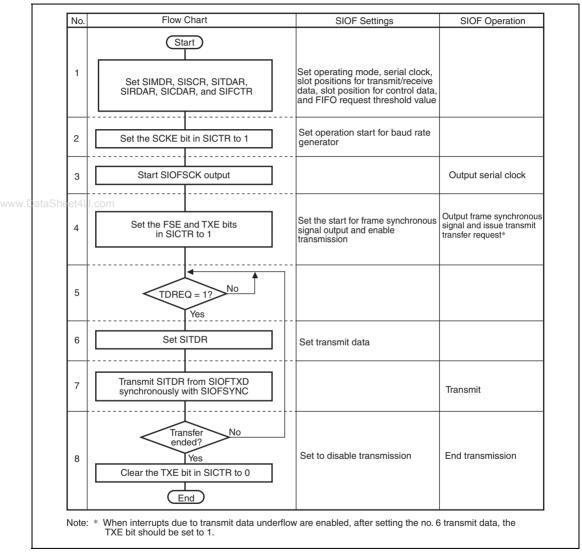

Figure 15.9 Example of Transmit Operation in Master Mode

**Reception in Master Mode:** Figure 15.10 shows an example of settings and operation for master mode reception.

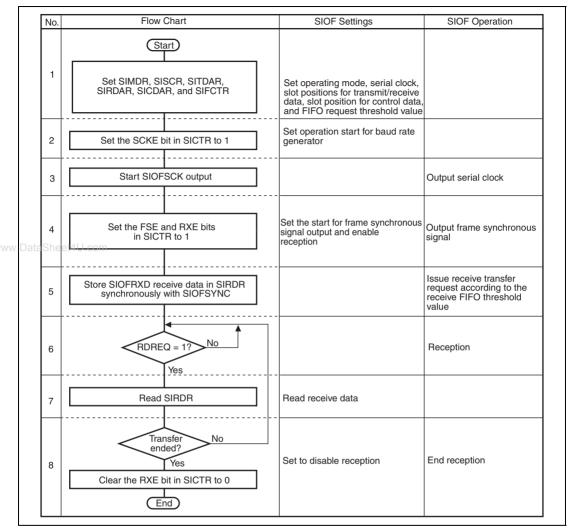

Figure 15.10 Example of Receive Operation in Master Mode

**Transmission in Slave Mode:** Figure 15.11 shows an example of settings and operation for slave mode transmission.

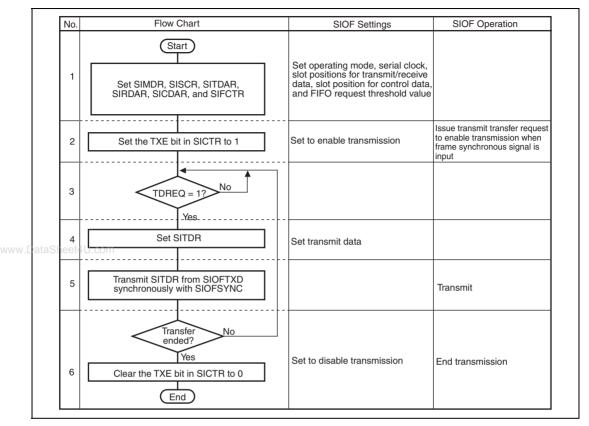

Figure 15.11 Example of Transmit Operation in Slave Mode

**Reception in Slave Mode:** Figure 15.12 shows an example of settings and operation for slave mode reception.

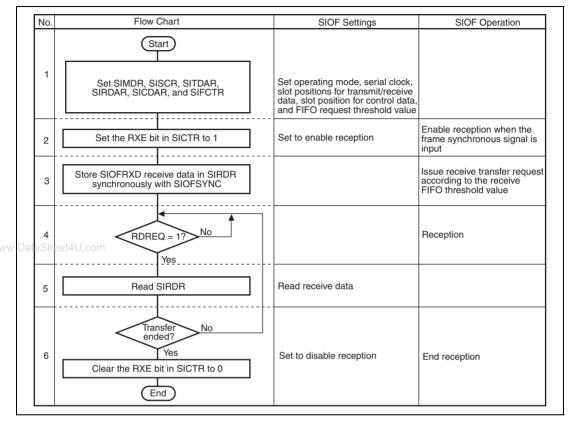

Figure 15.12 Example of Receive Operation in Slave Mode

**Transmit/Receive Reset:** The SIOF can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 15.11 shows the details of initialization upon transmit or receive reset.

**Table 15.11 Transmit and Receive Reset** 

Туре	Objects Initialized		
Transmit reset	SITDR		
	Transmit FIFO write pointer		
	TCRDY, TFEMP, and TDREQ bits in SISTR		
	TXE bit in SICTR		
Receive reset	SIRDR		
	Receive FIFO read pointer		
	RCRDY, RFFUL, and RDREQ bits in SISTR		
	RXE bit in SICTR		

**Module Stop Mode:** The SIOF stops the transmit/receive operation in module stop mode. Then the following contents are initialized.

- SITDR
- SITCR
- Read pointer of receive FIFO
- Write pointer of transmit FIFO
- SISTR
- SICTR

### 15.4.8 Interrupts

The SIOF has one type of interrupt.

**Interrupt Sources:** Interrupts can be issued by several sources. Each source is shown as an SIOF status in SISTR. Table 15.12 lists the SIOF interrupt sources.

**Table 15.12 SIOF Interrupt Sources** 

	No.	Classification	Bit Name	Function Name	Description
	1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO stores data of specified size or more.
	2	•	TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
	3	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
	4	•	RFFUL	Receive FIFO full	The receive FIFO is full.
/.D	<b>5</b> alaSh	Control	TCRDY	Transmit control data ready	The transmit control register is ready to be written.
	6		RCRDY	Receive control data ready	The receive control data register stores valid data.
	7	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
	8		TFOVF	Transmit FIFO overflow	Write to the transmit FIFO is performed while the transmit FIFO is full.
	9	•	RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
	10	•	RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
	11	•	FSERR	FS error	A synchronous signal is input before the specified bit number has been passed (in slave mode).
	12	•	SAERR	Slot assign error	The same slot is specified in both serial data and control data.

Whether an interrupt is issued or not as the result of an interrupt source is determined by the SIIER settings. If an interrupt source is set to 1 and the corresponding bit in SIIER is set to 1, an SIOF interrupt issued.

**Regarding Transmit and Receive Classification:** The transmit sources and receive sources are signals indicating the state; after being set, if the state changes, they are automatically cleared by the SIOF.

When the DMA transfer is used, a DMA transfer request is pulled low (0 level) for one cycle at the end of DMA transfer.

**Processing when Errors Occur:** On occurrence of each of the errors indicated as a status in SISTR, the SIOF performs the following operations.

- Transmit FIFO underflow (TFUDF)
  - The immediately preceding transmit data is again transmitted.
- Transmit FIFO overflow (TFOVF)
  - The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  - Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  - An undefined value is output on the bus.
- FS error (FSERR)
  - The internal counter is reset according to the FSYN signal in which an error occurs.
- Slot assign error (SAERR)
  - If the same slot is assigned to both serial data and control data, the slot is assigned to serial data.
  - If the same slot is assigned to two control data items, data cannot be transferred correctly.

### 15.4.9 Transmit and Receive Timing

Examples of the SIOF serial transmission and reception are shown in figure 15.13 through figure 15.20

**8-bit Monaural Data (1):** Synchronous pulse method, falling edge sampling, slot No.0 used for transmit and receive data, a frame length = 8 bits

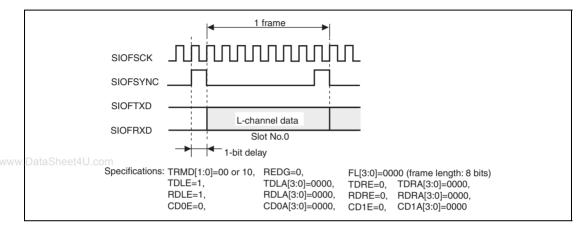

Figure 15.13 Transmit and Receive Timing (8-Bit Monaural Data (1))

**8-bit Monaural Data (2):** Synchronous pulse method, falling edge sampling, slot No.0 used for transmit and receive data, and frame length = 16 bits

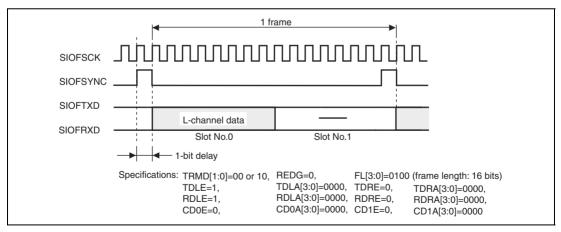

Figure 15.14 Transmit and Receive Timing (8-Bit Monaural Data (2))

**16-bit Monaural Data (1):** Synchronous pulse method, falling edge sampling, slot No.0 used for transmit and receive data, and frame length = 64 bits

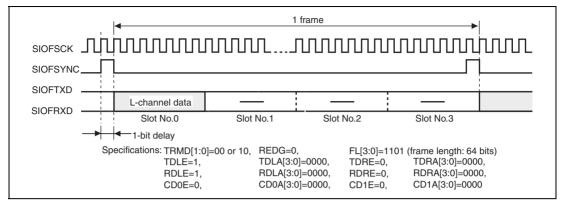

Figure 15.15 Transmit and Receive Timing (16-Bit Monaural Data (1))

**16-bit Stereo Data (1):** L/R method, rising edge sampling, slot No.0 used for left channel data, slot No.1 used for right channel data, and frame length = 32 bits

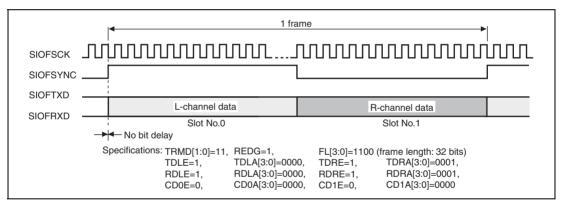

Figure 15.16 Transmit and Receive Timing (16-Bit Stereo Data (1))

**16-bit Stereo Data (2):** L/R method, rising edge sampling, slot No.0 used for left-channel transmit data, slot No.1 used for left-channel receive data, slot No.2 used for right-channel transmit data, slot No.3 used for right-channel receive data, and frame length = 64 bits

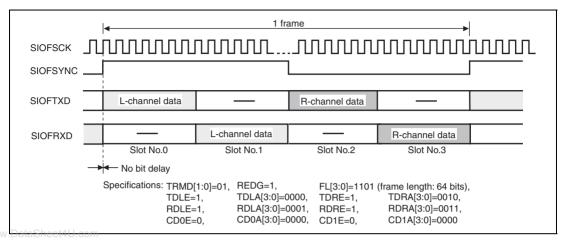

Figure 15.17 Transmit and Receive Timing (16-Bit Stereo Data (2))

**16-bit Stereo Data (3):** Synchronous pulse method, falling edge sampling, slot No.0 used for left-channel data, slot No.1 used for right-channel data, slot No.2 used for control channel 0 data, slot No.3 used for control channel 1 data, and frame length = 128 bits

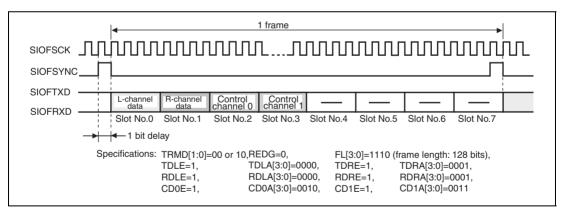

Figure 15.18 Transmit and Receive Timing (16-Bit Stereo Data (3))

**16-bit Stereo Data (4):** Synchronous pulse method, falling edge sampling, slot No.0 used for left-channel data, slot No.2 used for right-channel data, slot No.1 used for control channel 0 data, slot No.3 used for control channel 1 data, and frame length = 128 bits

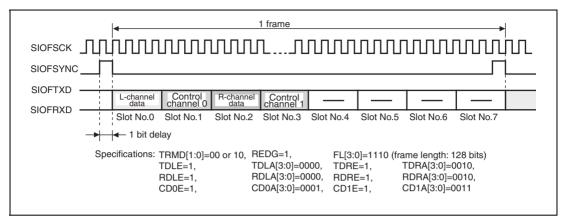

Figure 15.19 Transmit and Receive Timing (16-Bit Stereo Data (4))

**Synchronization-Pulse Output Mode at End of Each Slot (SYNCAT Bit = 1):** Synchronous pulse method, falling edge sampling, slot No.0 used for left-channel data, slot No.1 used for right-channel data, slot No.2 used for control channel 0 data, slot No.3 used for control channel 1 data, and frame length = 128 bits

In this mode, valid data must be set to slot No. 0.

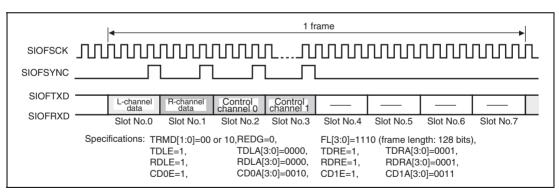

Figure 15.20 Transmit and Receive Timing (16-Bit Stereo Data)

#### 15.4.10 SPI Mode

SPI-mode operation is selected for the SIOF by the setting in SPICR.

**Example of Configuration:** Figure 15.21 shows an example of the configuration for SPI-mode communications.

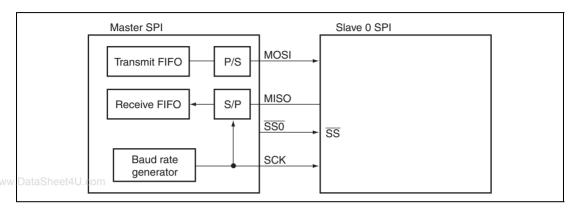

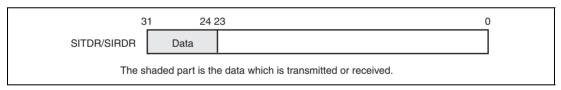

Figure 15.21 Example of Configuration in SPI Mode

**SPI Operation:** The states of operation in SPI mode are described in terms of transmission and reception in table 15.13. In SPI mode, the data length is fixed to 8 bits and the values of the upper 8 bits of SITDR and SIRDR are the valid data for transmission and reception, respectively.

The only sources of interrupts that should be enabled in SPI-mode transfer are transmit data transfer request (TDREQ), transmit FIFO empty (TFEMP), receive-data transfer request (RDREQ), receive-FIFO full (RFFUL), and receive-FIFO overflow (RFOVF). Enabled or disabled states are selectable by the interrupt enable register (SIIER). Interrupts from other sources must be disabled at all times.

For the DMA transfer requests, the enabled sources are transmit-data DMA transfer request (TDMA) and receive-data DMA transfer request (RDMA). Enabled or disabled states are selectable by the interrupt enable register (SIIER).

In SPI mode, the baud rate is set by SISCR.

Table 15.13 States of Transmit and Receive Operations in SPI Mode

TXE	RXE	TDMAE	RDMAE	SPI Transmit/Receive Operation
0	0	Don't care	Don't care	Transmission/reception is disabled
0	1	0	1	Half-Duplex Reception
				The transmit FIFO does not operate and dummy data is transmitted from the MOSI. Data received at the MISO is stored in the receive FIFO and is transferred by using the DMA.
				Receive operation continues as long as RE bit = 1; the receive-FIFO overflow (RFOVF) status is set after the receive FIFO has become full and further receive data is ignored.
1	0	0	0	Half-Duplex Transmission
	et4U.com			The data in the transmit FIFO is transmitted from the MOSI. The receive FIFO does not operate, and data on the MISO is ignored. When the transmit FIFO becomes empty, the transmit operation is completed.
		1	0	Half-Duplex Transmission
				The data which has been transferred by using the DMA to the transmit FIFO is transmitted from the MOSI. The receive FIFO does not operate and data on the MISO is ignored. When the transmit FIFO becomes empty, the transmit operation is completed.
1	1	0	0	Full-Duplex Communication
				The transmit and receive FIFOs operate at the same time. Data in the transmit FIFO are transmitted or received. When there is no data left in the transmit FIFO, the transmit and receive operations are completed.

Note: In SPI mode, settings other than the above are prohibited.

In half-duplex reception (transmission is disabled), the value output from the MOSI can be controlled by the TXDIZ bit in SIMDR as follows.

TXDIZ = 0: Transmission is disabled, 1 is output on the MOSI.

TXDIZ = 1: Transmission is disabled, the MOSI is in the high-impedance state.

**Serial Clock Timing:** Timing on the data and clock lines in SPI mode is shown in figures 15.22 and 15.23. The user can select from four serial transfer formats, which differ according to the phase and polarity of the serial clock.

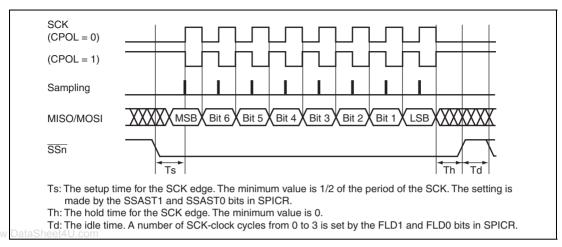

Figure 15.22 SPI Data/Clock Timing 1 (CPHA = 0)

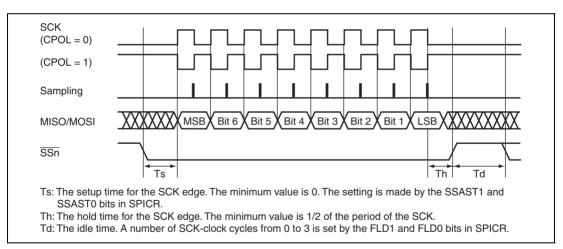

Figure 15.23 SPI Data/Clock Timing 2 (CPHA = 1)

# 15.5 Usage Notes

- The transitions to the software standby mode and module standby mode should not be made by setting the module standby bit of the SIOF during data reception and transmission. The transitions to software standby mode and module standby mode should be made after both TXE and RXE bits in the SICTR register have been cleared (transmission/reception disabled).
- 2. The SIOFTXD pin in SIOF is output pin even when the TXE bit is cleared. The SIOFRXD pin is in the input enabled state even when the RXE bit is cleared. In software standby mode, the SIOFTXD pin is high-impedance and the SIOFRXD pin is fixed to input disable state. Note that the SIOFTXD pin is multiplexed with the port PTA1 and its initial settings after a power-on reset are an input pin and the pull-up MOS is on. The SIOFRXD pin is multiplexed with the port PTA2, and the initial settings after a power-on reset are an input pin and the pull-up MOS is on. Care is required on dealing the signal lines that are connected to the SIOFTXD and SIOFRXD pins.
- 3. The SIOF has some 32-bit registers that handle two pieces of independent 16-bit data. Note that the order of upper word and lower word on the memory may be switched within the register in a data transfer with above registers when switching the big endian and little endian by using the MD5 pin.
- 4. When the SIOF is set as a transfer destination or transfer source, a transfer is carried out only in longword units.

www.DataSheet4U.con

# Section 16 Serial Communication Interface with FIFO (SCIF)

This LSI has a two-channel serial communication interface with on-chip FIFO buffers (Serial Communication Interface with FIFO: SCIF). The SCIF can perform asynchronous and clock synchronous serial communication.

64-stage FIFO registers are provided for both transmission and reception, enabling fast, efficient, and continuous communication.

#### 16.1 Features

• Asynchronous mode

Serial data communication is executed using an asynchronous system in which synchronization is achieved character by character. Serial data communication can be carried out with standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA).

There is a choice of eight serial data communication formats.

— Data length: 7 or 8 bits

— Stop bit length: 1 or 2 bits

— Parity: Even/odd/none

— LSB-first transfer

- Receive error detection: Parity, framing, and overrun errors
- Break detection: If a framing error is followed by at least one frame at the space "0" (low) level, a break is detected.
- Clock synchronous mode

Serial data communication is synchronized with a clock. Serial data communication can be carried out with other chips that have a synchronous communication function.

- Data length: 8 bits
- LSB-first transfer
- Full-duplex communication capability

The transmitter and receiver are independent units, enabling transmission and reception to be performed simultaneously.

The transmitter and receiver both have a 64-stage FIFO buffer structure, enabling fast and continuous serial data transmission and reception.

- On-chip baud rate generator allows any bit rate to be selected.
- Choice of serial clock source: internal clock from baud rate generator or external clock from SCK pin.

www.DataSheet4U.com

Rev. 1.00, 02/04, page 435 of 804

- Six interrupt sources in asynchronous mode
   There are six interrupt sources—transmit-data-stop, transmit-FIFO-data-empty, receive-FIFO-data-full, receive-error (framing/parity error), break-receive, and receive-data-ready interrupts.

   The vectors of each interrupt are the same.
- Two interrupt sources in clock synchronous mode
   There are two interrupt sources—transmit-FIFO-data-empty and receive-FIFO-data-full interrupts. The vectors of each interrupt are the same.
- The DMA controller (DMAC) can be activated to execute a data transfer in the event of a transmit-FIFO-data-empty, transmit-data-stop, or receive-FIFO-data-full interrupt. The DMAC requests of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.
- On-chip modem control functions ( $\overline{CTS}$  and  $\overline{RTS}$ )
- On-chip transmit-data-stop functions (only in asynchronous mode)
- When not in use, the SCIF can be stopped by halting its clock supply to reduce power consumption.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in the receive data in the receive FIFO register can be ascertained.

Figure 16.1 shows a block diagram of the SCIF.

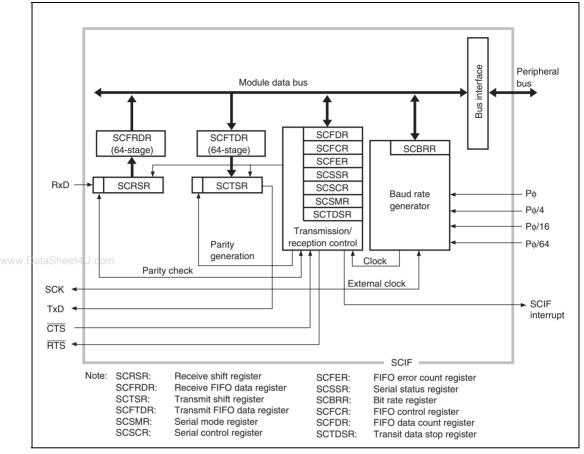

Figure 16.1 Block Diagram of SCIF

# 16.2 Input/Output Pins

Table 16.1 shows the SCIF pin configuration.

**Table 16.1 Pin Configuration** 

	Channel	Pin Name	Abbreviation*1	I/O	Function
•	0	SCIF0_SCK	SCK	Input/output	Serial clock pin
					Clock input/output
		SCIF0_RxD	RxD* <sup>2</sup>	Input	Receive data pin
					Receive data input
		SCIF0_TxD	TxD* <sup>2</sup>	Output	Transmit data pin
					Transmit data output
		SCIF0_CTS	CTS	Input	Modem control pin
					Transmission possible
v.D	ataSheet4U	SCIF0_RTS	RTS	Output	Modem control pin
					Transmit request
٠	1	SCIF1_SCK	SCK	Input/output	Serial clock pin
					Clock input/output
		SCIF1_RxD	RxD* <sup>2</sup>	Input	Receive data pin
					Receive data input
		SCIF1_TxD	TxD* <sup>2</sup>	Output	Transmit data pin
					Transmit data output
		SCIF1_CTS	CTS	Input	Modem control pin
					Transmission possible
		SCIF1_RTS	RTS	Output	Modem control pin
					Transmit request

Notes: 1. The pins are collectively called SCK, RxD, TxD,  $\overline{\text{CTS}}$ , and  $\overline{\text{RTS}}$  without channel number in the following descriptions.

<sup>2.</sup> These pins are made to function as serial pins by setting SCIF operation with the TE and RE bits in SCSCR.

# 16.3 Register Descriptions

The SCIF has the following internal registers. For details on register addresses and register states in each processing state, refer to section 27, List of Registers.

#### Channel 0:

- Serial mode register\_0 (SCSMR\_0)
- Bit rate register 0 (SCBRR 0)
- Serial control register\_0 (SCSCR\_0)
- Transmit data stop register 0 (SCTDSR 0)
- FIFO error count register\_0 (SCFER\_0)
- Serial status register 0 (SCSSR 0)
- FIFO control register\_0 (SCFCR\_0)
- FIFO data count register\_0 (SCFDR\_0)
- Transmit FIFO data register\_0 (SCFTDR\_0)
- Receive FIFO data register\_0 (SCFRDR\_0)

#### Channel 1:

- Serial mode register\_1 (SCSMR\_1)
- Bit rate register\_1 (SCBRR\_1)
- Serial control register\_1 (SCSCR\_1)
- Transmit data stop register\_1 (SCTDSR\_1)
- FIFO error count register\_1 (SCFER\_1)
- Serial status register\_1 (SCSSR\_1)
- FIFO control register \_1(SCFCR\_1)
- FIFO data count register\_1 (SCFDR\_1)
- Transmit FIFO data register\_1 (SCFTDR\_1)
- Receive FIFO data register\_1 (SCFRDR\_1)

#### 16.3.1 Receive Shift Register (SCRSR)

SCRSR is the register used to receive serial data.

The SCIF sets serial data input from the RxD pin in SCRSR in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO data register, SCFRDR, automatically.

SCRSR cannot be directly read or written to by the CPU.

#### 16.3.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a 64-stage 8-bit FIFO register that stores received serial data (receive FIFO).

When the SCIF has received one byte of serial data, it transfers the received data from SCRSR to SCFRDR where it is stored, and completes the receive operation. SCRSR is then enabled for reception, and consecutive receive operations can be performed until the receive FIFO data register is full (64 data bytes).

SCFRDR is a read-only register, and cannot be written to by the CPU.

If a read is performed when there is no receive data in the receive FIFO data register, an undefined value will be returned. When the receive FIFO data register is full of receive data, subsequent serial data is lost.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFRD7 to SCFRD0	Undefined	R	Serial Receive Data FIFO

# 16.3.3 Transmit Shift Register (SCTSR)

SCTSR is the register used to transmit serial data.

To perform serial data transmission, the SCIF first transfers transmit data from SCFTDR to SCTSR, then sends the data sequentially to the TxD pin starting with the LSB (bit 0).

When transmission of one byte is completed, the next transmit data is transferred from SCFTDR to SCTSR, and transmission is started automatically.

SCTSR cannot be directly read or written to by the CPU.

## 16.3.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is an 8-bit 64-stage FIFO data register that stores data for serial transmission (transmit FIFO).

If SCTSR is empty when transmit data is written to SCFTDR, the SCIF transfers the transmit data written in SCFTDR to SCTSR and starts serial transmission.

SCFTDR is a write-only register, and cannot be read by the CPU.

The next data cannot be written when SCFTDR is filled with 64 bytes of transmit data. Data written in this case is ignored.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFTD7 to SCFTD0	Undefined	W	Serial Transmit Data FIFO

www.DataSheet4LL.com

# 16.3.5 Serial Mode Register (SCSMR)

SCSMR is a 16-bit readable/writable register used to set the SCIF's serial transfer format and select the baud rate generator clock source and the sampling rate.

Bit	Bit Name	Initial Value	R/W	Description
15 to	_	All 0	R	Reserved
11				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
10	SRC2	0	R/W	Sampling Control
9 8	SRC1 SRC0	0	R/W R/W	Select the sampling rate in asynchronous mode. This setting is valid only in asynchronous mode.
Ū	01100	Ü		000: Sampling rate 1/16
				001: Sampling rate 1/5
	et4U.com			010: Sampling rate 1/7
				011: Sampling rate 1/11
				100: Sampling rate 1/13
				101: Sampling rate 1/17
				110: Sampling rate 1/19
				111: Sampling rate 1/27
7	C/A	0	R/W	Communication Mode
				Selects whether the SCI operates in the asynchronous or clock synchronous mode.
				0: Asynchronous mode
				1: Clock synchronous mode
6	CHR	0	R/W	Character Length
				Selects seven or eight bits as the data length.
				This setting is only valid in asynchronous mode. In clock synchronous mode, the data length is always eight bits, regardless of the CHR setting.
				0: 8-bit data
				1: 7-bit data*
				Note: * When the 7-bit data is selected, the MSB bit (bit 7) in the transmit FIFO data register (SCFTDR) is not transmitted.

E	Bit	Bit Name	Initial Value	R/W	Description	
5	5	PE	0	R/W	Parity Enable	
					Selects whether or not parity bit addition is performed in transmission, and parity bit checking in reception.	n
					This setting is only valid in asynchronous mode. In synchronous mode, parity bit addition and checking is not performed, regardless of the PE setting.	
					0: Parity bit addition and checking disabled	
					1: Parity bit addition and checking enabled*	
					Note: *When the PE bit is set to 1, the parity (even or odd) specified by the O/E bit is added to transm data before transmission. In reception, the parity bit is checked for the parity (even or odd) specified by the O/E bit.	
4	1	O/E	0	R/W	Parity Mode	
		et4U.com			Selects either even or odd parity for use in parity addition and checking. The O/E bit setting is only valid when the PE bit is set to 1, enabling parity bit addition and checking. The O/E bit setting is invalid when parity addition and checking is disabled in asynchronous and clock synchronous mode.	
					0: Even parity*1	
					1: Odd parity* <sup>2</sup>	
					Notes: 1. When even parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even.	
					2. When odd parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total numbe of 1-bits in the receive character plus the parity bit is odd.	er.

Bit	Bit Name	Initial Value	R/W	Description
				·
3	STOP	0	R/W	Stop Bit Length
				Selects one or two bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit; if it is 0, it is treated as the start bit of the next transmit character.
				This setting is only valid in asynchronous mode. In clock synchronous mode, this setting is invalid since stop bits are not added.
				0: One stop bit*1
				1: Two stop bits*2
				Notes: 1. In transmission, a single 1-bit (stop bit) is added to the end of a transmit character before it is sent.
	eet4U.com			<ol><li>In transmission, two 1-bits (stop bits) are added to the end of a transmit character before it is sent.</li></ol>
2	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
1	CKS1	0	R/W	Clock Select
0	CKS0	0	R/W	Select the clock source for the on-chip baud rate generator.
				00: Pφ
				01: Pφ/4
				10: Pφ/16
				11: P

# 16.3.6 Serial Control Register (SCSCR)

SCSCR is a 16-bit readable/writable register that enables or disables the SCIF transfer operations and interrupt requests, and selects the serial clock source.

	Bit	Bit Name	Initial Value	R/W	Description
	15	TDRQE	0	R/W	Transmit Data Transmission Request Enable
					When transmitting data while TIE = 1 and transmit FIFO data empty has been generated, transmit FIFO data empty interrupt or DMA transfer request is selected.
					0: Interrupt request to CPU is performed
					1: Transmit data transmission request to the DMA is performed
	14	RDRQE	0	R/W	Receive Data Transmission Request Enable
w.Da	itaSheet	4U.com			When receiving data while RIE = 1 and received FIFO data full is generated, received FIFO data full interrupt or DMA transfer request is selected.
					0: Interrupt request to CPU is performed
					1: Transmit data transmission request to the DMA is performed
	13, 12	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
	11	TSIE	0	R/W	Transmit Data Stop Interrupt Enable
					Enables or disables generation of a transmit-data-stop interrupt when the TSE bit in SCFCR is enabled and the TSF flag in SCSSR is set to 1.
					0: Transmit-data-stop interrupt disabled*
					1: Transmit-data-stop interrupt enabled
					Note: * The interrupt request is cleared by clearing the TSF flag to 0 after reading 1 from it or clearing the TSIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ERIE	0	R/W	Receive Error Interrupt Enable
				Enables or disables generation of a receive-error (framing or parity error) interrupt when the ER flag in SCSSR is set to 1.
				0: Receive-error interrupt disabled*
				1: Receive-error interrupt enabled
				Note: *The interrupt request is cleared by clearing the ER flag to 0 after reading 1 from it or clearing the ERIE bit to 0.
9	BRIE	0	R/W	Break Interrupt Enable
				Enables or disables generation of a break-receive interrupt when the BRK flag in SCSSR is set to 1.
				0: Break-receive interrupt disabled*
				1: Break-receive interrupt enabled
				Note: * The interrupt request is cleared by clearing the BRK flag to 0 after reading 1 from it or clearing the BRIE bit to 0.
8	DRIE	0	R/W	Receive Data Ready Interrupt Enable
				Enables or disables generation of a receive-data-ready interrupt when the DR flag in SCSSR is set to 1.
				0: Receive-data-ready interrupt disabled*
				1: Receive-data-ready interrupt enabled
				Note: * The interrupt request is cleared by clearing the DR flag to 0 after reading 1 from it or clearing the DRIE bit to 0.
7	TIE	0	R/W	Transmit Interrupt Enable
				Enables or disables generation of a transmit-FIFO-data-empty interrupt request when the TDFE flag in SCSSR is set to 1.
				0: Transmit-FIFO-data-empty interrupt request disabled*
				1: Transmit-FIFO-data-empty interrupt request enabled
				Note: *The interrupt request is cleared by writing transmit data exceeding the transmit trigger set number to SCFTDR, reading 1 from the TDFE flag, then clearing it to 0, or clearing the TIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
6	RIE	0	R/W	Receive Interrupt Enable
				Enables or disables generation of a receive-FIFO-data-full interrupt request when the RDF flag in SCSSR is set to 1.
				0: Receive-FIFO-data-full interrupt request disabled*
				1: Receive-FIFO-data-full interrupt request enabled
				Note: *The interrupt requests is cleared by reading 1 from the RDF flag, then clearing the flag to 0, or clearing the RIE bit to 0.
5	TE	0	R/W	Transmit Enable
				Enables or disables the start of serial transmission by the SCIF.
				0: Transmission disabled
				1: Transmission enabled*
itaShe	et4U.com			Note: *The serial mode register (SCSMR) and FIFO control register (SCFCR) settings must be made, the transmit format decided, and the transmit FIFO reset, before the TE bit is set to 1. If settings of above registers are changed with the TE bit enabled, the operation cannot be guaranteed.
4	RE	0	R/W	Receive Enable
				Enables or disables the start of serial reception by the SCIF.
				0: Reception disabled* <sup>1</sup>
				1: Reception enabled* <sup>2</sup>
				Notes: 1. Clearing the RE bit to 0 does not affect the DR, ER, BRK, RDF, FER, PER, and ORER flags, which retain their state.
				<ol> <li>The serial mode register (SCSMR) and FIFO control register (SCFCR) settings must be made, the receive format decided, and the receive FIFO reset, before the RE bit is set to 1. If settings of above registers are changed with the RE bit enabled, the operation cannot be guaranteed.</li> </ol>
3, 2	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

		Initial		
Bit	Bit Name	Value	R/W	Description
1	CKE1	0	R/W	Clock Enable
0	CKE0	0	R/W	Select the SCIF clock source. The CKE1 and CKE0 bits must be set before determining the SCIF operating mode with SCSMR.
				00: Internal clock/SCK pin functions as input pin (input signal ignored)
				01: Internal clock/SCK pin functions as serial clock output*1
				10: External clock/SCK pin functions as clock input*2
				11: External clock/SCK pin functions as clock input*2
				When data is sampled by the on-chip baud rate generator, set bits CKE1 and CKE0 to B'00 (internal clock/SCK pin functions as input pin (input signal ignored)).
				When using the SCK pin as a port, set bits CKE1 and CKE0 to B'00.
	neet4U.com			Notes: 1. In synchronous mode, a clock with a frequency equal to the bit rate is output.
				<ol> <li>In asynchronous mode, a clock with a sampling rate should be input. For example, when the sampling rate is 1/16, a clock with a frequency of 8 times the bit rate should be input. When an external clock is not input, set bits CKE1 and</li> </ol>

CKE0 to B'00 or B'01.

# 16.3.7 FIFO Error Count Register (SCFER)

SCFER is a 16-bit read-only register that indicates the number of receive errors (framing or parity error).

Bit	Bit Name	Initial Value	R/W	Description
15, 14	_	All 0	R	Reserved
				These bits are always read as 0.
13	PER5	0	R	Parity Error Count
12	PER4	0	R	Indicates the number of data, in which parity errors are
11	PER3	0	R	generated, in receive data stored in the receive FIFO data register (SCFRDR) in asynchronous mode.
10	PER2	0	R	After setting the ER bit in SCSSR, the value of bits 13 to 8
9	PER1	0	R	indicates the number of parity error generated data.
8	PER0	0	R	When all 64 bytes of receive data in SCFRDR have parity
DataSheet	4U.com			errors, the PER5 to PER0 bits indicate 0.
7, 6	_	All 0	R	Reserved
				These bits are always read as 0.
5	FER5	0	R	Framing Error Count
4	FER4	0	R	Indicates the number of data, in which framing errors are
3	FER3	0	R	generated, in receive data stored in the receive FIFO data register (SCFRDR) in asynchronous mode.
2	FER2	0	R	After setting the ER bit in SCSSR, the value of bits 5 to 0
1	FER1	0	R	indicates the number of framing error generated data.
0	FER0	0	R	When all 64 bytes of receive data in SCFRDR have framing errors, the FER5 to FER0 bits indicate 0.

# 16.3.8 Serial Status Register (SCSSR)

SCSSR is a 16-bit readable/writable register that indicates the SCIF status.

However, 1 cannot be written to the ORER, TSF, ER, TDFE, BRK, RDF, and DR flags. Also note that in order to clear these flags to 0, they must be read as 1 beforehand. The TEND, FER, and PER flags are read-only flags and cannot be modified.

		Initial		
Bit	Bit Name	Value	R/W	Description
15 to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
9	ORER	0	R/(W)*	Overrun Error Flag
				Indicates that an overrun error occurred during reception.
				This bit is only valid in asynchronous mode.
				0: Reception in progress, or reception has ended successfully*1
				[Clearing conditions]
				Power-on reset or manual reset
				• When 0 is written to ORER after reading ORER = 1
				1: An overrun error occurred during reception*2
				[Setting condition]
				When serial reception is completed while receive FIFO is full
				Notes: 1. The ORER flag is not affected and retains its previous state when the RE bit in SCSCR is cleared to 0.
				<ol> <li>The receive data prior to the overrun error is retained in SCFRDR, and the data received subsequently is lost. Serial reception cannot be continued while the ORER flag is set to 1.</li> </ol>

			Initial			
	Bit	Bit Name	Value	R/W	Description	
	8	TSF	0	R/(W)*	Transmit Data Stop Flag	
					Indicates that the number of transmit data matches the value of SCTDSR.	
					0: Number of transmit data does not match the value of SCTDSR	
					[Clearing conditions]	
					Power-on reset or manual reset	
					• When 0 is written to TSF after reading TSF = 1	
					1: Number of transmit data matches the value of SCTDSR	
	7	ER	0	R/(W)*	Receive Error	
					Indicates that a framing error or parity error occurred during reception in asynchronous mode.*1	
					0: No framing error or parity error occurred during reception	
					[Clearing conditions]	
				Power-on reset or manual reset		
					• When 0 is written to ER after reading ER = 1	
					1: A framing error or parity error occurred during reception	
					[Setting conditions]	
					When the SCIF checks whether the stop bit at the end of	
					the receive data is 1 when reception ends, and the stop bit is $0^{\ast^2}$	
					When, in reception, the number of 1-bits in the receive	
					data plus the parity bit does not match the parity setting (even or odd) specified by the O/E bit in SCSMR	
					Notes: 1. The ER flag is not affected and retains its previous state when the RE bit in SCSCR is cleared to 0.  When a receive error occurs, the receive data is still transferred to SCFRDR, and reception continues.  The FER and PER bits in SCSSR can be used to determine whether there is a receive error in the	
					data read from SCFRDR.	
					<ol><li>When the stop length is two bits, only the first stop bit is checked for a value of 1; the second stop bit is not checked.</li></ol>	

		Initial		
Bit	Bit Name	Value	R/W	Description
6	TEND	1	R	Transmit End
				Indicates that there is no valid data in SCFTDR when the last bit of the transmit character is sent, and transmission has been ended.
				0: Transmission is in progress
				[Clearing condition]
				When data is written to SCFTDR
				1: Transmission has been ended
				[Setting condition]
				When there is no transmit data in SCFTDR on transmission of a 1-byte serial transmit character
5	TDFE	1	R/(W)*	Transmit FIFO Data Empty
.DataSheet4U.com				Indicates that data has been transferred from SCFTDR to SCTSR, the number of data bytes in SCFTDR has fallen to or below the transmit trigger data number set by bits TTRG1 and TTRG0 in the FIFO control register (SCFCR), and new transmit data can be written to SCFTDR.
				A number of transmit data bytes exceeding the transmit trigger set number have been written to SCFTDR
				[Clearing condition]
				When transmit data exceeding the transmit trigger set number is written to SCFTDR, and 0 is written to TDFE after reading TDFE = 1
				The number of transmit data bytes in SCFTDR does not exceed the transmit trigger set number
				[Setting conditions]
				Power-on reset or manual reset
				When the number of SCFTDR transmit data bytes falls to
				or below the transmit trigger set number as the result of a transmit operation*1
				Note: 1. As SCFTDR is a 64-byte FIFO register, the maximum number of bytes that can be written when TDFE = 1 is 64 – (transmit trigger set number). Data written in excess of this will be ignored. The number of data bytes in SCFTDR is indicated by SCFDR.

		Initial		
Bit	Bit Name	Value	R/W	Description
4	BRK	0	R/(W)*	Break Detect
				Indicates that a receive data break signal has been detected in asynchronous mode.
				0: A break signal has not been received
				[Clearing conditions]
				Power-on reset or manual reset
				<ul> <li>When 0 is written to BRK after reading BRK = 1</li> </ul>
				1: A break signal has been received*1
				[Setting condition]
				When data with a framing error is received, followed by the space 0 level (low level) for at least one frame length
				Note: 1. When a break is detected, the receive data (H'00) following detection is not transferred to SCFRDR. When the break ends and the receive signal returns to mark 1, receive data transfer is resumed.
3	FER	0	R	Framing Error
				Indicates a framing error in the data read from SCFRDR in asynchronous mode.
				0: There is no framing error in the receive data read from SCFRDR
				[Clearing conditions]
				Power-on reset or manual reset
				When there is no framing error in SCFRDR read data
				1: There is a framing error in the receive data read from SCFRDR
				[Setting condition]
				When there is a framing error in SCFRDR read data

Bit	Bit Name	Initial Value	R/W	Description
2	PER	0	R	Parity Error
				Indicates a parity error in the data read from SCFRDR in asynchronous mode.
				0: There is no parity error in the receive data read from SCFRDR
				[Clearing conditions]
				Power-on reset or manual reset
				When there is no parity error in SCFRDR read data
				1: There is a parity error in the receive data read from SCFRDR
				[Setting condition]
				When there is a parity error in SCFRDR read data
1	RDF	0	R/(W)*	Receive FIFO Data Full
	eet4U.com			Indicates that the received data has been transferred from SCRSR to SCFRDR, and the number of receive data bytes in SCFRDR is equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in the FIFO control register (SCFCR).
				0: The number of receive data bytes in SCFRDR is less than the receive trigger set number
				[Clearing conditions]
				Power-on reset or manual reset
				<ul> <li>When SCFRDR is read until the number of receive data bytes in SCFRDR falls below the receive trigger set number, and 0 is written to RDF after reading RDF = 1</li> </ul>
				1: The number of receive data bytes in SCFRDR is equal to or greater than the receive trigger set number
				[Setting condition]
				When SCFRDR contains at least the receive trigger set number of receive data bytes*1
				Note:1. SCFRDR is a 64-byte FIFO register. When RDF = 1, at least the receive trigger set number of data bytes can be read. If data is read when SCFRDR is empty, an undefined value will be returned. The number of receive data bytes in SCFRDR is indicated by the lower bits of SCFDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	Receive Data Ready
				Indicates that there are fewer than the receive trigger set number of data bytes in SCFRDR and no further data will arrive in asynchronous mode.
				Reception is in progress or has ended successfully and there is no receive data left in SCFRDR
				[Clearing conditions]
				Power-on reset or manual reset
				When all the receive data in SCFRDR has been
				read, and 0 is written to DR after reading $DR = 1$
				1: No further receive data has arrived
				[Setting condition]
vw.DataSheet	4U.com			When SCFRDR contains fewer than the receive trigger set number of receive data bytes and no further data will arrive.*
				Note: 1. The DR bit is set 15etu after the last data is received at a sampling rate of 1/16 regardless of the setting of the sampling control bits in SCSMR.
				etu: Elementary time unit (time for transfer of one bit)

Note: \* Only 0 can be written for clearing the flags.

## 16.3.9 Bit Rate Register (SCBRR)

SCBRR is an 8-bit readable/writable register that sets the serial transfer bit rate in accordance with the baud rate generator operating clock selected by bits CKS1 and CKS0 in SCSMR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCBRD7 to SCBRD0	H'FF	R/W	Bit Rate Setting

The SCBRR setting is found from the following equation.

## **Asynchronous Mode:**

1. When sampling rate is 1/16

$$N = \frac{P\phi}{32 \times 2^{2n-1} \times B} \times 10^{6} - 1$$

2. When sampling rate is 1/5

$$N = \frac{P\phi}{10 \times 2^{2n-1} \times B} \times 10^6 - 1$$

3. When sampling rate is 1/11

$$N = \frac{P\phi}{22 \times 2^{2n-1} \times B} \times 10^6 - 1$$

4. When sampling rate is 1/13

$$N = \frac{P\phi}{26 \times 2^{2n-1} \times B} \times 10^6 - 1$$

5. When sampling rate is 1/27

$$N = \frac{P\phi}{54 \times 2^{2n-1} \times B} \times 10^6 - 1$$

#### **Clock Synchronous Mode:**

$$N = \frac{P\phi}{4 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Where B: Bit rate (bits/s)

n:

N: SCBRR setting for baud rate generator

Asynchronous mode:  $0 \le N \le 255$ 

Clock synchronous mode:  $1 \le N \le 255$ 

Po: Peripheral module operating frequency (MHz)

Baud rate generator input clock (n = 0 to 3)

(See the table below for the relation between n and the clock.)

SCSMR Setting
---------------

n	Clock	CKS1	CKS0	
0	Рф	0	0	
DataSheet4U.com	Рф/4	0	1	
2	Рф/16	1	0	
3	Ρφ/64	1	1	

The bit rate error in asynchronous mode is found from the following equation:

1. When sampling rate is 1/16

Error (%) = 
$$\left(\frac{P\phi \times 10^6}{(1+N) \times B \times 32 \times 2^{2n-1}} - 1\right) \times 100$$

2. When sampling rate is 1/5

Error (%) = 
$$\left(\frac{P\phi \times 10^6}{(1+N) \times B \times 10 \times 2^{2n-1}} - 1\right) \times 100$$

3. When sampling rate is 1/11

Error (%) = 
$$\left(\frac{P\phi \times 10^6}{(1+N) \times B \times 22 \times 2^{2n-1}} - 1\right) \times 100$$

4. When sampling rate is 1/13

Error (%) = 
$$\left(\frac{P\phi \times 10^6}{(1+N) \times B \times 26 \times 2^{2n-1}} - 1\right) \times 100$$

# 5. When sampling rate is 1/27

Error (%) = 
$$\left(\frac{P\phi \times 10^6}{(1+N) \times B \times 54 \times 2^{2n-1}} - 1\right) \times 100$$

## 16.3.10 FIFO Control Register (SCFCR)

SCFCR is a 16-bit readable/writable register that resets the data count and sets the trigger data number for the transmit and receive FIFO registers, and also contains a loopback test enable bit.

	<b></b>	D. N	Initial		
	Bit	Bit Name	Value	R/W	Description
	15	TSE	0	R/W	Transmit Data Stop Enable
					Enables or disables the transmit data stop function.

				Invalidates the receive data in the receive FIFO data register and resets it to the empty state.
				0: Reset operation disabled*
				1: Reset operation enabled
				Note: * A reset operation is performed in the event of a power-on reset or manual reset.
0	LOOP	0	R/W	Loopback Test
				Internally connects the transmit output pin (TxD) and receive input pin (RxD), and RTS pin and CTS pin, enabling loopback testing.
				0: Loopback test disabled

1: Loopback test enabled

#### 16.3.11 FIFO Data Count Register (SCFDR)

SCFDR is a 16-bit read-only register that indicates the number of data bytes stored in the transmit FIFO data register (SCFTDR) and receive FIFO data register (SCFRDR).

Bits 14 to 8 show the number of transmit data bytes in SCFTDR, and bits 6 to 0 show the number of receive data bytes in SCFRDR.

	D:4	Dit Name	Initial	D/M	Description						
	Bit	Bit Name	Value	R/W	Description

	0	R0	0	R							

## 16.3.12 Transmit Data Stop Register (SCTDSR)

SCTDSR is an 8-bit readable/writable register that sets the number of transmit data bytes. SCTDSR is valid only when the TSE bit in the FIFO control register (SCFCR) is enabled. Transmit operation is stopped when the number of data bytes set in SCTDSR is transmitted. The setting value should be H'00 (one byte) to H'FF (256 bytes). This function is only enabled in asynchronous mode.

SCTDSR is initialized to H'FF.

# 16.4 Operation

#### **16.4.1** Overview

The SCIF can carry out serial communication in asynchronous mode, in which synchronization is achieved character by character, and in clock synchronous mode, in which synchronization is achieved with clock pulses.

64-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling fast, continuous communication to be performed.

### 16.4.2 Asynchronous Mode

The asynchronous mode is described below.

The transfer format is selected using the serial mode register (SCSMR), as shown in table 16.2. The SCIF clock source is determined by the CKE1 and CKE0 bits in the serial control register (SCSCR).

- Data length: Choice of seven or eight bits
- Choice of parity addition and addition of one or two stop bits (the combination of these parameters determines the transfer format and character length)
- Detection of framing errors, parity errors, overrun errors, receive-FIFO-data-full state, receive-data-ready state, and breaks, during reception
- Indication of the number of data bytes stored in the transmit and receive FIFO registers
- Choice of internal or external clock as the SCIF clock source
  - When internal clock is selected: the SCIF operates on the baud rate generator clock.
  - When external clock is selected: A clock must be input according to the sampling rate. For example, when the sampling rate is 1/16, a clock with a frequency of 8 times the bit rate must be input (the on-chip baud rate generator is not used.)

RENESAS

**Table 16.2** SCSMR Settings for Serial Transfer Format Selection

# 16.4.3 Serial Operation in Asynchronous Mode

**Data Transfer Format:** Table 16.3 shows the transfer formats that can be used in asynchronous mode. Any of eight transfer formats can be selected according to the SCSMR settings.

**Table 16.3 Serial Transfer Formats** 

SC	SMR S	ettings	Serial Transfer Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S			8	3-bit da				STOP			
		1	S	8-bit data									STOP	
	1	0	S			8	3-bit da	ta				Р	STOP	
.DataShe	eet4U.co	<b>1</b>	S			8	3-bit da	ta				Р	STOP	STOP
1	0	0	S			7	'-bit da	ta			STOP			
		1	S			7	'-bit da	ta			STOP	STOP		
	1	0	S			7	'-bit da	ta			Р	STOP		
	1 S 7-bit data										Р	STOP	STOP	

S: Start bit STOP: Stop bit P: Parity bit **Clock:** Either an internal clock generated by the on-chip baud rate generator or an external clock input at the SCK pin can be selected as the serial clock for the SCIF, according to the setting of the CKE1 and CKE0 bits in SCSCR.

When an external clock is input at the SCK pin, a clock must be input according to the sampling rate. For example, when the sampling rate is 1/16, a clock with a frequency of 8 times the bit rate must be input.

#### **Data Transfer Operations:**

#### 1. SCIF Initialization

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCSCR to 0, then initialize the SCIF as described below.

When the transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before

making the change using the following procedure. When the TE bit is cleared to 0, the transmit shift register (SCTSR) is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCSSR, SCFTDR, or SCFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCSSR has been set to 1. Clearing to 0 can also be performed during transmission, but the data being transmitted will go to the high-impedance state after the clearance. Before setting TE to 1 again to start transmission, the

When an external clock is used, the clock should not be stopped during operation, including initialization, since operation will be unreliable in this case.

TERST bit in SCECR should first be set to 1 to reset SCETDR.

Figure 16.2 shows a sample SCIF initialization flowchart.

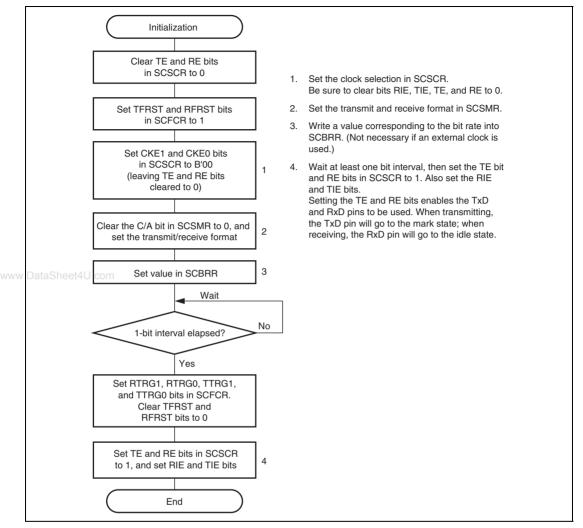

Figure 16.2 Sample SCIF Initialization Flowchart

#### 2. Serial Data Transmission

Figure 16.3 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling the SCIF for transmission.

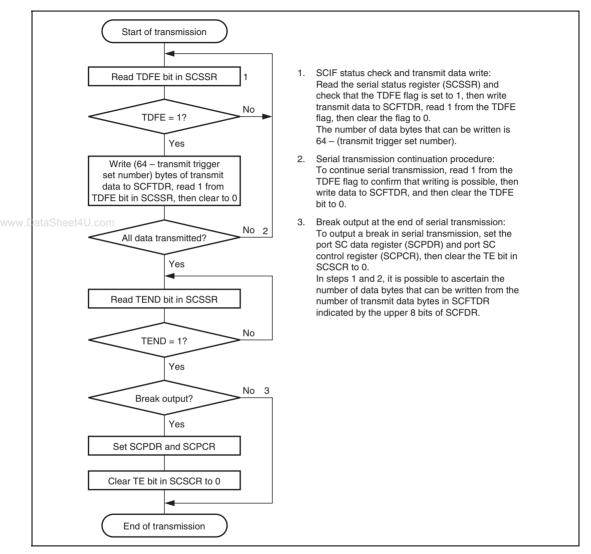

Figure 16.3 Sample Serial Transmission Flowchart

In serial transmission, the SCIF operates as described below.

A. When data is written into SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in the serial status register (SCSSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least 64 – (transmit trigger set number).

B. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive

transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls to or below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in SCSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated. When the transmit data stop function is used and the number of data bytes set in the transmit data stop register (SCTDSR) is matched, transmit operation is stopped, and the TSF flag in the serial status register (SCSSR) is set. If the TSIE bit in the serial control register (SCSCR) is set to 1, a transmit-data-stop-interrupt (TDI) request is generated. The vectors of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.

The serial transmit data is sent from the TxD pin in the following order.

ww.DataSheet<sup>4U</sup> Start bit: One 0-bit is output.

- b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
- c. Parity bit: One parity bit (even or odd parity) is output.A format in which a parity bit is not output can also be selected.
- d. Stop bit(s): One or two 1-bits (stop bits) are output.
- e. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
- C. The SCIF checks the SCFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCSSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output.

Figure 16.4 shows an example of the operation for transmission in asynchronous mode.

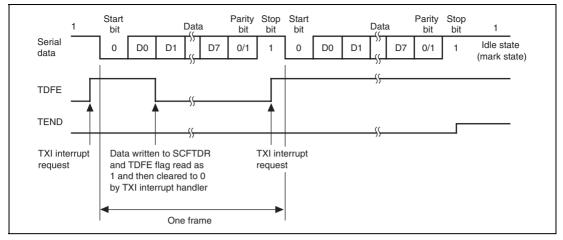

Figure 16.4 Example of Transmit Operation (Example with 8-Bit Data, Parity, One Stop Bit)

Transmit Data Stop Function

When a value in the SCTDSR register is matched with the number of transmit data bytes, this function stops the transmit operation. Interrupts can be generated and the DMAC can be activated by setting the TSIE bit (interrupt enable bit).

Figure 16.5 shows an example of operation for the transmit data stop function.

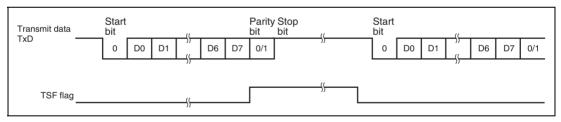

Figure 16.5 Example of Transmit Data Stop Function

Figure 16.6 shows a flowchart for the transmit data stop function.

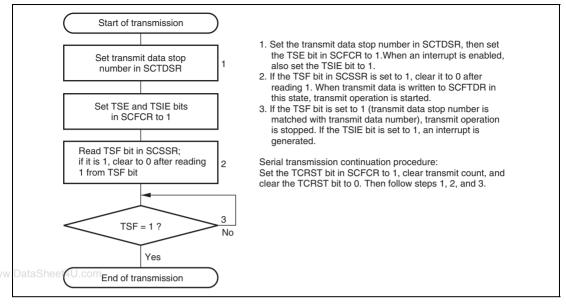

Figure 16.6 Transmit Data Stop Function Flowchart

### 3. Serial Data Reception

Figures 16.7 and 16.8 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling the SCIF for reception.

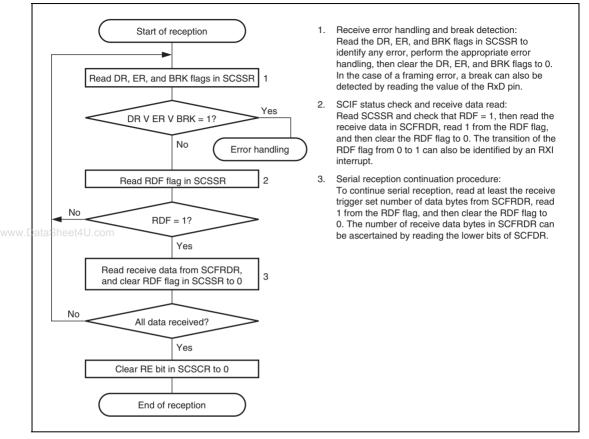

Figure 16.7 Sample Serial Reception Flowchart (1)

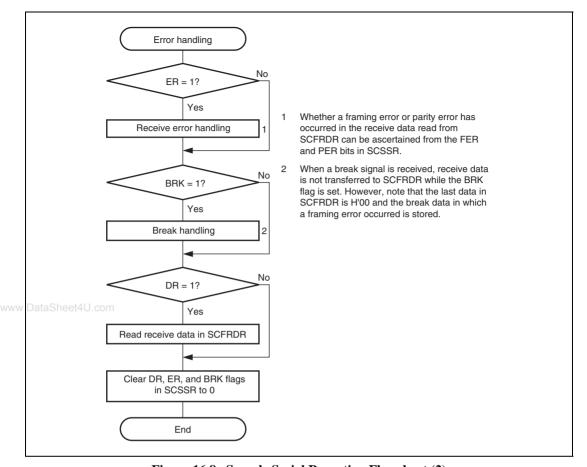

Figure 16.8 Sample Serial Reception Flowchart (2)

In serial reception, the SCIF operates as described below.

- A. The SCIF monitors the communication line, and if 0 of a start bit is detected, performs internal synchronization and starts reception.
- B. The received data is stored in SCRSR in LSB-to-MSB order.
- C. The parity bit and stop bit are received.

After receiving these bits, the SCIF carries out the following checks.

- a. Stop bit check: the SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
- b. The SCIF checks whether receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
- c. Break check: the SCIF checks that the BRK flag is 0, indicating that the break state is not set.

If all the above checks are passed, the receive data is stored in SCFRDR.

Note: Reception continues when a receive error (a framing error or parity error) occurs.

LaS De If the RIE bit in SCSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

If the ERIE bit in SCSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the BRIE bit in SCSCR is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

If the DRIE bit in SCSCR is set to 1 when the DR flag changes to 1, a receive-data-ready interrupt (DRI) request is generated.

The vectors of interrupts generated by each factor are the same.

Figure 16.9 shows an example of the operation for reception in asynchronous mode.

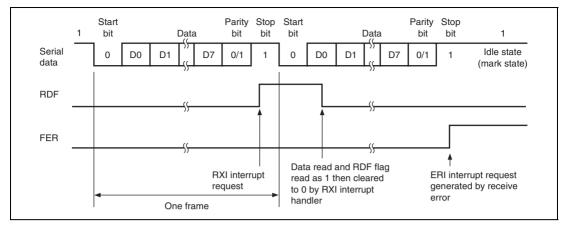

Figure 16.9 Example of SCIF Receive Operation (Example with 8-Bit Data, Parity, One Stop Bit)

# 4. Transmit/receive when using the Modem Function

When using a modem function, transmission can be stopped and started again according to the  $\overline{\text{CTS}}$  input value. When the  $\overline{\text{CTS}}$  is set to 1 during transmission, the data enters a mark state after transmitting one frame. When  $\overline{\text{CTS}}$  is set to 0, the next transmit data is output starting with a start bit.

Figure 16.10 shows an example of operation for the  $\overline{\text{CTS}}$  control.

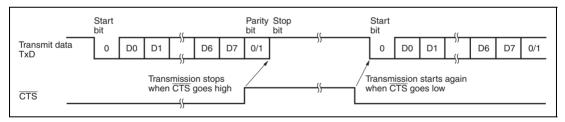

Figure 16.10 CTS Control Operation

When using a modem function and the receive FIFO (SCFRDR) is at least the number of the  $\overline{RTS}$  output trigger, the  $\overline{RTS}$  signal goes high.

Figure 16.11 shows an example of operation for the  $\overline{RTS}$  control.

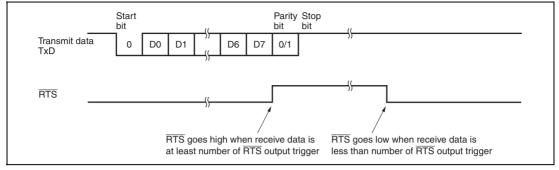

Figure 16.11 RTS Control Operation

### 16.4.4 Clock Synchronous Mode

ataSneet4U.com

The clock synchronous mode is described below.

64-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling fast, continuous communication to be performed.

The operating clock source is selected using the serial mode register (SCSMR). The SCIF clock source is determined by the CKE1 and CKE0 bits in the serial control register (SCSCR).

- Transmit/receive format: Fixed 8-bit data
- Indication of the number of data bytes stored in the transmit and receive FIFO registers
- Internal clock or external clock used as the SCIF clock source

When the internal clock is selected:

The SCIF operates on the baud rate generator clock and outputs a serial clock from SCK pin.

When the external clock is selected:

The SCIF operates on the external clock input through the SCK pin.

### 16.4.5 Serial Operation in Clock Synchronous Mode

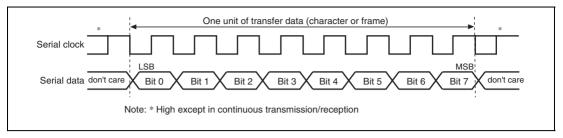

Figure 16.12 Data Format in Clock Synchronous Communication

In clock synchronous serial communication, data on the communication line is output from a falling edge of the serial clock to the next falling edge. Data is guaranteed valid at the rising edge of the serial clock.

In serial communication, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communication line remains in the state of the MSB.

In clock synchronous mode, the SCIF receives data in synchronization with the rising edge of the serial clock.

**Data Transfer Format:** A fixed 8-bit data format is used. No parity or multiprocessor bits are added.

**Clock:** An internal clock generated by the on-chip baud rate generator or an external clock input through the SCK pin can be selected as the serial clock for the SCIF, according to the setting of the CKE1 and CKE0 bits in SCSCR.

Eight serial clock pulses are output in the transfer of one character, and when no transmission/reception is performed, the clock is fixed high. However, when the operation mode is reception only, the synchronous clock output continues while the RE bit is set to 1. To fix the clock high every time one character is transferred, write to the transmit FIFO data register (SCFTDR) the same number of dummy data bytes as the data bytes to be received and set the TE and RE bits to 1 at the same time to transmit the dummy data. When the specified number of data bytes are transmitted, the clock is fixed high.

RENESAS

#### **Data Transfer Operations:**

#### 1 SCIF Initialization

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCSCR to 0, then initialize the SCIF as described below.

When the clock source, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, the transmit shift register (SCTSR) is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCSSR, SCFTDR, or SCFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCSSR has been set to 1. The TE bit should not be cleared to 0 during transmission; if attempted, the TxD pin will go to the high-impedance state. Before setting TE to 1 again to start transmission, the TFRST bit in SCFCR should first be set to 1 to reset SCFTDR.

Figure 16.13 shows sample SCIF initialization flowcharts.

## 16.5 SCIF Interrupt Sources and DMAC

The SCIF supports six interrupts in asynchronous mode—transmit-FIFO-data-empty (TXI), transmit-data-stop (TDI), receive-error (ERI), receive-FIFO-data-full (RXI), break-receive (BRI), and receive-data-ready (DRI). In clock synchronous mode, the SCIF supports two interrupts—transmit-FIFO-data-empty (TXI) and receive-FIFO-data-full (RXI). The vectors of each interrupt are the same.

Table 16.4 shows the interrupt sources. The interrupt sources can be enabled or disabled by means of the TIE, RIE, ERIE, BRIE, DRIE, and TSIE bits in SCSCR.

When the TDFE flag in SCSSR is set to 1, a TXI interrupt request is generated. When the TSF flag in SCSSR is set to 1, a TDI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of TXI and TDI interrupt requests. The DMAC requests of TXI and TDI are assigned to the same vector.

When the RDF flag in SCSSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of an RXI interrupt request.

When using the DMAC for transmission/reception, set and enable the DMAC before making SCIF settings. See section 10, Direct Memory Access Controller (DMAC), for details of the DMAC setting procedure.

When the ER flag in SCSSR is set to 1, an ERI interrupt request is generated.

When the BRK flag in SCSSR is set to 1, a BRI interrupt request is generated.

When the DR flag in SCSSR is set to 1, a DRI interrupt request is generated.

When the TSF flag in SCSSR is set to 1, a TDI interrupt request is generated.

The vectors of TXI, TDI, ERI, BRI, RXI and DRI are the same.

The DMAC activation and interrupts cannot be generated simultaneously by the same source. The following procedure should be used for the DMAC activation.

- 1. Set the interrupt enable bits (TIE, RIE and TDIE) corresponding to the generated source to 1.
- 2. Mask the corresponding interrupt requests by using the interrupt mask register of the interrupt controller.

### **Table 16.4 SCIF Interrupt Sources**

Description	DMAC Activation	
Interrupt initiated by receive error flag (ER) or break flag (BRK)	Not possible	
Interrupt initiated by receive FIFO data full flag (RDF) or receive data ready (DR)	Possible* <sup>1</sup>	
Interrupt initiated by transmit FIFO data empty flag (TDFE) or transmit data stop flag (TSF)	Possible* <sup>2</sup>	

- Notes: 1. The DMAC can be activated only by a receive-FIFO-data-full interrupt request.
  - 2. The DMAC can be activated by a transmit-FIFO-data-empty (TDFE) or transmit-datastop (TSF) interrupt request. When the DMAC is activated by the TSF interrupt, it is cleared by either of two cases listed below.
    - (1) The TSF flag is read by the CPU.
    - (2) The transmit FIFO is full.

See section 4, Exception Handling, for priorities and the relationship with non-SCIF interrupts.

www DataSheet4LLcom

www.DataSheet4U.com

## 16.6 Notes on Usage

Note the following when using the SCIF.

**SCFTDR Writing and the TDFE Flag:** The TDFE flag in the serial status register (SCSSR) is set when the number of transmit data bytes written in the transmit FIFO data register (SCFTDR) has fallen to or below the transmit trigger number set by bits TTRG1 and TTRG0 in the FIFO control register (SCFCR). After TDFE is set, transmit data up to the number of empty bytes in SCFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE clearing should therefore be carried out when SCFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCFTDR can be found from the 14 to 8 bits of the FIFO data count register (SCFDR).

**SCFRDR Reading and the RDF Flag:** The RDF flag in the serial status register (SCSSR) is set when the number of receive data bytes in the receive FIFO data register (SCFRDR) has become equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in the FIFO control register (SCFCR). After RDF is set, receive data equivalent to the trigger number can be read from SCFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCFRDR is still equal to or greater than the trigger number after a read, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all receive data has been read.

The number of receive data bytes in SCFRDR can be found from the 6 to 0 bits of the FIFO data count register (SCFDR).

**Break Detection and Processing:** Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state the input from the RxD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

Although the SCIF stops transferring receive data to SCFRDR after receiving a break, the receive operation continues.

**Receive Data Sampling Timing and Receive Margin:** As an example, when the sampling rate is 1/16, the SCIF operates on a base clock with a frequency of 8 times the transfer rate.

In reception, the SCIF synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse.

Figure 16.17 shows an example of asynchronous mode receive data sampling timing in asynchronous mode.

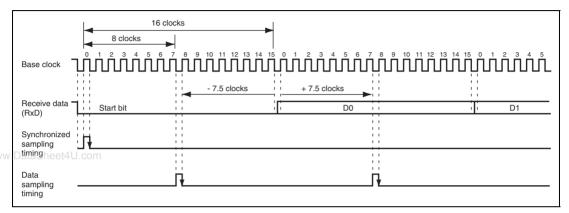

Figure 16.17 Receive Data Sampling Timing in Asynchronous Mode

The receive margin in asynchronous mode can therefore be expressed as shown in equation (1).

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{\left| D - 0.5 \right|}{N} (1 + F) \right| \times 100\% \dots (1)$$

M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty cycle (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation (2).

When D = 0.5 and F = 0:

$$\mathbf{M} = (0.5 - 1/(2 \times 16)) \times 100\% = 46.875\%$$
 (2)

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

**Initialize SCIF:** The communication format should be changed according to the following procedure after the TE and RE bits are cleared to 0. The transmit shift register (SCTSR) is initialized by clearing the TE bit to 0. The receive shift register (SCRSR) is initialized by clearing the RE bit to 0. The contents of the serial status register (SCSSR), transmit FIFO data register (SCFTDR), and receive FIFO data register (SCFRDR) is retained even when the TE and RE bits are cleared to 0. The TE bit should be cleared after all transmit data have been transmitted and the TEND bit in SCSSR has been set to 1. The TE bit can be cleared while the data transmission is in progress. However, the data go to high-impedance after the TE bit has been cleared to 0. To start transmission again by setting the TE bit to 1, the SCFTDR should be reset by setting the TFRST bit in SCFCR to 1.

The external clock should not be halted during the operation including an initialization since the operation becomes unstable.

**Transition to Power-Down Mode:** The transitions to software standby mode and module standby mode should not be made by setting the module standby bit of SCIF during serial transmission and reception. The transitions to software standby mode and module standby mode should be made after both TE and RE bits in the serial control register (SCSCR) have been cleared (transmission/reception disabled).

**Transmit/Receive Pin in Transmission/Reception Disabled State:** The TxD pin of the SCIF is in high-impedance state while the TE bit is cleared. The RxD pin is in input fixed state while the RE bit is cleared. Care is required on dealing a signal line that is connected to the TxD pin. When the connect destination pin is in input state, connect the pull-up register to a signal line.

www.DataSheet4U.con

# Section 17 Boot Function (BOOT)

This LSI has a boot function which is used to download, to the on-chip memory, the firmware needed for the initial programming of the external flash memory. This function enables updating programs and dumping contents after the flash memory has been mounted on the board. This function eliminates the need to provide external address and data buses for the programming of the flash memory when this LSI and the flash memory, in bare-chip form, are sealed in a single package. This makes it possible to dramatically reduce the number of pins.

#### 17.1 Features

- Automatic downloading of the initial programming program from SCIFO

  The operation of downloading, via the SCIFO, the initial programming program of the external flash memory to the on-chip memory (U memory), starts after a power-on reset. This transfer is synchronous and via the UART. This allows the downloading of any initial programming program according to the type of the external flash memory that is connected. If the specification defined in this section is conformed to, programs for purposes other than the initial programming of the external flash memory may be downloaded. The size of the program to be downloaded must be no more than 8,192 bytes and is otherwise freely determined.
- Automatic bit-rate adjustment
   Automatic adjustment of the bit-rate at which the program is downloaded via the SCIF0 is possible.
- High-speed execution of the downloaded program in on-chip memory
   Since the program downloaded from the SCIF0 is expanded in the on-chip RAM, it is executable at high speed.
- Execution of the downloaded program starts automatically on completion of downloading After the specific program has been downloaded, processing automatically branches to the start address (H'A55F0000) in the downloaded program. Execution thus automatically starts.

Note: Since the boot function is configured as a single circuit module, it is one of the target modules for power control by the module-standby function. The boot function is only necessary for boot processing. If, therefore, power consumption needs to be reduced in normal operation or in the sleep state, we recommend that the supply of the clock signal to the boot-function module be stopped by setting the MSTP43 bit in STBCR4 to 1. For details on the module-standby function, refer to section 13, Power-Down Modes.

Figure 17.1 shows the block diagram of the boot function (BOOT). The I/O pins for the bus state controller (BSC) (A23 to A0, D15 to D0,  $\overline{WE1}$  to  $\overline{WE0}$ ,  $\overline{CS0}$ , and  $\overline{RD}$ ) are connected to the external flash memory and the I/O pins for the SCIF0 (SCIF0\_RxD and SCIF0\_TxD) are connected to the external host.

www.DataSheet4U.com

# 17.2 Input/Output Pin

Table 17.1 shows the pin only for the boot function. For details on the pins that are connected to the external flash memory, refer to section 9, Bus State Controller (BSC); for details on the pins that are related to the SCIF0, refer to section 16, Serial Communication Interface with FIFO (SCIF); and, for details on the power-on reset pin (RESETP), refer to section 4, Exception Handling.

Table 17.1 Input/Output Pin

Pin Name	I/O	Function	
BOOT_E Input		Boot Enable Input	
		The state of this pin can only be switched during a reset.	

# 17.3 Register Description

The BOOT has no registers which are accessible by the CPU.

# 17.4 Operation

### 17.4.1 Address Space in Boot Mode

When the BOOT\_E pin is asserted to its low level by a power-on reset (RESETP = low), this LSI enters boot mode at the end of a reset. At this point, processing by this LSI would not normally branch to the reset vector. In boot mode, processing branches to the on-chip boot program instead, to initiate the boot function.

Because of the initial state by a reset, the CPU enters privileged mode. For details on privileged mode, refer to section 2.1, Processing States and Processing Modes. In boot mode, which differs from the normal privileged mode, area 0 in the external memory space is divided into the two areas shown in figure 17.2. The area from H'000000000 to H'01FFFFFF is exclusively used for the boot function. Access to locations in this area by the user is thus prohibited. The boot program is placed here. The area from H'020000000 to H'03FFFFFF is an area 0 which is the same as the area 0 of the normal privileged mode.

External address space H'00000000 H'00000000 Area 0 Space for mounting (max. 16Mbvtes) Area 1 H'04000000 (on-chip register and Area for on-chip memory) \<sub>H'01000000</sub> boot program H'08000000 Area 2 (Reserved) Shadow space H'0C000000 Area 3 H'02000000 H'10000000 Area 4 Space for mounting Shadow space (max. 16Mbytes) H'14000000 Area 5 (Reserved) H'03000000 H'18000000 Area 6 (Reserved) ١ Shadow space ١ Shadow space H'1C000000 Area 7 (Reserved) H'1FFFFFF H'03FFFFF Normal mode Boot mode

Figure 17.2 External Memory Space in Boot Mode

In the initial programming of the external flash memory, the reset vector always selects a branch to the address H'A0000000 (a virtual address as seen from the CPU) after the power-on reset signal has been cancelled and area 0 in the external address space is accessed. The programming program must thus be executed from a start address in area 0. In boot mode, however, addresses H'000000000 to H'01FFFFFF are exclusively used for the boot function, so programming is executed from the start address H'02000000. The maximum mounted area for this LSI is 16 Mbytes. Since the address range from H'02000000 to H'02FFFFF is the shadow space for the range from H'00000000 to H'00FFFFFF, if programming starts at address H'02000000, access can be performed from address H'000000000 after boot mode has been cancelled.

Note: The state of the input on the BOOT\_E pin input must not be changed except during a reset. If this state is changed, correct operation is not guaranteed.

### 17.4.2 Procedure for Execution of Boot Processing

The initial programming program of the external flash memory must be placed in the external host before the boot function is used. The initial programming program must be prepared in accordance with the programming algorithm for the external flash memory that is to be used.

The boot program starts preparing for the transfer of data to and from the external host over channel 0 of the SCIF. After the necessary initial settings for the SCIF0 have been made, the bit rate for use in transmission/reception is automatically adjusted to suit the external host. Figure 17.3 shows the procedure according to which boot processing is executed.

Automatic Adjustment Operation for SCIF0 Bit Transfer Rate: This LSI automatically adjusts the bit transfer rate for transmission/reception to a value in the range between 9.6 kbps and 38.4 kbps. When this LSI is activated in boot mode, it measures the period of the low levels in the synchronous data (H'00) which is continuously transmitted from the external host. Channel 0 in the timer unit (TMU) is used for this low-period measurement. Here, the external host must set the format for transfer between this LSI and the SCIF0 as 8-bit data, one stop bit, and no parity bit. After the boot program has calculated the bit rate at which bits are being transferred from the external host by using the measurement of the low period and the optimum setting has been made, a single byte with the value H'00 is transmitted to the external host as notification of the end of the bit-rate adjustment. After the external host has successfully received this notification of the end of bit-rate adjustment, a single byte with the value H'55 must be returned to this LSI. After this LSI has received this byte, it transmits a single byte with the value H'AA.

Note: If reception is not successful, execution enters an endless loop and the program will not react. In such a case, reinitiate boot mode after a reset, and repeat the above operations.

**Transferring of Initial Programming Program**: The boot program starts downloading the initial programming program after the automatic adjustment of the bit transfer rate has been completed. The maximum size of the initial programming program that is downloaded over the SCIFO channel is 8,192 bytes (H'2000)\*<sup>1</sup>. The downloaded initial programming program is stored in the address range from H'055F0000 to H'055F1FFF (physical addresses) in the on-chip memory (U memory). After the downloading has been completed, the boot program automatically branches to address H'055F0000\*<sup>2</sup>. Therefore the start address of the program that is downloaded must be H'055F0000.

Although the boot program uses the address range from H'055FFFFC to H'055FFFFF (physical addresses) as a working area, the downloaded initial programming program is able to use this area after downloading has been completed.

- Notes: 1. The size setting for the initial programming program must not be H'0000 or greater than H'2001, as normal operation is not possible in such a case. If such a program is used, correct operation is not guaranteed.
- 2. The initial setting routine of user program that is programmed by the initial www.DataSheet4U programming program in boot mode should be stored from H'02000000 in area 0. The initial setting is enabled since the branch to the first address of area 0 (H'00000000) is made immediately after a power-on reset in normal mode.

A maximum of 16 Mbytes may be mounted in area 0, i.e., the address range from H'02000000 to H'02FFFFFF is available (H'00000000 to H'00FFFFFF in normal mode) as shown in figure 17.2.

In this LSI, external memory may be mounted in areas 3 and 4 as well as in area 0. The maximum size for each area is 16 Mbytes. Areas 3 and 4 may be used as expansion spaces for the external flash memory, when this is necessary, by preparing a corresponding initial programming program.

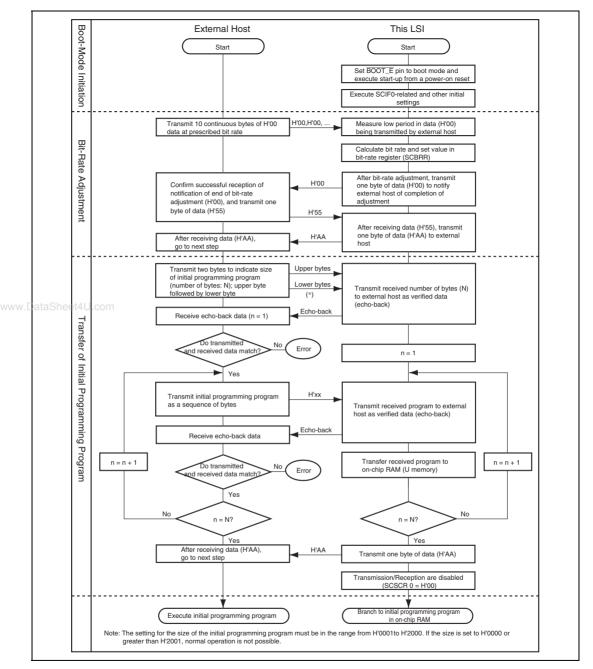

Figure 17.3 Procedure for Execution of Boot Processing

## 17.5 Usage Note

### 17.5.1 Endian when Using Boot Function

The boot function is operated by the firmware that is stored in the boot ROM and functions on big endian. Therefore, when the  $\overline{BOOT}_{-}E$  pin is asserted to its low level by a power-on reset ( $\overline{RESETP}$  = low), the MD5 pin should be driven low (big endian mode). After the specific program has been downloaded, the boot function is branched to the start address in the initial programming program for the external flash memory downloaded in the on-chip memory (U-memory). The initial programming program needs to be specified to operate on big endian. To execute normal operation on little endian, pay attention to the code alignment when the flash memory is initially programmed.

### 17.5.2 Clock Frequency and Data Transfer Rate when Using Boot Function

The transfer rate of SCIF which communicates with an external host when the boot function is used has the limitation shown in table 17.2. Note that a proper value should be set for the transfer rate in the program for the external host, such as "exflash".

Table 17.2 Clock frequency and data transfer rate of SCIF when boot function is used

CPG setting	Input clock frequency	SCIF transfer rate
Mode 5	10MHz or more	9600bps
Clock ratio	13MHz or more	19200bps
$I\phi:B\phi:P\phi=2:2:1$	16MHz or more	38400bps
Mode 7	20MHz or more	9600bps
Clock ratio	26MHz or more	19200bps
$I\phi:B\phi:P\phi=1:1:1/2$	32MHz or more	38400bps

# Section 18 USB Pin Multiplex Controller (USBPM)

#### 18.1 Feature

The USB pin multiplex controller controls the data path to USB transceiver from USB host controller or USB function controller. This USB pin multiplex controller also incorporates a clock select control function that selects the clock signal to be provided to the USB host controller and USB function controller as either an internally generated clock or externally input clock.

Both the USB host controller and the USB function controller are connected to the USB transceiver via multiplexer that is controlled by the EXCPG control register (EXCPGCR). The USB transceiver can be connected to USB host controller or USB function controller.

This LSI generates a 48-MHz clock, which is specified by the USB1.1 specifications, by the onchip multiplier circuit using a13-MHz clock input from the RDI\_REFCLK\_IN pin and provides
the clock to the USB host controller and USB function controller. A 48-MHz clock can also be
www.Datexternally-provided to the USB host controller and USB function controller. The on-chip
multiplier circuit allows the user to receive a stable clock from the RF-IC to be connected to this
LSI directly without connecting 48-MHz TCXO externally. Note, however, that a specific length
of jitter may occur when the on-chip multiplier circuit is used. Before using a clock provided from
the on-chip multiplier circuit, check the connectivity to other USB devices.

Figure 18.1 shows the USB pin multiplexer indicating the connection among the on-chip USB host controller, USB function controller, on-chip port 1 analog USB transceiver, and clock control circuit.

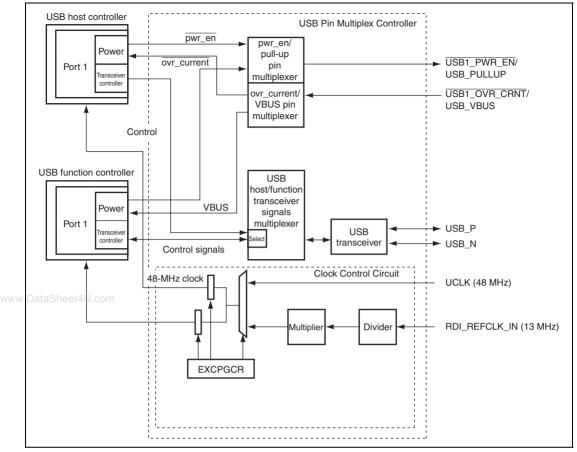

Figure 18.1 Block Diagram of this USB

# 18.2 Input/Output Pins

USB pin multiplexer controller has pins that are shown in tables 18.1, 18.2, and 18.3

**Table 18.1 Pin Configuration (Analog Transceiver Signal)** 

Pin Name	I/O	Description
USB_P	Input/Output	P pin
		D+ port transceiver pin
USB_N	Input/Output	D pin
		D- port transceiver pin

Note: The pins shown in table 18.1 can be used as port 1 USB host controller pins, or port 1 USB function controller pins. Ensure these pins are open when not used.

**Table 18.2** Pin Configuration (Power Control signal)

Dat <b>a</b> 9	n Name om	I/O	Description
	USB_PWR_EN/ USB_PULLUP	Output	Power enable pin/ USB pull-up control pin
US			Enables power supply (USBH)/controls USB pull-up (USBF)*
	USB_OVR_CRNT/	NT/ Input	Over-current pin/VBUS pin
US	SB_VBUS		Detects over-current (USBH)/monitors USB cable connection (USBF)*

Note: The pins shown in table 18.2 can be used for power control for USB. Pins indicated by \* have multiplexed functions for the USB host controller (USBH) and the USB function controller (USBF).

**Table 18.3** Pin Configuration (Clock Control signal)

Pin Name	I/O	Description	
RDI_REFCLK_IN	Input	Bluetooth interface clock pin	
		Pin for the Bluetooth interface clock (13MHz) input (generates a 48-MHz clock by the on-chip multiplier)	
UCLK	Input	External clock pin	
		Pin for the 48-MHz clock input from an external device	

Note: A 48-MHz clock is provided to the USBH or USBF by using RDI\_REFCLK\_IN or UCLK.

# 18.3 Register Description

Register configuration of the USB pin multiplexer controller is described below. See section 27, List of Registers, for the addresses of this register and the state of it in each processing status.

• EXCPG control register (EXCPGCR)

### **18.3.1 EXCPG Control Register (EXCPGCR)**

EXCPGCR controls providing a 48-MHz clock to the USB host controller and USB function controller and performs module reset.

	Bit	Bit Name	Initial Value	R/W	Descriptions
	7 to 5	_	All 0	R	Reserved
		t4U.com			These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
	4	USBVALID	0	R	USB Status
					The USB module status bit that Indicates whether the USB module (both the USB host and USB function controllers) can be used or not. This bit is a read-only bit. A write access to this bit is ignored. Immediately after power-on reset of the USB module, immediately returning from the software standby, or immediately after reset by USBRESET, the USB module cannot be used for a short time. Before using the USB module, check this bit status.
					Note: Even if the USBHSTP and USBFSTP bits are set, the on-chip multiplier circuit does not stop and this bit remains set to 1.
					0: USB module cannot be used.
					1: USB module can be used.

		Initial		
Bit	Bit Name	Value	R/W	Descriptions
3	USBRESET	1	R/W	USB Reset
				The USB module reset bit to be used to reset the USB module (both the USB host and USB function controllers). If this bit is cleared to 0, the USBVALID bit is cleared to 0 after approximately 1 $\mu s$ . After checking that the USBVALID bit is cleared to 0, set the USBRESET bit to 1. After this USBRESET bit is set to 1, the USB module starts the reset sequence. After the reset sequence, the USBVALID bit is set to 1 again. To ensure USB module initialization, follow the above sequence.
				To provide a clock again to the USB module after the clock has been stopped using the USBHSTP and USBFSTP bits, USB module operation may be unstable. Therefore, use the USB module after resetting by this bit.
				0: USB module is reset.
taShee	t4U.com			1: USB module is in normal operation.
2	USBHSTP	0	R/W	Module Stop USBH
				The USB host controller stop bit to be used to provide or stop the USB host controller operating clock. Clearing this bit to 0 provides the clock to the USB host controller. Setting this bit to 1 stops the clock. If both the USBHSTP and USBFSTP bits are set to 1 or cleared to 0, the USB transceiver operation stops. The USB_P and the USB_N outputs pins enter the high-impedance state, and then USB_PWR_EN/USB_PULLUP pin is brought low. Before using the USB host or USB function controller, clear one of USBHSTP or USBFSTP to 0. Note that the USB host controller and USB function controller cannot be used simultaneously. If the USB module control register is accessed while both the USBHSTP and USBFSTP bits are cleared to 0, correct operation cannot be guaranteed.
				Note that the USB host controller register access is ignored while the clock provided to the USB host controller is stopped.
				0: USB host controller operation continues.
				1: Stop providing clock to the USB host controller.

			Initial		
	Bit	Bit Name	Value	R/W	Descriptions
•	1	USBFSTP	0	R/W	Module Stop USBF
					The USB function controller stop bit to be used to provide or stop the USB function controller operating clock. Clearing this bit to 0 provides the clock to the USB function controller. Setting this bit to 1 stops the clock. If both the USBHSTP and USBFSTP bits are set to 1 or cleared to 0, the USB transceiver operation stops. The USB_P and the USB_N outputs pins enter the high-impedance state, and then the USB_PWR_EN/USB_PULLUP pin is brought low. Before using the USB host or USB function controller, clear one of USBHSTP and USBFSTP to 0. Note that the USB host controller and USB function controller cannot be used simultaneously. If the USB module control register is accessed while both the USBHSTP and USBFSTP bits are cleared to 0, correct operation cannot be guaranteed.
w.D		eet4U.com			Note that the USB function controller register access is ignored while the clock provided to the USB function controller is stopped.
					0: USB function controller operation continues.
					1: Stop providing clock to the USB function controller.
	0	USBCLKSEL	. 0	R/W	USB Clock Select
					The USB clock source select bit used to select whether the USB clock is internally generated or the USB clock is externally input. After this bit is modified, both the USB host and the USB function controllers must be initialized by the USBRESET bit.
					0: The USB clock is generated internally.
					1: The USB clock is input by the UCLK pin.

# 18.4 Examples of External Circuit

#### 18.4.1 Example of the Connection between USB Function Controller and External Circuit

Figures 18.2 and 18.3 show example connections of USB function controller and external circuit. When the USB function controller is used, a signal must be provided to the cable connection monitor pin (USB\_VSBUS). The USB\_VBUS pin is multiplexed with the USB\_OVR\_CRNT pin, and writing 0 to USBFSTP and 1 to USBHSTP in EXCPGCR register selects the USB\_VBUS pin functions. According to the status of the USB\_VBUS pin, the USB function controller recognizes whether the cable is connected/disconnected. Also, pin D+ must be pulled up in order to notify the USB host/hub that the connection is established. The sample circuits in figures 18.2 and 18.3 use the USB\_PULLUP pin for pull-up control.

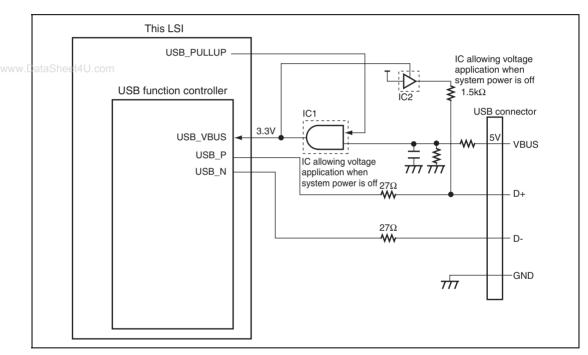

Figure 18.2 Example 1 of Connection between USB Function Controller and External Circuit

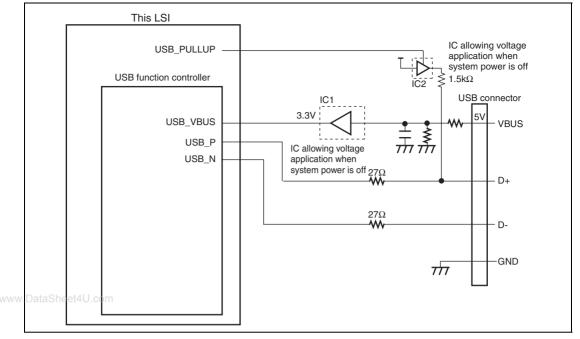

Figure 18.3 Example 2 of Connection between USB Function Controller and External Circuit

#### • D+ Pull-up Control

Control D+ pull-up via the USB\_PULLUP pin in the system in case that the connection-notification (D+ pull-up) of connection to the USB host controller or hub is to be inhibited (i.e., during high-priority processing or initialization processing).

The D+ pull-up control signal and USB\_VBUS pin input signal should be controlled via the USB\_PULLUP pin and the USB cable VBUS (AND circuit) as shown in the examples in figure 18.2.

D+ pull-up is inhibited when the USB\_PULLUP pin is low in an example of figure 18.2. (The initial setting of the USB\_PWR\_EN/USB\_PULLUP pin is low.)

Pull-up D+ after confirming that USB\_VBUS pin became high, when the pull-up control is performed directly by USB\_PULLUP pin as is shown in an example of figure 18.3.

Use an IC such that allows voltage application when system power is off (for example, HD74LV1G126A) for the pull-up control IC (IC2 in figures 18.2 and 18.3).

(The UDC core in this LSI holds the powered state when USB\_VBUS pin is low, regardless of the D+/D- state.)

• Detection of USB Cable Connection/Disconnection

As USB function controller in this LSI manages the state by hardware, USB\_VBUS signal is necessary to recognize connection or disconnection of the USB cable. The power supply signal (VBUS) in the USB cable is used for USB\_VBUS. However, if the cable is connected to the USB host or hub when the power of USB function controller (this LSI—installed system) is off, a voltage of 5 V will be applied from the USB host controller or hub.

Therefore, use an IC such that allows voltage application when system power is off (for example, HD74LV1G08A) for the IC1 in figures 18.2 to 18.3.

#### 18.4.2 Example of the Connection between USB Host Controller and External Circuit

Figure 18.4 shows example connections of the USB host controller and external circuit. When using the USB host controller, a separate LSI must be used for USB power bus control (equivalent to the USB power control LSI's in figure 18.4). Make sure the LSI has the power supply capacity to satisfy the USB standard, and select one that has an overcurrent protection function. Configure the system so that the input to the USB\_OVR\_CRNT pin is Low on detection of an overcurrent.

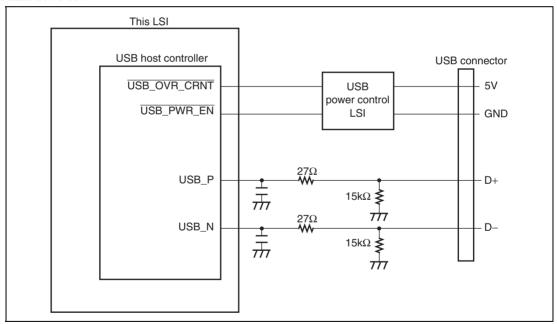

Figure 18.4 Example of Connection USB Host Controller and External Circuit

# 18.5 Usage Notes

**About the Examples of External Circuit:** These examples of connection with an external circuit in this chapter are for reference only, therefore proper operation is not guaranteed with these circuit examples. If system countermeasures are required for external surges and ESD noise, use a protective diode, etc.

**About the Clock Input to the USB:** When the USB clock is generated internally, the clock source is generated not by an input clock from the EXTAL pin specified as the CPU clock source but an input clock by the RDI\_REFCLK\_IN pin specified as clock used for data I/O with the RF-IC of the Bluetooth and the link controller. To use the USB function of this LSI without being connected to the RF-IC of the Bluetooth, the USB should be input the 13-MHz clock conforming to the USB standard by the RDI\_REFCLK\_IN pin. To use the USB function of this LSI without being connecting to the RF-IC of the Bluetooth actually, input of 48-MHz clock conforming to the USB standard by means of the UCLK pin is recommended.

**Problems with Using Non-specified Commercial USB Cable:** Some USB cables on the market do not meet the specification, and there are confirmed cases of non-specified USB cable to have problems with connectivity.

Use only specified USB cable with this product.

# Section 19 USB Host Controller (USBH)

The USB host controller module (hereafter referred to as the host controller) incorporated in this LSI supports the Open Host Controller (OpenHCI) Specification for the Universal Serial Bus (USB) as well as the universal serial bus specification ver.1.1.

The OpenHCI specification for the USB is a register-level description of the host controller. It is necessary to refer the OpenHCI specification to develop drivers for this host controller and hardware.

#### 19.1 **Features**

The host controller in this LSI has the following features:

- Conforms to the OpenHCI specification ver.1.0 register set
- Corresponding to the universal serial bus specification ver.1.1
- www.DaeS Supports root hub function
  - Supports low-speed (1.5 Mbps) and full-speed (12 Mbps) modes
  - Supports overcurrent detection
  - Supports 127-endpoint control in maximum

# 19.2 Input/Output Pins

Table 19.1 shows the pin configuration of the USB host controller.

For the detailed method for setting each pin, refer to section 18, USB Pin Multiplex Controller(USBPM).

**Table 19.1 Pin Configuration** 

Pin Name I/O		Function
UCLK	Input	External Clock Pin
		For direct input to 48MHz clock from an external device
RDI_REFCLK_IN	Input	External clock input
		The 13 MHz external clock is input. This signal is multiplied internally, and the clock of 48 MHz is generated.
USB_PWR_EN/	Output	Power Enable Pin/Pull-up Control Pin
USB_PULLUP		Enables power supply (USBH)/controls USB pull-up (USBF)
USB_OVR_CRNT/	Input	Overcurrent Pin/ VBUS Pin
USB_VBUS		Detects over-current (USBH)/monitors USB cable connection (USBF)
USB_P	Input/	P Pin
	Output	D+ port transceiver pin
USB_N	Input/	N Pin
	Output	D- port transceiver pin

Note: Either of RDI\_REFCLK\_IN or UCLK is used for 48MHz clock of the USB.

# 19.3 Register Descriptions

The USB host controller (USBH) has the following registers. For details on register addresses and register states during each processing, refer to section 27, List of Registers.

- HcRevision register (HREVR)
- HcControl register (HCTLR)
- HcCommandStatus register (HCSR)
- HcInterruptStatus register (HISR)
- HcInterruptEnable register (HIER)
- HcInterruptDisable register (HIDR)
- HcHCCA register (HHCCAR)
- HcPeriodCurrentED register (HPCEDR)
- HcControlHeadED register (HCHEDR)
- HcControlCurrentED register (HCCEDR)
- www.DataShrcBulkHeadED register (HBHEDR)
  - HcBulkCurrentED register (HBCEDR)
  - HcDoneHeadED register (HDHEDR)
  - HcFmInterval register (HFIR)
  - HcFmRemaining register (HFRR)
  - HcFmNumber register (HFNR)
  - HcPeriodicStart register (HPSR)
  - HcLSThreshold register (HLSTR)
  - HcRhDescriptorA register (HRDRA)
  - HcRhDescriptorB register (HRDRB)
  - HcRhStatus register (HRSR)
  - HcRhPortStatus1 register (HRPSR)

# 19.3.1 HcRevision Register (HREVR)

HREVR includes the BCD expression of the HCI specification version implemented for the host controller. The value H'10 corresponds to the version 1.0. All HCI implementation conforming to this specification have the value of H'10.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0.
7	REV7	0	R	Revision
6	REV6	0	R	Version Number (BCD Expression)
5	REV5	0	R	H'10: Version 1.0
4	REV4	1	R	
3 DataSheet/	REV3	0	R	
2	REV2	0	R	
1	REV1	0	R	
0	REV0	0	R	

# 19.3.2 HcControl Register (HCTLR)

HCTLR specifies the operation mode for the host controller.

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
8	IR	0	R/W	Interrupt Routine
				Determines the issue of interrupts generated by the event registered in the HcInterruptStatus register. The host controller driver clears this bit at the same time as the hardware reset, however, does not clear at the same time as the software reset. The host controller driver uses this bit as a tag to indicate the ownership of the host controller.
				0: All interrupts are issued to the interrupt mechanism of the normal host bus.
				1: Interrupts are issued to SMI.
7	HCFS1	0	R/W	Host Controller Function Status
6	HCFS0	0	R/W	The host controller driver detects whether the host controller has started to transmit SOF after having read the SF bit in the HcInterruptStatus register. This bit can be changed only in the USB Suspend state by the host controller. The host controller can move from the USB Suspend state to the USB Resume state after having detected the resume signal from the downstream port. In the host controller, USB Suspend is entered after the software reset so that USB Reset is entered after the hardware reset. The former resets the route hub.
				00: USB Reset 01: USB Resume 10: USB Operational 11: USB Suspend

Bit	Bit Name	Initial Value	R/W	Description
5	BLE	0	R/W	Bulk List Enable
				This bit is set to enable the processing of the bulk list in the next frame. The host controller checks this bit when the processing of the list has been determined. When disabling, the host controller driver can correct the list. When the HcBulkCurrentED register indicates ED* to be deleted, the host controller driver should hasten the pointer by updating the HcBulkCurrentED register before re-enabling the list processing.
				<ul><li>0: Bulk list processing is not carried out.</li><li>1: Bulk list processing is carried out.</li></ul>
4	CLE	0	R/W	Control List Enable
ataSheet4				This bit is set to enable the processing of the control list in the next frame. If cleared by the host controller driver, the processing of the control list is not carried out after next SOF. The host controller must check this bit whenever the list will be processed. When disabling, the host controller driver can correct the list. When the HcControlCurrentED register indicates ED to be deleted, the host controller driver should hasten the pointer by updating the HcControlCurrentED register before reenabling the list processing.
				<ul><li>0: Control list processing is not carried out.</li><li>1: Control list processing is carried out.</li></ul>
3	IE	0	R/W	Isochronous Enable
				This bit is used by the host controller driver to enable/disable the processing of isochronous ED. While processing the periodic list in the frame, the host controller will check the status of this bit when it finds an isochronous ED (F = 1). If set (enabled), the host controller continues to process ED. If cleared (disabled), the host controller stops the processing of the periodic list (currently includes only isochronous ED) and starts to process the bulk/control list. Setting this bit is guaranteed to be valid in the next frame (not in the current frame).
				Isochronous ED processing is not carried out.     Isochronous ED processing is carried out.

Bit	Bit Name	Initial Value	R/W	Description
2	PLE	0	R/W	Periodic List Enable
				This bit is set to enable the processing of the periodic list in the next frame. If cleared by the host controller driver, no periodic list processing is carried out after next SOF. The host controller must check this bit before the host controller starts to process the list.
				0: The periodic list processing is not carried out after next SOF.
				<ol> <li>The periodic list processing is carried out after next SOF.</li> </ol>
1	CBSR1	0	R/W	Control Bulk Service Ratio
0 taSheet4U	CBSR0	0	R/W	This bit specifies the service ratio of the control and bulk ED. The host controller must compare the ratio specified by the internal calculation whether it has processed control ED in determining whether another control ED is continued to be supplied or switched to bulk ED before any periodic list is processed. The internal calculation is retained when the frame boundary is exceeded. In case of reset, the host controller driver is responsible for restoring this value.
				00: 1:1 01: 2:1 10: 3:1 11: 4:1

Note: \* ED is Endpoint Descriptor.

#### 19.3.3 HcCommandStatus Register (HCSR)

. ... .

HCSR is used by the host controller not only for reflecting the current status of the host controller, but also for receiving a command issued by the host controller driver. A write is for setting the host controller driver. The host controller must guarantee that the bit to which 1 is written to is set and the bit to which 0 is written to is unchanged. The host controller driver can distribute multiple clear commands to the host controller by a previously issued command. The host controller driver can read all bits normally.

The SOC0 and SOC1 bits indicate the number of the frame that has detected the SchedulingOverrun error by the host controller. This occurs when the periodic list has not completed before EOF. When the SchedulingOverrun error is detected, the host controller increments the counter and sets the SO field in the HcInterruptStatus register.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 18		All 0	R	Reserved
DataOneet				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
17	SOC1	0	R/W	Scheduling Overrun Count
16	SOC0	0	R/W	These bits are incremented when each SchedulingOverrun error occurs. These bits are initially set to B'00 and returned to B'11. These bits are incremented when a SchedulingOverrun error is detected even though the SO bit in the HcInterruptStatus register is set. These bits are used by the host controller driver to monitor any continuous scheduling problem.
15 to 4	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
3	OCR	0	R/W	Ownership Change Request
				This bit is set by the OS host controller driver to request the change of the control of the host controller. When this bit is set, the host controller sets the OC bit in the HcInterruptStatus register. After a change, this bit is cleared and remains until the next request from the OS host controller driver.
				O: After a change, this bit is cleared and remains until the next request from the OS host controller driver.  1: Set the OC bit in the HcInterruptStatus register.

Bit	Bit Name	Initial Value	R/W	Description
2	BLF	0	R/W	Bulk List Filled
				This bit is used to indicate that there are some TDs in the list. This bit is set by the host controller driver to the list when TD* is added to ED.
				When the host controller starts to process the head of the list, it checks this bit. As long as this bit is 0, the host controller does not start to process the list. When this bit is 1, the host controller starts to process the list to set this bit to 0. When the host controller detects TD in the list, the host controller sets this bit to 1. When TD is never found in the list and the host controller driver does not set this bit, the host controller completes the processing of the list. This bit is still 0 when the bulk list processing is stopped.
				<ul><li>0: The list is not processed.</li><li>1: The list is processed.</li></ul>
1 ntaSheet4U	CLF	0	R/W	Control List Filled
				This bit is used to indicate that there are some TDs in the control list. This bit is set by the host controller driver when TD is added to ED in the control list.
				When the host controller starts to process the head of the control list, it checks this bit. As long as this bit is 0, the host controller does not start to process the control list. If this bit is 1, the host controller starts to process the control list and this bit is set to 0. When the host controller detects TD in the list, the host controller sets this bit to 1. When TD is never detected in the control list and the host controller driver does not set this bit, the host controller completes the processing of the control list. This bit is still 0 when the control list processing is stopped.
				O: The list is not processed.  1: The list is processed.

Bit	Bit Name	Initial Value	R/W	Description
0	HCR	0	R/W	Host Controller Request
				This bit is set by the host controller driver to initiate the software reset of the host controller. The system is moved to the USB Suspend state in which most of the operational registers are reset except for the next state regardless of the functional state of the host controller. For example, an access without the IR field in the HcControl register and host bus are allowed. This bit is cleared by the host controller upon completion of the reset operation. The reset operation must be completed within 10 $\mu$ s. When this bit is set, it does not cause any reset to the route hub and the next reset signal is not output to the downstream port.
				<ul><li>0: Cleared by the host controller at the completion of the reset operation</li><li>1: USB Suspend state</li></ul>

www.DNote:eet\*U.TD is Transfer Descriptor.

#### 19.3.4 HcInterruptStatus Register (HISR)

HISR indicates the status in various events that cause hardware interrupts. When an event occurs, the host controller sets the corresponding bit in this register. When the bit is set to 1, a hardware interrupt is generated while an interrupt is enabled and the MIE bit is set in the HcInterruptEnable register (see section 19.3.5, HcInterruptEnable Register (HIER)). When an interrupt occurs, the exception code (H'A00) of the host controller interrupt (USBHI) is set in the interrupt event register 2 (INTEVT2) and the exception handling is started. For details on the interrupt event register 2 (INTEVT2), see section 4, Exception Handling, and for details on the exception code and interrupt processing of the host controller interrupt (USBHI), see section 8, Interrupt Controller (INTC).

The host controller driver clears a specified bit in this register by writing 1 in the bit position to be cleared. The host controller driver cannot set any of these bits. The host controller never clears bits.

www.DataSheet4U.com

Bit	Bit Name	Initial Value	R/W	Description
31	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to this bit.
30	OC	0	R/W	Ownership Change
				This bit is set when the OCR bit in the HcCommandStatus register is set by the host controller driver. This event generates a system management interrupt (SMI) at once when not masked. When there is no SMI pin, this bit is cleared to 0.
				O: The OCR bit in the HcCommandStatus register is not set.  1: The OCR bit in the HcCommandStatus register is set.
20 to 7		All O	D	1: The OCR bit in the HcCommandStatus register is set.
29 to 7	_	All 0	R	Reserved
ataSheet4				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
6	RHSC	0	R/W	Root Hub Status Change
				This bit is set when the content of the HcRhStatus register or the content of any HcRhPortStatus register [Number of Downstream Port] has changed.
				<ul><li>0: The content of the HcRhStatus register or HcRhPortStatus register is not changed.</li><li>1: The content of the HcRhStatus register or HcRhPortStatus register is changed.</li></ul>
5	FNO	0	R/W	Frame Number Overflow
				This bit is set when MSB (bit 15) in the HcFmNumber register changes value from 0 to 1 or from 1 to 0 or after HccaFrameNumber is updated.
				<ul><li>0: MSB in the HcFmNumber register or HccaFrameNumber is not updated.</li><li>1: MSB in the HcFmNumber register or HccaFrameNumber is updated.</li></ul>
4	UE	0	R/W	Unrecoverable Error
				This bit is set when the host controller detects a system error that is not related to USB. The host controller driver clears this bit after the host controller is reset.
				System error has not generated yet.     System error is detected.

Bit	Bit Name	Initial Value	R/W	Description
3	RD	0	R/W	Resume Detected
				This bit is set when the host controller detects that the USB device outputs a resume signal. This bit is not set when the host controller driver sets the USB Resume state.
				<ul><li>0: The resume signal is not detected.</li><li>1: The resume signal is detected.</li></ul>
2	SF	0	R/W	Start of Frame
				This bit is set by the host controller when each frame starts and after HccaFrameNumber is updated. The host controller simultaneously generates the SOF token.
				<ul><li>0: Each frame has not initiated or HccaFrameNumber is not updated.</li><li>1: Initiation of each frame and updating of HccaFrameNumber</li></ul>
DataShee	<sup>14</sup> WDH	0	R/W	Write back Done Head
				This bit is set immediately after the host controller has written HcDoneHead to HccaDoneHead. HccaDoneHead is not updated until this bit is cleared. The host controller driver should clear this bit only after the content of HccaDoneHead has been stored.
				When cleared after set to 1.     When HcDoneHead is written to HccaDoneHead.
0	SO	0	R/W	Scheduling Overrun
				This bit is set when the USB schedule has overrun after HccaFrameNumber has updated in the current frame. SchedulingOverrun also increments the SOC0 and SOC1 bits in the HcCommandStatus register.
				<ul><li>0: The USB schedule has not overrun.</li><li>1: The USB schedule has overrun.</li></ul>

#### 19.3.5 HcInterruptEnable Register (HIER)

Each enable bit in HIER controls whether to generate an interrupt by an event related to the HcInterruptStatus register. A hardware interrupt is requested to the CPU when an event bit in the HcInterruptStatus register is set, a corresponding bit in the HcInterruptEnable register is set, and the MasterInterruptEnable (MIE) bit is set. As a result, the exception code (H'A00) of the host controller interrupt (USBHI) is set in the interrupt event register 2 (INTEVT2) and the exception handling is started (the USBHI exception code is used in common regardless of the content of the interrupt generation event). Therefore, the USBHI exception code can be used when an interrupt generation is detected by the host controller driver. For details on the interrupt event register 2 (INTEVT2), see section 4, Exception Handling, and for details on the exception code and interrupt processing of the host controller interrupt (USBHI), see section 8, Interrupt Controller (INTC).

Writing 1 in this register sets the corresponding bit, while writing 0 does not change it. When the specified bit needs to be set, writing data in which only the corresponding bit is 1 enables the bit to be set independently without checking the states of other bits.

HIER is in conjunction with the HcInterruptDisable register which is described later. Therefore when a specific bit needs to be cleared to 0, writing 1 to the corresponding bit in the HcInterruptDisable register automatically clears the corresponding bit in this register.

Bit	Bit Name	Initial Value	R/W	Description
31	MIE	0	R/W	Master Interrupt Enable
				When this bit is set to 1, an interrupt generation by the event specified in another bit in this register is enabled. This is used by the host controller driver so that the master interrupt is enabled. When 1 is written to the MIE bit in the HcInterruptDisable register, this bit is cleared to 0.
				<ul><li>0: This bit is ignored.</li><li>1: Enables interrupt generation due to the event specified by other bit.</li></ul>
30	OC	0	R/W	Ownership Change Interrupt Enable When this bit is set to 1, an interrupt generation by the Ownership Change event is enabled. When 1 is written to the OC bit in the HcInterruptDisable register, this bit is cleared to 0.
				O: This bit is ignored. Enables interrupt generation due to the Ownership Change event.

Bit	Bit Name	Initial Value	R/W	Description
29 to 7	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
6	RHSC	0	R/W	Root Hub Status Change Interrupt Enable
				When this bit is set to 1, an interrupt generation by the Root Hub Status Change event is enabled. When 1 is written to the RHSC bit in the HcInterruptDisable register, this bit is cleared to 0.
				O: This bit is ignored. Enables interrupt generation due to the Root Hub Status Change event.
5	FNO	0	R/W	Frame Number Overflow Interrupt Enable
	t4U.com			When this bit is set to 1, an interrupt generation by the Frame Number Overflow event is enabled. When 1 is written to the FNO bit in the HcInterruptDisable register, this bit is cleared to 0.
				O: This bit is ignored. Enables interrupt generation due to the Frame Number Overflow event.
4	UE	0	R/W	Unrecoverable Error Interrupt Enable
				When this bit is set to 1, an interrupt generation by the Unrecoverable Error event is enabled. When 1 is written to the UE bit in the HcInterruptDisable register, this bit is cleared to 0.
				O: This bit is ignored. Enables interrupt generation due to the Unrecoverable Error event.
3	RD	0	R/W	Resume Detected Interrupt Enable When this bit is set to 1, an interrupt generation by the Resume Detected event is enabled. When 1 is written to the RD bit in the HcInterruptDisable register, this bit is cleared to 0.
				O: This bit is ignored. Enables interrupt generation due to the Resume Detected event.

		Initial		
Bit	Bit Name	Value	R/W	Description
2	SF	0	R/W	Start of Frame Interrupt Enable
				When this bit is set to 1, an interrupt generation by the Start of Frame event is enabled. When 1 is written to the SF bit in the HcInterruptDisable register, this bit is cleared to 0.
				0: This bit is ignored.
				<ol> <li>Enables interrupt generation due to the Start of Frame event.</li> </ol>
1	WDH	0	R/W	WriteBack Done Head Interrupt Enable
				When this bit is set to 1, an interrupt generation by the WriteBack Done Head event is enabled. When 1 is written to the WDH bit in the HcInterruptDisable register, this bit is cleared to 0.
taSheet4I				<ul><li>0: This bit is ignored.</li><li>1: Enables interrupt generation due to the WriteBack Done Head event.</li></ul>
0	SO	0	R/W	Scheduling Overrun Interrupt Enable
				When this bit is set to 1, an interrupt generation by the SchedulingOverrun event is enabled. When 1 is written to the SO bit in the HcInterruptDisable register, this bit is cleared to 0.
				<ul><li>0: This bit is ignored.</li><li>1: Enables interrupt generation due to the SchedulingOverrun event.</li></ul>

#### 19.3.6 HcInterruptDisable Register (HIDR)

Each disable bit in HIDR controls whether to mask an interrupt by an event related to the HcInterruptStatus register. A hardware interrupt is not requested to the CPU when an event bit in the HcInterruptStatus register is set and a corresponding bit in the HcInterruptDisable register is set or the MIE bit in the HcInterruptDisable register is set.

Writing 1 in this register clears the corresponding bit in the HcInterruptEnable register (disable state), while writing 0 does not change it. When the specified bit is disabled, writing data in which only the corresponding bit is 1 enables the bit to be disabled independently without checking the states of other bits.

HIDR is in conjunction with the HcInterruptEnable register which is described before. Therefore when the specified bit needs to be cleared to 0 (enable state), writing 1 in the corresponding bit in the HcInterruptEnable register enables the corresponding bit in this register to be automatically cleared to 0. When this register is read, the current value of the HcInterruptEnable register is returned.

ww.DataSheet4U.com

<b>5</b>	<b>5</b>	Initial	D.044	~
Bit	Bit Name	Value	R/W	Description
31	MIE	0	R/W	Master Interrupt Disable
				When this bit is set to 1, an interrupt generation by the event specified in another bit in this register is masked. When 1 is written to the MIE bit in the HcInterruptEnable register, this bit is cleared to 0.
				0: This bit is ignored.
				<ol> <li>Disables interrupt generation due to the event specified by other bit.</li> </ol>
30	ОС	0	R/W	Ownership Change Interrupt Disable
				When this bit is set to 1, an interrupt generation by the Ownership Change event is masked. When 1 is written to the OC bit in the HcInterruptEnable register, this bit is cleared to 0.
				0: This bit is ignored.
				Disables interrupt generation due to the Ownership Change event.
29 to 7	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
				willen to these bits.

Bit	Bit Name	Initial Value	R/W	Description
6	RHSC	0	R/W	Root Hub Status Change Interrupt Disable
				When this bit is set to 1, an interrupt generation by the Root Hub Status Change event is masked. When 1 is written to the RHSC bit in the HcInterruptEnable register, this bit is cleared to 0.
				O: This bit is ignored. Disables interrupt generation due to the Root Hub Status Change event.
5	FNO	0	R/W	Frame Number Overflow Interrupt Disable
				When this bit is set to 1, an interrupt generation by the Frame Number Overflow event is masked. When 1 is written to the FNO bit in the HcInterruptEnable register, this bit is cleared to 0.

4	UE	0	R/W	Unrecoverable Error Interrupt Disable
				When this bit is set to 1, an interrupt generation by the Unrecoverable Error event is masked. When 1 is written to the UE bit in the HcInterruptEnable register, this bit is cleared to 0.
				<ul><li>0: This bit is ignored.</li><li>1: Disables interrupt generation due to the Unrecoverable Error event.</li></ul>
3	RD	0	R/W	Resume Detected Interrupt Disable When this bit is set to 1, an interrupt generation by the Resume Detected event is masked. When 1 is written to the RD bit in the HcInterruptEnable register, this bit is cleared to 0.
				This bit is ignored.     Disables interrupt generation due to the Resume Detected event.
2	SF	0	R/W	Start of Frame Interrupt Disable When this bit is set to 1, an interrupt generation by the Start of Frame event is masked. When 1 is written to the SF bit in the HcInterruptEnable register, this bit is cleared to 0.
				O: This bit is ignored. Disables interrupt generation due to the Start of Frame event.

		Initial		
Bit	Bit Name	Value	R/W	Description
1	WDH	0	R/W	WriteBack Done Head Interrupt Disable
				When this bit is set to 1, an interrupt generation by the WriteBack Done Head event is masked. When 1 is written to the WDH bit in the HcInterruptEnable register, this bit is cleared to 0.
				O: This bit is ignored.  Disables interrupt generation due to the WriteBack  Done Head event.
0	SO	0	R/W	Scheduling Overrun Interrupt Disable
				When this bit is set to 1, an interrupt generation by the SchedulingOverrun event is masked. When 1 is written to the SO bit in the HcInterruptEnable register, this bit is cleared to 0.
	et4U.com			<ul><li>0: This bit is ignored.</li><li>1: Disables interrupt generation due to the SchedulingOverrun event.</li></ul>

#### 19.3.7 HcHCCA Register (HHCCAR)

HHCCAR includes physical addresses in the host controller communication area. The host controller driver determines the alignment limitation by writing 1 to all bits in the HcHCCA register and by reading the content of the HcHCCA register. Alignment is determined by checking the number of 0 in the lower bits. The minimum alignment is 256 bytes. Consequently, bits 0 to 7 must always be 0 when they are read. This area is used to retain the control structure and interrupt table that are accessed by the host controller and host controller driver.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	HCCA	All 0	R/W	These bits are physical addresses in the Host Controller Communication Area.
7 to 0	_	All 0	R	These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

# 19.3.8 HcPeriodCurrentED Register (HPCEDR)

HPCEDR includes a physical address of the current isochronous ED or interrupt ED.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	PCED	All 0	R	Period Current ED
				These bits are physical addresses of the current isochronous ED or interrupt ED.
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

# 19.3.9 HcControlHeadED Register (HCHEDR)

HCHEDR includes a physical address of the first ED in the control list.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 4	CHED	All 0	R/W	Control Head ED
				These bits are physical addresses of the first ED in the control list.
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

# 19.3.10 HcControlCurrentED Register (HCCEDR)

HCCEDR includes a physical address of the current ED in the control list.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	CCED	All 0	R/W	Control Current ED
				These bits are physical addresses of the current ED in the control list.
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

#### 19.3.11 HcBulkHeadED Register (HBHEDR)

HBHEDR includes a physical address of the first ED in the bulk list.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 4	BHED	All 0	R/W	Bulk Head ED
				These bits are physical addresses of the first ED in the bulk list.
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

#### 19.3.12 HcBulkCurrentED Register (HBCEDR)

WWW.DHBCEDR includes a physical address of the current ED in the bulk list. When the bulk list is supplied by the round robin method, endpoints are ordered to the list according to these insertions.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	BCED	All 0	R/W	Bulk Current ED
				These bits are physical addresses of the current ED in the bulk list.
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

# 19.3.13 HcDoneHeadED Register (HDHEDR)

HDHEDR includes a physical address of the finally completed TD added to the done queue. The host controller driver need not read this register so that the content is written to HCCA periodically in normal operation.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	DH	All 0	R	Done Head
				These bits are physical addresses of the finally completed TD added to the done queue.

www.DataSheet4U.com

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

#### 19.3.14 HcFmInterval Register (HFIR)

HFIR includes a 14-bit value indicating the bit time interval of the frame (i.e., between two serial SOFs) and a 15-bit value indicating the maximum packet size at a full speed that is transmitted and received by the host controller without causing SchedulingOverrun. The host controller driver adjusts the frame interval minutely by writing a new value over the current value in each SOF.

Bit	Bit Name	Initial Value	R/W	Description
Dat <b>35</b> heet4	URbim	0	R/W	Frame Interval Toggle
				This bit is toggled by the host controller driver whenever it loads a new value into the Frame Interval bits.
30	FSMPS14	0	R/W	FSLargest Data Packet
29	FSMPS13	0	R/W	These bits specify a value which is loaded into the
28	FSMPS12	0	R/W	Largest Data Packet Counter at the beginning of each frame. The counter value expresses the largest data
27	FSMPS11	0	R/W	amount of the bit that can be transmitted and received in
26	FSMPS10	0	R/W	one transaction by the host controller at any given time
25	FSMPS9	0	R/W	without causing SchedulingOverrun. The field value is calculated by the host controller driver.
24	FSMPS8	0	R/W	calculated by the host controller driver.
23	FSMPS7	0	R/W	
22	FSMPS6	0	R/W	
21	FSMPS5	0	R/W	
20	FSMPS4	0	R/W	
19	FSMPS3	0	R/W	
18	FSMPS2	0	R/W	
17	FSMPS1	0	R/W	
16	FSMPS0	0	R/W	
15, 14	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

Bi	t Bit Name	Initial Value	R/W	Description
13		1	R/W	Frame Interval
12	FI12	0	R/W	These bits specify the interval between two serial SOFs
11	FI11	1	R/W	with bit times. The nominal value is set to H'2EDF
10	FI10	1	R/W	(11999).
9	FI9	1	R/W	The host controller driver must store the current value of this field before resetting the host controller. With this
8	FI8	0	R/W	procedure, this bit is reset to its nominal value by the host
7	FI7	1	R/W	controller by setting the HCR bit in the HcCommandStatus register. The host controller driver
6	FI6	1	R/W	can select to restore the stored value at the completion of
5	FI5	0	R/W	the reset sequence.
4	FI4	1	R/W	
3	FI3	1	R/W	
2	FI2	1	R/W	
1 v Data	FI1 Sheet4U.com	1	R/W	
0	FIO	1	R/W	

# 19.3.15 HcFmRemaining Register (HFRR)

HFRR is a 14-bit down counter indicating the bit time remaining in the current frame.

Bit	Bit Name	Initial Value	R/W	Description
31	FRT	0	R	Frame Remaining Toggle
				This bit is always loaded from the FIT bit in the HcFmInterval register when the FR bits reach 0. This bit is used by the host controller driver for synchronization between the FrameInterval and FrameRemaining registers.
30 to 14	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
13	FR13	0	R	Frame Remaining
ita2heet4U	FR12	0	R	These counters are decremented at each bit time. When
11	FR11	0	R	these counters reach 0, these counters are reset by
10	FR10	0	R	loading the value of the Frame Interval bit specified in the HcFmInterval register at the next bit time boundary.
9	FR9	0	R	When the host controller transits to the USB Operational
8	FR8	0	R	state, it reads the FI bits in the HcFmInterval register again and uses the updated value from the next SOF.
7	FR7	0	R	again and uses the updated value from the fiext 501.
6	FR6	0	R	
5	FR5	0	R	
4	FR4	0	R	
3	FR3	0	R	
2	FR2	0	R	
1	FR1	0	R	
0	FR0	0	R	

# 19.3.16 HcFmNumber Register (HFNR)

HFNR is a 16-bit counter. It indicates the reference of timing between events occurring in the host controller and host controller driver. The host controller driver uses a 16-bit value specified in this register and generates a 32-bit frame number without necessity for a frequent access to the register.

			Initial		
	Bit	Bit Name	Value	R/W	Description
	31 to 16	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
	15	FN15	0	R	Frame Number
	14	FN14	0	R	These bits are incremented when the HcFmRemaining
	13	FN13	0	R	register is reloaded. The count will return to H'0 after reaching H'FFFF.
/.D	a <mark>12</mark> Sheet4	FN12	0	R	When the host controller transits to the USB Operational
	11	FN11	0	R	state, these bits are automatically incremented. After the
	10	FN10	0	R	host controller increments the FN15 to FN0 bits and
	9	FN9	0	R	sends SOF in each frame boundary, the content is written to HCCA before the host controller reads the first ED in
	8	FN8	0	R	the frame. After writing to HCCA, the host controller sets
	7	FN7	0	R	the SF bit in the HcInterruptStatus register.
	6	FN6	0	R	
	5	FN5	0	R	
	4	FN4	0	R	
	3	FN3	0	R	
	2	FN2	0	R	
	1	FN1	0	R	
	0	FN0	0	R	

# 19.3.17 HcPeriodicStart Register (HPSR)

HPSR has a 14-bit programmable value, which determines the earliest time when the host controller should start to process the periodic list.

		Initial		
Bit	Bit Name	Value	R/W	Description
31 to 14	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
13	PS13	0	R/W	Periodic Start
12	PS12	0	R/W	This field is cleared after the hardware reset. Then this
11	PS11	0	R/W	field is set by the host controller driver while the host controller performs initial settings. This value is roughly
10	PS10	0	R/W	calculated as 10% off from the HcFmInterval register. The
9	PS9	0	R/W	normal value is H '2A2F.
taSheet4L 8	PS8	0	R/W	When the HcFmRemaining register reaches the specified
7	PS7	0	R/W	value, the processing of the periodic list has a higher priority than the control/bulk processing. Consequently,
6	PS6	0	R/W	the host controller starts to process the periodic list after
5	PS5	0	R/W	the completion of the current control/bulk transaction.
4	PS4	0	R/W	
3	PS3	0	R/W	
2	PS2	0	R/W	
1	PS1	0	R/W	
0	PS0	0	R/W	

# 19.3.18 HcLSThreshold Register (HLSTR)

HLSTR includes an 12-bit value that is used by the host controller to determine whether or not to authorize the transfer of the LS packed 8 bytes in maximum before EOF. The host controller and host controller driver cannot change this value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
11	LST11	0	R/W	LSThreshold
10	LST10	1	R/W	This field contains a value to be compared with the FR
9	LST9	1	R/W	bits prior to the beginning of low-speed transaction.
8	LST8	0	R/W	The transaction is started only when the FR bit value is
ataSheet4	LST7	0	R/W	beyond the value of this bit. The value is calculated by the host controller driver considering the transmission
6	LST6	0	R/W	and set-up overhead.
5	LST5	1	R/W	
4	LST4	0	R/W	
3	LST3	1	R/W	
2	LST2	0	R/W	
1	LST1	0	R/W	
0	LST0	0	R/W	

# 19.3.19 HcRhDescriptorA Register (HRDRA)

HRDRA is the first register of two registers describing the features of the root hub. The descriptor length (11), descriptor type (T.B.D), and the hub controller current bit (0) of the class descriptor of the hub are emulated by the host controller driver. All other bits are placed in the HcRhDescriptorA register and HcRhDescriptorB register.

Bit	Bit Name	Initial Value	R/W	Description
31	POTPGT7	0	R/W	Power On To Power Good Time
30	POTPGT6	0	R/W	These bits specify the waiting time until a host controller
29	POTPGT5	0	R/W	driver access the power-on port of the root hub. The bits are implementation specific. The unit of time is 2
28	POTPGT4	0	R/W	ms. The time is calculated as POTPGT $\times$ 2 ms.
27	POTPGT3	0	R/W	
26	POTPGT2	0	R/W	
<b>25</b> taSheet4U	POTPGT1	1	R/W	
24	POTPGT0	0	R/W	
23 to 13	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
12	NOCP	1	R/W	No Over Current Protection
				This bit selects how the overcurrent status of the root hub port is reported. When this bit is cleared, the OCPM bit specifies global report or report at each port.
				<ul><li>0: Overcurrent status is collectively reported for all downstream ports.</li><li>1: Overcurrent protection is not supported.</li></ul>
11	ОСРМ	0	R/W	Over Current Protection Mode
		·		This bit selects how the overcurrent status in the roothub port is reported. At reset, this bit reflects the same mode as the PSM bit. When the NOCP bit is cleared, this bit is valid.
				<ul><li>0: Overcurrent status is collectively reported for all downstream ports.</li><li>1: Overcurrent status is reported for each port.</li></ul>
10	DT	0	R	DeviceType
				This bit indicates that the route hub is not a compound device. This bit should always be set to 0.

			Initial		
	Bit	Bit Name	Value	R/W	Description
	9	NPS	1	R/W	No Power Switching
					This bit selects whether the power switching is supported or ports are always power-supplied. This bit is implementation specific. When this bit is cleared, the PSM bit specifies the global/port switching.
					Note: Because the initial value is 1, first clear this bit (write 0 with the host controller driver) to enable power switching of the port.
					O: Ports can be power-switched.  Ports are always powered on when the host controller is powered on.
	8	PSM	0	R/W	Power Switching Mode
					This bit specifies how the power switching of the root-hub port is controlled. This bit is implementation specific. This bit is valid only when the NPS bit is cleared.
w.C	)ataSheet	4U.com			<ul> <li>0: All ports are simultaneously power-supplied.</li> <li>1: Each port is power-supplied individually. In this mode, the port power is controlled with either of global/port switching. When the PPCM bit in the HcRhDescriptorB register is set, the port is reacted only to the port-power command (set/clear port power). When the port mask is cleared, the port is controlled only by the global power-switch (set/clear global power).</li> </ul>
	7	NDP7	0	R	Number Downstream Ports
	6	NDP6	0	R	These bits specify the number of downstream ports
	5	NDP5	0	R	supported by the root hub. These bits are implementation specific. The minimum number of ports is 1. The
	4	NDP4	0	R	maximum number of ports which are supported by the
	3	NDP3	0	R	OpenHCI is 15.
	2	NDP2	0	R	
	1	NDP1	1	R	
	0	NDP0	0	R	

# 19.3.20 HcRhDescriptorB Register (HRDRB)

HRDRB is the second register of two registers describing the features of the root hub. These bits must be set during the initial setting so as to correspond to the system implementation.

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	3 —	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
17	PPCM	0	R/W	Port Power Control Mask
)ataSheet4				This bit indicates whether the port is influenced by the global power-control command when the PSM bit in the HcRhDescriptorA register is set. When this bit is set, the power state of the port is affected by the power control at each port (set/clear port power). When this bit is cleared, the port is controlled by the global power switch (set/clear global power). If the device is placed in global switching mode (PSM bit = 0), this bit is not valid.
				Note: Clear the NPS bit in the HcRhDescriptorA register so that the power to all ports is off (PortPowerStatus = 0), then set this bit.
				0: Ports are controlled by the global power switch.
				1: Port#1 is affected by the power control at each port.
16 to 2	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
1	DR	0	R/W	Device Removable
				This bit is dedicated to the ports of the root hub. When this bit is cleared, the set device becomes removable. When this bit is set, do not remove the set device.
				0: Device attached to port#1 is removable.
				1: Device attached to port#1 is not removable.
0	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to this bit.

# 19.3.21 HcRhStatus Register (HRSR)

HRSR is divided into two parts. The lower word of a longword indicates the hub status bits and the upper word indicates the hub status change bit. The reserved bits should be set to 0.

Bit	Bit Name	Initial Value	R/W	Description
31	CRWE	0	W	Clear Remote Wakeup Enable
				Writing 1 clears this bit. When this bit is set to 0, this bit is not cleared.
30 to 18	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
17	OCIC	0	R/W	Over Current Indicator Change
.DataSheet <sup>z</sup>	IU.com			When the OCI field in this register is changed, this bit is set by the host controller. Writing 1 by the host controller driver clears this bit. When this bit is set to 0, this bit is not cleared.
16	LPSC	0	R/W	(Read) Local Power Status Change
				The root hub does not support the local power status function. Therefore, this bit is always read as 0.
				(Write) Set Global Power
				This bit is written to 1 to power on (sets the PPS bit in the HcRhPortStatus register) all ports in global power mode (PSM bit in the HcRhDescriptorA register = 0). This bit sets the PPS bit only to the port in which the PPCM bit in the HcRhDescriptorB register is not set in power mode at each port. When 0 is written to, this bit is not cleared.
15	DRWE	0	R/W	(Read) Device Remote Wakeup Enable
				This bit enables the CSC bit in the HcRhPortStatus register as a resume event and generates the state transition from USB Suspend to USB Resume and the Resume Detected interrupt.
				0: Connect Status Change is not the Remote Wakeup event.
				1: Connect Status Change is the Remote Wakeup event.
				(Write) Set Remote Wakeup Enable
				Writing 1 sets this bit. When 0 is written to, this bit is not set.

Bit	Bit Name	Initial Value	R/W	Description
14 to 2	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
1	OCI	0	R/W	Over Current Indicator
				This bit reports the overcurrent condition when the globa report is performed. When this bit is set, an overcurrent condition exists. When this bit is cleared, all power operations are normal. This bit is always 0 when the overcurrent protection at each port is carried out.
				<ul><li>0: All power operations are normal.</li><li>1: An overcurrent condition exists.</li></ul>
0	LPS	0	R/W	(Read) Local Power Status
				The root hub does not support the local power status function. Therefore, this bit is always read as 0.
ataSheet4				(Write) Clear Global Power
				This bit is written to 1 to power off (clears the PPS bit in the HcRhPortStatus register) all ports in global power mode (PSM bit in the HcRhDescriptorA register = 0).
				In power mode at each port, the PPS bit is cleared to the port in which the PPCM bit in the HcRhDescriptorB register is not set. When 0 is written to, this bit is invalid.

# 19.3.22 HcRhPortStatus Register (HRPSR)

HRPSR is used for base-controlling each port and to report the port event. The lower word is used to reflect the port status while the upper word reflects the status change. Some status bits have special writing (see below). If the transaction (token that passes the hand shake) is in progress while a write to ChangePortStatus occurs, the resultant port status change must be postponed until the completion of the transaction. Always write reserved bits to 0.

	Bit	Bit Name	Initial Value	R/W	Description
	31 to 21	_	All 0	R	Reserved
					These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
	20	PRSC	0	R/W	Port Reset Status Change
v.D					This bit is set when the 10 ms port reset signal has completed. Writing 1 by the host controller driver clears this bit. When this bit is written to 0, this bit is not cleared.
					<ul><li>0: Port reset is not completed.</li><li>1: Port reset is completed.</li></ul>
	19	OCIC	0	R/W	Port Over Current Indicator Change
					This bit is valid when an overcurrent condition is reported on the base of each port. This bit is set when the root hub changes the POCI bit. Writing 1 by the host controller driver clears this bit. When this bit is written to 0, this bit is not cleared.
					<ul><li>0: Port Over Current Indicator has not changed.</li><li>1: Port Over Current Indicator has changed.</li></ul>
	18	PSSC	0	R/W	Port Suspend Status Change
					This bit is set when all resume sequences have completed. These sequences include 20 ms resume pulse, LS EOP, and 3 ms resychronization delay. Writing 1 by the host controller driver clears this bit. When this bit is written to 0, this bit is not cleared. When the PRSC bit is set, this bit is cleared.
					0: Resume sequence has not completed.
					1: Resume sequence has completed.

Bit	Bit Name	Initial Value	R/W	Description
17	PESC	0	R/W	Port Enable Status Change
				This bit is set when the PES bit is cleared due to a hardware event. This bit is not set by the change of writing of the host controller driver. Writing 1 by the host controller driver clears this bit. When this bit is written to 0, this bit is not cleared.
				<ul><li>0: Port Enable Status has not changed.</li><li>1: Port Enable Status has changed.</li></ul>
16	CSC	0	R/W	Connect Status Change
taSheet4L				This bit is set whenever the connection or disconnection event occurs. Writing 1 by the host controller driver clears this bit. When this bit is written to 0, this bit is not cleared. If the CCS bit is cleared when Set Port Reset, Set Port Enable, or Set Port Suspend is written to, writing when the power supply of the port is disconnected does not occur, so this bit is set to report the driver to re-evaluate the connection status.
				Note: If the DR bit in the HcRhDescriptorB register is set, this bit is set only after the root hub reset to report the system that a device can be attached.
				<ul><li>0: Current Connect Status has not changed.</li><li>1: Current Connect Status has changed.</li></ul>
15 to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.
9	LSDA	0	R/W	(Read) Low Speed Device Attached
				This bit indicates the speed of the device attached to this port. When this bit is set, a low-speed device is attached to this port. When this bit is cleared, a full-speed device is attached to this port. This bit is valid only when the CCS bit is set.
				<ul><li>0: A full-speed device is attached.</li><li>1: A low-speed device is attached.</li></ul>
				(Write) Clear Port Power
				Writing 1 by the host controller driver clears the PPS bit. When this bit is written to 0, this bit is not cleared.

		Initial		
Bit	Bit Name	Value	R/W	Description
8	PPS	1	R/W	(Read) Port Power Status
				This bit reflects the power status of the port regardless of power switching mode to be executed. However, because the initial value of the No Power Switching bit in the HcRhDescriptorA register is 1, this bit is first fixed to 1. The No Power Switching bit must first be cleared when power is switched, as shown below.
				When an overcurrent condition is detected, this bit is cleared. Writing Set Port Power or Set Global Power by the host controller driver sets this bit. Also, writing Clear Port Power or Clear Global Power by the host controller driver clears this bit.
	et4U.com			The PSM bit in the HcRhDescriptorA register and the PPCM bit in the HcRhDescriptorB register determine which power control switch can be used. Only Set/Clear Global Power controls this bit in global switching mode (PSM bit = 0). If the PPCM bit of that port is set in power switching mode (PSM bit = 1), only the Set/Clear Port Power command is enabled. If the mask is not set, only the Set/Clear Global Power command is enabled. When the port power is disabled, the CCS, PES, PSS, and PRS bits are reset.
				Note: If power switching mode is not supported, this bit is always read as 1.
				0: Port power is off.
				1: Port power is on.
				(Write) Set Port Power
				Writing 1 by the host controller driver sets the PPS bit. When this bit is written to 0, this bit is not set.
7 to 5	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. The operation is not guaranteed if 1 is written to these bits.

	Bit	Bit Name	Initial Value	R/W	Description
-	4	PRS	0	R/W	(Read) Port Reset Status
					When this bit is set by writing to Set Port Reset, the port reset signal is output. This bit is cleared when the PRSC bit is set upon completion of a reset. When the CCS bit is cleared, this bit is not set.
					<ul><li>0: Port reset signal is not active.</li><li>1: Port reset signal is active.</li></ul>
					(Write) Set Port Reset
					Writing 1 by the host controller driver sets the port reset signal. When this bit is written to 0, this bit is not set. When the CCS bit is cleared, this write does not set the PRS bit, instead, sets the CSC bit. This reports a reset of the disconnection port to the driver.
	3	POCI	0	R/W	(Read) Port Over Current Indicator
.Dat	DataSheet4U.com				This bit is valid only when a root hub is placed in such a way that an overcurrent condition is reported on the base of each port. If the overcurrent report at each port is not supported, this bit is cleared to 0. If this bit is cleared, all power controls are normal in this port. If this bit is set, an overcurrent state exists in this port. This bit always reflects an overcurrent input signal.
					<ul><li>0: No overcurrent state.</li><li>1: Overcurrent state is detected.</li></ul>
					(Write) Clear Suspend Status
					Writing 1 by the host controller driver initiates a resume. When this bit is written to 0, this bit is invalid. If the PSS bit is set, a resume is initiated.

Bit	Bit Name	Initial Value	R/W	Description
2	PSS	0	R/W	(Read) Port Suspend Status
				This bit indicates that the port is under the process to suspend or during the resume sequence. Writing Set Suspend State sets this bit and setting the PSSC bit clears this bit at the end of the resume interval. If the CCS bit is cleared, this bit cannot be set. When the PRSC bit is set upon completion of the port reset or the host controller is placed in the USB resume state, this bit is cleared. If an upstream resume is in progress, it is transmitted to the host controller.
				O: Port is not suspended. I: Port is suspended.
				(Write) Set Port Suspend
	et4U.com			Writing 1 by the host controller driver sets the PSS bit. When this bit is written to 0, this bit is not set. In addition, when the CCS bit is cleared, the PSS bit is not set by this writing. Instead, the CSC bit is set. This reports the suspended state of the disconnection port to the driver.
1	PES	0	R/W	(Read) Port Enable Status
				This bit indicates whether the port is enabled or disabled. The root hub clears this bit when the overcurrent condition and an operational bus error such as disconnect event, power-off switch, or babble are detected. The PESC bit is set by this change. This bit is set by writing Set Port Enable and cleared by writing Clear Port Enable. This bit cannot be set when the CCS bit is cleared. In addition, this bit is set upon completion of the port reset by which the PRSC bit is set, or upon completion of the port suspend by which the PSSC bit is set.
				0: Port disabled. 1: Port enabled.
				(Write) Set Port Enable
				Writing 1 by the host controller driver sets the PES bit. When this bit is written to 0, this bit is not set. If the CCS bit is cleared, this writing does not set the PES bit, instead, sets the CSC bit. This reports the driver that the disconnection port has been tried to be enabled.

		Initial		
Bit	Bit Name	Value	R/W	Description
0	CCS	0	R/W	(Read) Current Connect Status
				This bit indicates the current status of the downstream port.
				Note: If the set device is not removable (DeviceRemovable), this bit is always read as 1.
				O: No device connected. Device connected.
				(Write) Clear Port Enable
				Writing 1 by the host controller driver clears the PES bit. When this bit is written to 0, this bit is not cleared. The CCS bit is not affected by any writing.

# 19.4 Data Storage Format of USB Host Controller

### 19.4.1 Storage Format of Transferred Data

The data storage format (endian) of the USB host controller is in conjunction with the CPU endian specification by the MD5 pin. Therefore, when the CPU is operated as big endian, transfer data of the USB host controller must be treated in big-endian order. When the CPU is operated as little endian, transfer data of the USB host controller must be treated in little-endian order.

## 19.4.2 Storage Format of Descriptor

ED (endpoint descriptor) and TD (transfer descriptor) that define each transfer transaction of the USB host controller must be aligned so that each Dword corresponds to the longword boundary (addresses 4n + 3) of the memory. In this case, the difference of endian has no influence.

# 19.5 Usage Restrictions of USB Host Controller

#### 19.5.1 Restriction of Reset Control

Following procedure should be used when the software reset is issued (the HCR bit of the HCSR register is set to 1) while USB state is Operational, or when the USB state is shifted from the Operational state to the Reset state (the HCFS1/0 bit of the HCTLR register is cleared to 00).

- 1. Each list processing is discontinued. (The BLE bit, the CLE bit, the IE bit, and the PLE bit of the HCTLR register are cleared to 0.)
- 2. Wait until the SOF interrupt from the USB host controller is detected twice. (SF bit interrupt of HISR register)
- 3. Put the USB into the Suspend state by setting the HCFS1/0 bits of the HCTLR register to 11.
- 4. The reset processing is executed.

# Section 20 USB Function Controller (USBF)

This LSI incorporates an USB function controller (USBF).

#### 20.1 Features

• UDC (USB device controller) supporting USB 1.1 processes incorporated USB protocol automatically.

Automatic processing of USB standard commands for endpoint 0 (some commands and class/vendor commands require decoding and processing by firmware)

• Transfer speed: Full-speed

An arbitrary endpoint configuration can be set by specifying the endpoint number used by the USB host and the endpoint FIFO number (transfer method and transfer direction are fixed) provided by this USB function controller via the EPIRn0 to EPIRn5 registers.

DataSheet4U.co Endpoint Name	Abbreviation	Endpoint FIFO Number	Transfer Type	Maximum Packet Size	FIFO Buffer Capacity (Byte)	DMA Transfer	Application
Endpoint 0	EP0s	H'00	Setup	8	8	_	Emulation
	EP0i	H'00	Control-in	64	64	_	-
	EP0o	H'00	Control-out	64	64	_	-
Endpoint 1	EP1	H'01	Interrupt-in	16	16	_	Modem,
Endpoint 2i	EP2i	H'02	Bulk-in	64	128	Possible	packet
Endpoint 2o	EP2o	H'03	Bulk-out	64	128	Possible	-
Endpoint 3i	EP3i	H'05	Isochronous-in	64	128	_	AT
Endpoint 3o	EP3o	H'06	Isochronous-out	60	120	_	command control, audio
Endpoint 4	EP4	H'07	Interrupt-in	16	16	_	SD/MMC
Endpoint 5	EP5	H'08	Bulk-in	32	64	Possible	memory card
Endpoint 6	EP6	H'09	Bulk-out	32	64	Possible	- 0414

- Interrupt requests: generates various interrupt signals necessary for USB transmission/reception
- Clock: Selection of internal system clock/external input (48 MHz) by means of EXCPG
- Power-down mode

Power consumption can be reduced by stopping UDC internal clock when USB cable is disconnected

Automatic transition to/recovery from suspend state

• Power mode: Self-powered, bus-powered

www.DataSheet4U.com

Rev. 1.00, 02/04, page 547 of 804

• Endpoint configuration: An arbitrary endpoint configuration can be set. (Endpoint configuration based on the Bluetooth specification standard is also supported.)

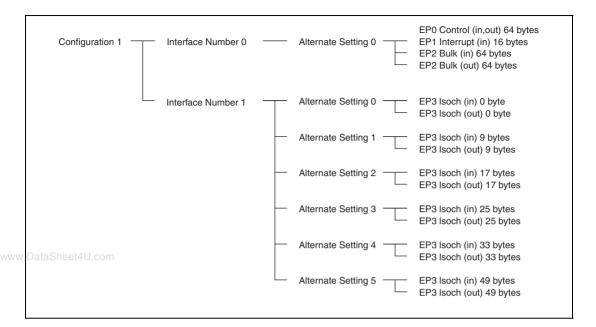

Figure 20.1 shows the block diagram of USBF.

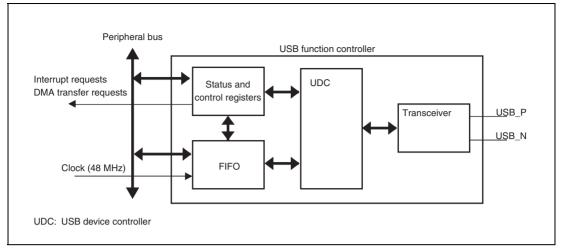

Figure 20.1 Block Diagram of USB Function Controller

# 20.2 Input/Output Pins

Table 20.1 lists the pin configuration of USBF. For further information on pin settings, see section 18, USB Pin Multiplex Controller (USBPM).

**Table 20.1 Pin Configuration** 

Pin Name	I/O	Function
UCLK	Input	External clock pin
		Pin for directly inputting an external clock of 48 MHz
USB_PWR_EN/	Output	Power enable pin/pull-up control pin
USB_PULLUP		Power-supply application enable control for USBH/pull-up control pin for USBF
USB_OVR_CRNT/	Input	Over current pin/VBUS pin
USB_VBUS		Over current detection for USBH/USB-cable connection monitor pin for USBF
USB_P	I/O	P pin
		Port transceiver D + pin
USB_N	I/O	N pin
		Port transceiver D – pin

# 20.3 Register Descriptions

USB has following registers. For the information on the addresses of these registers and the state of the register in each processing condition, see section 27, List of Registers.

- Interrupt flag register 0 (IFR0)
- Interrupt select register 0 (ISR0)
- Interrupt enable register 0 (IER0)
- EP0i data register (EPDR0i)
- EP0o data register (EPDR0o)
- EP0s data register (EPDR0s)
- EP1 data register (EPDR1)
- EP2i data register (EPDR2i)
- EP2o data register (EPDR2o)
- EP3i data register (EPDR3i)
- www.Deta EP3o data register (EPDR3o)
  - EP4 data register (EPDR4)
  - EP5 data register (EPDR5)
  - EP6 data register (EPDR6)
  - EP0o receive data size register (EPSZ0o)
  - EP2o receive data size register (EPSZ2o)
  - EP3o receive data size register (EPSZ3o)
  - EP6 receive data size register (EPSZ6)
  - Trigger register (TRG)
  - Data status register (DASTS)
  - FIFO clear register (FCLR)
  - DMA transfer setting register (DMA)
  - Endpoint stall register (EPSTL)
  - Configuration value register (CVR)
  - Time stamp register (TSR)
  - Control register (CTLR)
  - Endpoint information register (EPIRn0 to EPIRn5)

## 20.3.1 Interrupt Flag Register 0 (IFR0)

IFR0 is an interrupt flag register for EP0i, EP0o, EP1, EP2i, EP2o, EP3i, EP3o, and EP4 to EP6, bus reset, setup command reception, VBUS, SUS/RES, SOF, SETC, and SETI. When each flag is set to 1 and an interrupt is enabled in the corresponding bit of the interrupt enable register 0 (IER0), an interrupt occurs from the INT pin specified by the corresponding bit in the interrupt select register (ISR0). Interrupt requests and interrupt request signals can be specified by ISR0. Clearing is performed by writing 0 to the bit to be cleared. Writing 1 is not valid and nothing is changed.

	Bit	Bit Name	Initial Value	R/W	Description
	31	_	0	R	Reserved
					This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
Dat	39 <sub>heet4</sub>	BRST	0	R/W	Bus reset
					[Setting condition]
					When a bus reset signal is detected on the USB bus.
					[Clearing conditions]

Notes: 1. FIFO full bits of EP2o and EP6 and FIFO empty bits of EP2i and EP5 are status bits indicating the FIFO states, so they cannot be cleared.

2. The USB connection status (bit 28) is a bit indicating the state of the USB\_VBUS pin, so it cannot be cleared. Output of an interrupt is not carried out either.

# 20.3.2 Interrupt Select Register 0 (ISR0)

ISR selects the interrupt request pin to output the IFR0 interrupt. The USB function module has two interrupt request signals (INT0N and INT1N) to output an interrupt request to the interrupt controller (INTC). If the corresponding bit in ISR0 is cleared to 0, an INT0N interrupt request will be issued and an interrupt request is issued from the INT1N pin when set to 1. INT0N and INT1N interrupt request signals correspond to USBFI0 and USBFI1 of the interrupt controller (INTC), respectively.

In the initial value, each of interrupt source of the interrupt flag register is issued from the INTON interrupt request signal.

# 20.3.3 Interrupt Enable Register 0 (IER0)

IER0 enables the interrupt requests of IFR0. When an interrupt flag is set to 1 while the corresponding bit of each interrupt enable bit of IFR0 is set to 1, the INT0N or INT1N pin set in the interrupt select register (ISR0) is asserted low and an interrupt request is issued.

Bit	Bit Name	Initial Value	R/W	Description

# 20.3.4 EP0i Data Register (EPDR0i)

EPDR0i is a 64-byte 8-bit transmit FIFO buffer for endpoint 0. EPDR0i holds one packet of transmit data for control-in. Transmit data is fixed by writing one packet of data and setting EP0iPKTE in TRG. When an ACK handshake is returned from the host after the data has been transmitted, EP0iTS in IFR0 is set. This FIFO buffer can be initialized by means of EP0iCLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for control-in transfer

#### 20.3.5 EP0o Data Register (EPDR0o)

EPDR00 is a 64-byte 8-bit receive FIFO buffer for endpoint 0. EPDR00 holds endpoint 0 receive data other than setup commands. When data is received normally, EP0oTS in IFR0is set, and the number of receive bytes is indicated in the EP0o receive data size register. After the data has been read, setting EP0oRDFN in TRG enables the next packet to be received. This FIFO buffer can be initialized by means of EP0oCLR in the FIFO clear register (FCLR).

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	R	Data register for control-out transfer

## 20.3.6 EP0s Data Register (EPDR0s)

EPDR0s is a data register specifically for endpoint 0 setup command. EPDR0s holds 8-byte command data sent in the setup stage. However, only the command to be processed by a microprocessor (firmware) is received. The command data to be processed automatically by this module is not stored.

When the reception of data in the setup stage starts during read, the previous data is overwritten unconditionally. When the reception of the next command occurs during command read, the command reception starts and data read during command read is invalid.

Note: EPDR0s must be read in 8-byte units. If reading is suspended while it is in progress, data received in the next setup cannot be read successfully.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	R	Data register for storing the setup command at the control-out transfer

# 20.3.7 EP1 Data Register (EPDR1)

EPDR1 is a 16-byte 8-bit transmit FIFO buffer for endpoint 1. EPDR1 holds one packet of transmit data for the interrupt transfer of endpoint 1. Transmit data is fixed by writing one packet of data and setting EP1PKTE in TRG. When an ACK handshake is returned from the host after the data has been transmitted, EP1TS in IFR0 is set. This FIFO buffer can be initialized by means of EP1CLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for endpoint 1 transfer

### 20.3.8 EP2i Data Register (EPDR2i)

EPDR2i is a 128-byte 8-bit transmit FIFO buffer for endpoint 2i. EPDR2i has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When transmit data is written to this FIFO buffer and EP2iPKTE in TRG is set, one packet of transmit data is fixed, and the dual-FIFO buffer is switched over. Transmit data for this FIFO buffer can be transferred by DMA. This FIFO buffer can be initialized by means of EP2iCLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for endpoint 2i transfer

## 20.3.9 EP2o Data Register (EPDR2o)

EPDR20 is a 128-byte 8-bit receive FIFO buffer for endpoint 20. EPDR20 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. The number of receive byte is displayed in the EPSZ20 register. The buffer on read side can be received again by writing EP20RDFN in TRG to 1 after data is read. The receive data of this FIFO buffer can be transferred by DMA. This FIFO buffer can be initialized by means of EP20CLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	R	Data register for endpoint 20 transfer

# 20.3.10 EP3i Data Register (EPDR3i)

EPDR3i is a 128-byte 8-bit transmit FIFO buffer for endpoint 3i. EPDR3i has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When transmit data is written to this FIFO buffer and an SOF packet is received, one packet of transmit data is fixed, and the dual-FIFO buffer is switched over. This FIFO buffer can be initialized by means of EP3iCLR in FCLR.

Note: When an SOF packet cannot be received, an SOF interrupt is generated by an SOF marker function. However, data in a frame which could not receive an SOF is invalid.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for endpoint 3i transfer

#### 20.3.11 EP3o Data Register (EPDR3o)

EPDR30 is a 120-byte 8-bit receive FIFO buffer for endpoint 30. EPDR30 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. The number of receive byte is displayed in the EPSZ30 register. The receive data is fixed when an SOF packet is received. Accordingly, all receive data must be read until the next SOF packet is received. When the next SOF packet is received, the FIFO side is automatically switched over, and the previous data will not be possible to be read. This FIFO buffer can be initialized by means of EP30 CLR in FCLR.

Note: When an SOF packet cannot be received, an SOF interrupt is generated by an SOF marker function. However, data in a frame which could not receive an SOF is invalid.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	R	Data register for endpoint 3o transfer

### 20.3.12 EP4 Data Register (EPDR4)

EPDR4 is a 16-byte 8-bit transmit FIFO buffer for endpoint 4. EPDR4 holds one packet of transmit data for the interrupt transfer of endpoint 4. Transmit data is fixed by writing one packet of data and setting EP4PKTE in TRG. When an ACK handshake is returned from the host after the data has been transmitted, EP4TS in IFR0 is set. This FIFO buffer can be initialized by means of EP4CLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for endpoint 4 transfer

## 20.3.13 EP5 Data Register (EPDR5)

EPDR5 is a 64-byte 8-bit transmit FIFO buffer for endpoint 5. EPDR5 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When transmit data is written to this FIFO buffer and setting EP5PKTE in the trigger register, one packet of transmit data is fixed, and the dual-FIFO buffer is switched over. Data can be transferred to this FIFO buffer by DMA. This FIFO buffer can be initialized by means of EP5CLR in the FCLR register.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Data register for endpoint 5 transfer

### 20.3.14 EP6 Data Register (EPDR6)

EPDR6 is a 64-byte 8-bit receive FIFO buffer for endpoint 6. EPDR6 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. The number of receive byte is displayed in the EPSZ6 receive data size register. The buffer on read side can be received again by writing EP6RDFN in TRG to 1 after data is read. The receive data of this FIFO buffer can be transferred by DMA. This FIFO buffer can be initialized by means of EP6CLR in FCLR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	D7 to D0	Undefined	R	Data register for endpoint 6 transfer

### 20.3.15 EP0o Receive Data Size Register (EPSZ0o)

EPSZ00 is a receive data size resister for endpoint 0o. EPSZ00 indicates the number of bytes received from the host.

/.Da <b>Bit</b> 5heet4 <b>⋅Bit⊳N</b>	ame Initial Value	R/W	Description
7 to 0 —	All 0	R	Number of receive data for endpoint 0o

### 20.3.16 EP2o Receive Data Size Register (EPSZ2o)

EPSZ20 is a receive data size resister for endpoint 20. EPSZ20 indicates the number of bytes received from the host. FIFO of endpoint 20 has a dual-buffer configuration. The size of the received data indicated by this register is the size of the currently selected side (can be read by CPU).

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	_	All 0	R	Number of received bytes for endpoint 2o

# 20.3.17 EP3o Receive Data Size Register (EPSZ3o)

EPSZ30 is a receive data size resister for endpoint 3. EPSZ30 indicates the number of bytes received from the host. FIFO of endpoint 30 has a dual-buffer configuration. The size of the received data indicated by this register is the size of the currently selected side (can be read by CPU).

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	_	All 0	R	Number of received bytes for endpoint 3o

\_

www.DataSheet4U.com

# 20.3.18 EP6 Receive Data Size Register (EPSZ6)

EPSZ6 is a receive data size resister for endpoint 6. EPSZ6 indicates the number of bytes received from the host. FIFO of endpoint 6 has a dual-buffer configuration. The size of the received data indicated by this register is the size of the currently selected side (can be read by CPU).

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	_	All 0	R	Number of received bytes for endpoint 6

## 20.3.19 Trigger Register (TRG)

TRG generates one-shot triggers FIFO for each endpoint of EP0s, EP0i, EP0o, EP1, EP2i, EP2o, EP4, EP5, and EP6. The packet enable trigger for the IN FIFO register and read complete trigger for the OUT FIFO register are triggers to be given. If a bit corresponding to each endpoint is set to 1, a trigger is given. Each bit in this register is automatically cleared to 0 after it is set to 1.

	<b>Bit</b> heet4U	Bit Name	Initial Value	R/W	Description
	15	_	0	_	Reserved
					The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
	14	EP6 RDFN	0	W	EP6 Read Complete
	13	EP5 PKTE	0	W	EP5 Packet Enable
•	12	EP4 PKTE	0	W	EP4 Packet Enable
	11 to 7	_	All 0	_	Reserved
					The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
•	6	EP2o RDFN	0	W	EP2o Read Complete
	5	EP2i PKTE	0	W	EP2i Packet Enable
	4	EP1 PKTE	0	W	EP1 Packet Enable
	3	_	0	_	Reserved
					The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
•	2	EP0s RDFN	1	W	EP0s Read Complete
•	1	EP0o RDFN	0	W	EP0o Read Complete
	0	EP0i PKTE	0	W	EP0i Packet Enable

#### 20.3.20 Data Status Register (DASTS)

DASTS indicates whether the transmit FIFO data register contains valid data. DASTS is set to 1 when data written to the transmit FIFO is enabled by writing PKTE in TRG to 1, and cleared to 0 when all data has been transmitted to the host. In case of a dual-configuration FIFO for endpoints 2i and 5, this bit is cleared to 0 when both sides are empty.

Bit	Bit Name	Initial Value	R/W	Description
7	_	0	R	Reserved
				This bit is always read as 0.
6	EP5DE	0	R	EP5 Data Enable
5	EP4DE	0	R	EP4 Data Enable
4	_	0	R	Reserved
				This bit is always read as 0.
3	EP2iDE	0	R	EP2i Data Enable
D <b>a</b> aSheet	4EPIDE	0	R	EP1 Data Enable
1	_	0	R	Reserved
				This bit is always read as 0.
0	EP0iDE	0	R	EP0i Data Enable

## 20.3.21 FIFO Clear Register (FCLR)

FCLR is a one shot register to clear the FIFO buffers for each endpoint. Writing 1 to a bit clears the data in the corresponding FIFO buffer. Each bit in this register is automatically cleared to 0 after it is set to 1.

In case of the transmit FIFO, by writing data in the FIFO buffer, the data by which PKTE in TRG is not written to 1 and the data enabled by writing 1 can be cleared. In case of the receive FIFO, the unfixed data during reception and the data of which reception has not been completed can be cleared.

Both sides of the dual-configuration FIFO buffers for EP2i, EP2o, EP3i, EP3o EP5, and EP6 can be cleared.

The corresponding interrupt flag is not cleared by this clear instruction. Do not clear a FIFO buffer during transmission.

Bit	Bit Name	Initial Value	R/W	Description
15	_	_	_	Reserved
				The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
14	EP6 CLR	_	W	EP6 Clear
13	EP5 CLR	_	W	EP5 Clear
12	EP4 CLR	_	W	EP4 Clear
11	_	_	_	Reserved
				The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
10	EP3o CLR	_	W	EP3o Clear
9	EP3i CLR	_	W	EP3i Clear
8, 7	_	_	_	Reserved
				The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
at <mark>6</mark> Shee	EP2o CLR	_	W	EP2o Clear
5	EP2i CLR	_	W	EP2i Clear
4	EP1 CLR	_	W	EP1 Clear
3, 2	_	_	_	Reserved
				The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
1	EP0o CLR	_	W	EP0o Clear
0	EP0i CLR	_	W	EP0i Clear

# 20.3.22 DMA Transfer Setting Register (DMA)

DMA is set when the dual address transfer of the DMAC is used to the data register for endpoints EP2i, EP2o, EP5, and EP6 to which transfer is possible by DMA.

Bit	Bit Name	Initial Value	R/W	Description
7	EP6 DMAE	0	R/W	EP6DMA Enable
				Enables DMA transfer for EP6.
6	EP6 DMAS	0	R/W	EP6DMA Request Select
				Selects DMA transfer request output for EP6.
5	EP5 DMAE	0	R/W	EP5DMA Enable
				Enables DMA transfer for EP5.

Bit	Bit Name	Initial Value	R/W	Description
4	EP5 DMAS	0	R/W	EP5DMA Request Select
				Selects DMA transfer request output for EP5.
3	EP2o DMAE	0	R/W	EP2oDMA Enable
				Enables DMA transfer for EP2o.
2	EP2o DMAS	0	R/W	EP2oDMA Request Select
				Selects DMA transfer request output for EP2o.
1	EP2i DMAE	0	R/W	EP2iDMA Enable
				Enables DMA transfer for EP2i.
0	EP2i DMAS	0	R/W	EP2iDMA Request Select
				Selects DMA transfer request output for EP2i.

### **20.3.23** Endpoint Stall Register (EPSTL)

www.DEPSTE stalls each endpoint. The endpoint in which the stall bit is set to 1 returns a stall handshake to the host from the next transfer when 1 is written to. The stall bit for endpoint 0 is cleared automatically on reception of 8 byte command data for which decoding is performed by the function and the EP0 STL bit is cleared. When the SETUPTS bit in IFR0 is set to 1, a write of the EP0 STL bit to 1 is ignored. For detailed operation, see section 20.6, Stall Operations.

		Initial		
Bit	Bit Name	Value	R/W	Description
15 to 1	1 —	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
10	EP6 STL	0	R/W	EP6 Stall
				Sets EP6 stall
9	EP5 STL	0	R/W	EP5 Stall
				Sets EP5 stall
8	EP4 STL	0	R/W	EP4 Stall
				Sets EP4 stall
7	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
6	EP3o STL	0	R/W	EP3o Stall
				Sets EP3o stall
	· ·	·	· · · · · · · · · · · · · · · · · · ·	<u> </u>

		Initial			
Bit	Bit Name	Value	R/W	Description	
5	EP3i STL	0	R/W	EP3i Stall	
				Sets EP3i stall	
4	_	0	R	Reserved	
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.	
3	EP2o STL	0	R/W	EP2o Stall	
				Sets EP2o stall	
2	EP2i STL	0	R/W	EP2i Stall

1	EP1 STL	0	R/W	EP1 Stall	
				Sets EP1 stall	
0	EP0 STL	0	R/W	EP0 Stall	
nta Shoo	st411.com			Sets EP0 stall	

# 20.3.24 Configuration Value Register (CVR)

CVR is a register to store the Configuration/Interface/Alternate value to be set when the Set Configuration/Set Interface command is normally received from the host.

Bit	Bit Name	Initial Value	R/W	Description	
7	CNFV	0	R	Configuration Value	
			The configuration setting value is stored when the Set Configuration command has been received.		
				CNFV is updated when SETC in the interrupt flag register, IFR0, is set to 1.	
6	INTV3	0	R	Interface Value	
5	INTV2	0	R	The interface setting value is stored when the Set Interface	
4	INTV1	0	R	command has been received.	
3	INTV0	0	R	INTV is updated when SETI in the interrupt flag register, IFR0, is set to 1.	
2	ALTV2	0	R	Alternate Value	
1	ALTV1	0	R	The alternate setting value is stored when the Set interface	
0	ALTV0	0	R	command has been received.	
				ALTV is updated when SETI in the interrupt flag register, IFR0, is set to 1.	

# 20.3.25 Time Stamp Register (TSR)

TSR is a register to store the current time stamp value. The time stamp is updated when the SOF bit in IFR0 is set to 1. The value of the time stamp when the SOF marker function is enabled and the SOF packet is broken remains as previous one.

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	l —	All 0	R	Reserved.
				These bits are always read as 0.
10	D10	0	R	Time stamp data
9	D9	0	R	
8	D8	0	R	
7	D7	0	R	
6	D6	0	R	
5	D5	0	R	
.DataSheet	4 <b>D4</b> 4 <b>U</b> .com	0	R	
3	D3	0	R	
2	D2	0	R	
1	D1	0	R	
0	D0	0	R	

# 20.3.26 Control Register (CLTR)

CLTR is a register to make various settings of the USBF.

When the isochronous transfer is used, the SOF marker function must be enabled.

Bit	Bit name	Initial value	R/W	Description
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
5	PULLUPE	0	R/W	Pull-up Enable
				Controls the output value of the USB_PULLUP pin.

Bit	Bit name	Initial value	R/W	Description
4	RWUPS	0	R	Remote Wakeup Status
				Status bit to indicate that the remote wakeup from the host is enabled/disabled. Indicates 0 when the remote wakeup is disabled with Device Remote Wakeup by the Set Feature/Clear Feature request and indicates 1 when it is enabled.
3	RSME	0	R/W	Resume Enable
				Bit to clear the suspend state (performs the remote wakeup)
				When this bit is written to 1, a resume register is set.
				When this bit will be used, be sure to hold to 1 for one clock or more at 12 MHz in minimum and then clear to 0 again.
2	PWMD	0	R/W	Power Mode Select
				0: USBF is operated in self-powered mode
				1: USBF is operated in bus-powered mode
1	ASCE	0	R/W	Automatic Stall Clear Enable
				When this bit is set to 1, the stall handshake is returned to the host and the stall setting bit (EPSTLR/EPxSTL) of the returned endpoint is automatically cleared. Control in a unit of endpoint is disabled as this bit is common for all endpoints. When this bit is set to 0, be sure to clear the stall setting bit of each endpoint by using software.
				Enable this bit before setting EPSTL to 1.
0	SOFME	0	R/W	SOF Marker Function Enable
				Controls SOF marker function.
				When this bit is set to 1, the SOF interrupt flag is set to 1 every 1 msec even if an SOF packet is broken. Before setting this bit to 1, check if the SOF interrupt flag of IFR0 register is detected correctly. If a suspension is detected, this bit must be cleared to 0. Before setting this bit to 1 again, check the SOF detection.

## 20.3.27 Endpoint Information Register (EPIRn0 to EPIRn5)

EPIR is a register to set the configuration information for each endpoint. 6 bytes of the information are required for one endpoint. Write the data in order from endpoint 0. Do not write more than 6 (bytes)  $\times$  19 (endpoints) = 114 bytes. Write this information once at power-on reset. Do not write it again afterwards.

Write data of one endpoint is described below. EPIR writes data in the same address in order. Therefore though there is only one EPIR register, write data for registration number n (n is from 0 to 18) is listed as EPIRn0 to EPIRn5 (EPIR [registration number] [write order]) for the purpose of explaining. Write data in order from EPIR00.

#### EPIRn0

	Bit	Bit Name	Initial value	R/W	Description	
	7 to 4	D7 to D4	Undefined	W	Endpoint Number	
			Settable range: B'0000 to B'0110			
					Note: B'0111 to B'1111 = Setting prohibited	
3 to 0 D3 to D0 Undefined W Configuration number to which endpoint be		Configuration number to which endpoint belongs				
			Settable range: B'0000 to B'0001			
				Note: B'0010 to B'1111 = Setting prohibited		

#### EPIRn1

Bit	Bit Name	Initial value	R/W	Description
7 to 4	D7 to D4	Undefined	W	Interface number to which endpoint belongs
				Settable range: B'0000 to B'0010
				Note: B'0011 to B'1111 = Setting prohibited
3 to 0	D3 to D0	Undefined	W	Alternate number to which endpoint belongs
				Settable range: Differs based on the interface number (D7 to D4)
				D7 to D4 = B'0000: D3 to D0 = B'0000
				D7 to D4 = B'0001: D3 to D0 = B'0000 to B'0101
				D7 to D4 = B'0010: D3 to D0 = B'0000
				Note: Other than above = Setting prohibited

# • EPIRn2

Bit	Bit Name	Initial value	R/W	Description	
7, 6	D7, D6	Undefined	W	Reserved	
			The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.		
5, 4	D5, D4	Undefined	W	Transfer Method of Endpoint	
				[Settable range]	
				B'00: Control	
				B'01: Isochronous	
				B'10: Bulk	
				B'11: Interrupt	
3	D3	Undefined	W	Transfer Direction of Endpoint	
				[Settable range]	
				B'0: Out	
				B'1: In	
2 to 0	D2 to D0	Undefined	W	Reserved	
				The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.	

# • EPIRn3

Bit	Bit Name	Initial value	R/W	Description	
7 to 1	D7 to D1	Undefined	W	Maximum Packet Size of Endpoint	
				Settable range: B'0000000 to B'1000000	
				Note: B'1000001 to B'1111111 = Setting prohibited	
0	D0	Undefined	W	Reserved	
				The write value should always be 0. If 1 is written in this bit, correct operation cannot be guaranteed.	

# • EPIRn4

Bit	Bit Name	Initial value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Reserved
				The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

#### EPIRn5

Bit	Bit Name	Initial value	R/W	Description
7 to 0	D7 to D0	Undefined	W	Endpoint FIFO Number
			Settable range: H'00 to H'03, H'05 to H'09	
				Note: H'04, H'0A to H'FF = Setting prohibited

An endpoint number specified by the EPIRn0 register is an endpoint number used by the USB host. The endpoint FIFO number specified by the EPIRn5 register corresponds to the FIFO number which is attached to each endpoint physically supported by this USB function module. For details on correspondence between the endpoint functions and FIFO numbers in this USB function module, refer to section 20.1, Features. Note that the setting values for EPIRn0 to EPIRn5 are limited as described below

- Since each endpoint FIFO is optimized by a dedicated hardware corresponding to each transfer method, transfer direction, and maximum packet size, set the endpoint FIFO with a many Datas transfer method, transfer direction, and maximum packet size shown in the table 20.2. Example: Endpoint FIFO number 1 cannot be set as other than interrupt transfer and maximum packet size (16 bytes). Although endpoint FIFO number 5 cannot be set as other than isochronous transfer and IN, maximum packet size can be set in the range of 0 to 64 bytes.
  - 2. Endpoint number 0 and endpoint FIFO number 0 must correspond.
  - 3. The maximum packet size of endpoint FIFO number 0 can be set to 64 bytes only.
  - 4. The setting value of endpoint FIFO number 0 can be set to the maximum packet size only and the rest data is all 0.
  - 5. The maximum packet size of endpoint FIFO numbers 1 and 7 can be set to 16 only.
  - The maximum packet size of endpoint FIFO numbers 2 and 3 can be set to 64 only. 6.
  - 7. The maximum packet size of endpoint FIFO numbers 8 and 9 can be set to 32 only.
  - 8. The maximum packet size of endpoint FIFO number 5 can be set in the range of 0 to 64.
  - The maximum packet size of endpoint FIFO number 6 can be set in the range of 0 to 60.
  - 10. When the isochronous transfer is set, Alternate can be used in the range of 0 to 5 for the same endpoint. Be sure to allocate the Alternate to the same endpoint FIFO number.
  - 11. Endpoint information can be set up to 19 in maximum.
  - 12. Endpoint information of 19 pieces must be written.
  - 13. All information of endpoints which are not used must be written as 0.

A list of restrictions of settable transfer method, transfer direction, and maximum packet size is described in table 20.2.

RENESAS

www.DataSheet4U.com

**Table 20.2 Restrictions of Settable Values** 

Endpoint FIFO No.	Maximum Packet Size	Transfer Method	Transfer Direction
0	64 bytes	Control	_
1	16 bytes	Interrupt	IN
2	64 bytes	Bulk	IN
3	64 bytes	Bulk	OUT
5	0 to 64 bytes	Isochronous	IN
6	0 to 60 bytes	Isochronous	OUT
7	16 bytes	Interrupt	IN
8	32 bytes	Bulk	IN
9	32 bytes	Bulk	OUT

Examples of settings are shown below.

**Example of Setting 1:** This is an example which is recommended by HCI USB TRANSPORT LAYER. Data for definition numbers 16 to 18 must be all 0s.

**Table 20.3** Example of Endpoint Configuration (1)

EP No.	Conf.	Int.	Alt.	Transfer Method	Transfer Direction	Maximum Packet Size	EP FIFO No.

# 20.4 Operation

#### 20.4.1 Cable Connection

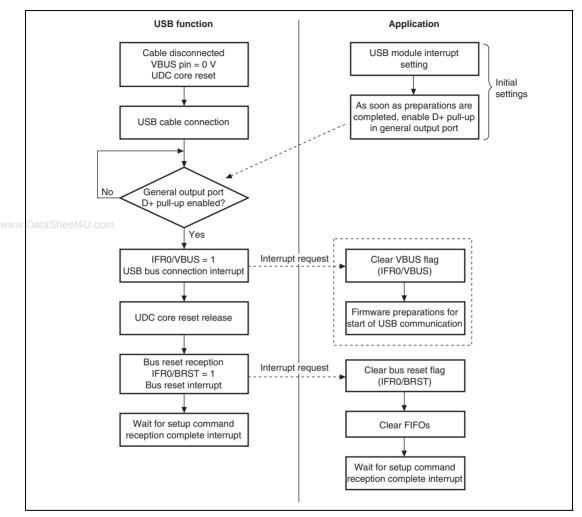

Figure 20.4 Cable Connection Operation

The above flowchart shows the operation in the case of in section 20.7, Example of External Circuitry for USB Function Controller.

In applications that do not require USB cable connection to be detected, processing by the USB bus connection interrupt is not necessary. Preparations should be made with the bus reset interrupt.

For details, see section 20.7, Example of External Circuitry for USB Function Controller.

www.DataSheet4U.com

#### 20.4.2 Cable Disconnection

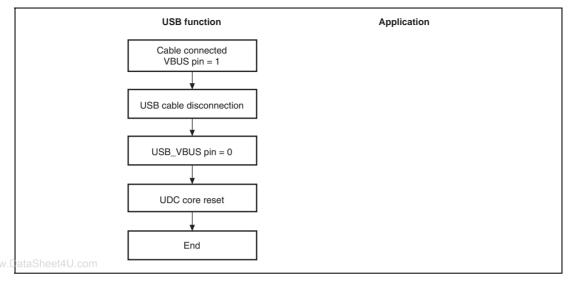

Figure 20.5 Cable Disconnection Operation

The above flowchart shows the operation in section 20.7, Example of External Circuitry for USB Function Controller.

For details, see section 20.7, Example of External Circuitry for USB Function Controller.

#### 20.4.3 Control Transfer

Control transfer consists of three stages: setup, data (not always included), and status (figure 20.6). The data stage comprises a number of bus transactions. Operation flowcharts for each stage are shown below.

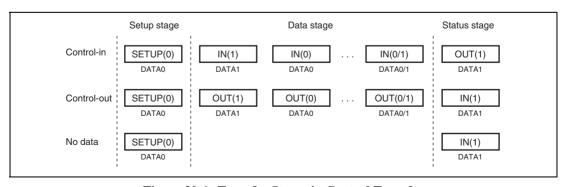

Figure 20.6 Transfer Stages in Control Transfer

#### **Setup Stage:**

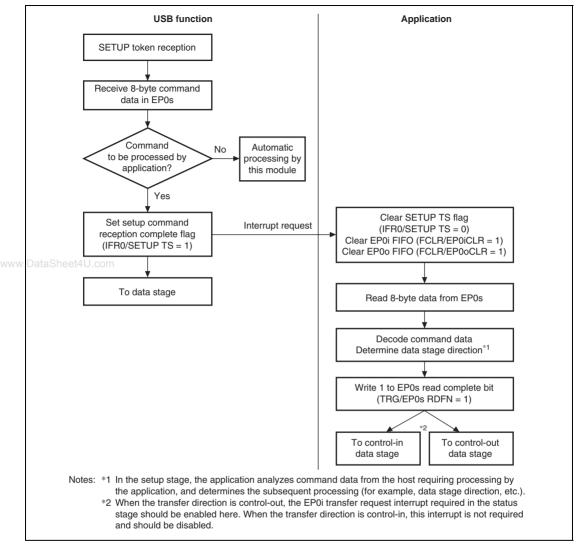

Figure 20.7 Setup Stage Operation

## **Data Stage (Control-In):**

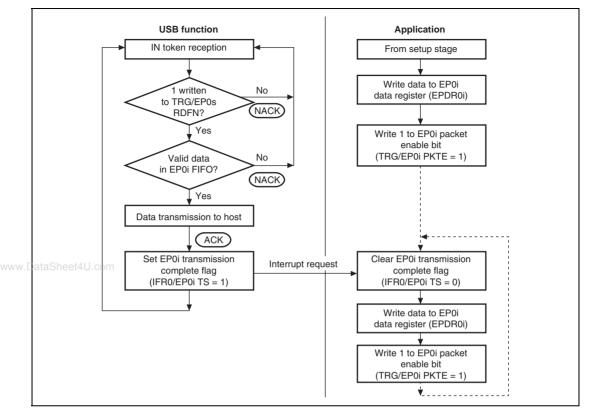

Figure 20.8 Data Stage (Control-In) Operation

The application first analyzes command data from the host in the setup stage, and determines the subsequent data stage direction. If the result of command data analysis is that the data stage is intransfer, one packet of data to be sent to the host is written to the FIFO. If there is more data to be sent, this data is written to the FIFO after the data written first has been sent to the host  $(IFRO/EP0i\ TS = 1)$ .

The end of the data stage is identified when the host transmits an OUT token and the status stage is entered.

Note: If the size of the data transmitted by the function is smaller than the data size requested by the host, the function indicates the end of the data stage by returning to the host a packet shorter than the maximum packet size. If the size of the data transmitted by the function is an integral multiple of the maximum packet size, the function indicates the end of the data stage by transmitting a zero-length packet.

## **Data Stage (Control-Out):**

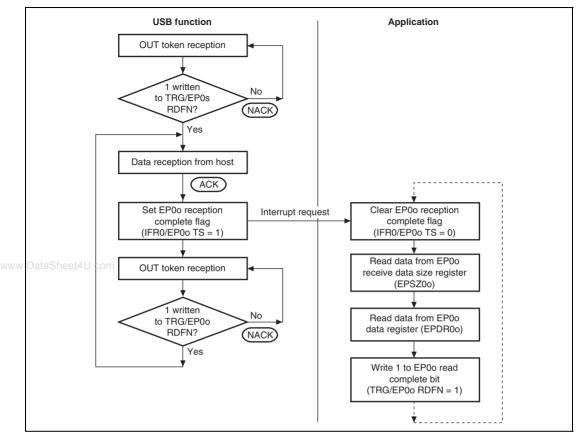

Figure 20.9 Data Stage (Control-Out) Operation

The application first analyzes command data from the host in the setup stage, and determines the subsequent data stage direction. If the result of command data analysis is that the data stage is outtransfer, the application waits for data from the host, and after data is received (IFR0/EP0o TS = 1), reads data from the FIFO. Next, the application writes 1 to the EP0o read complete bit, empties the receive FIFO, and waits for reception of the next data.

The end of the data stage is identified when the host transmits an IN token and the status stage is entered.

## Status Stage (Control-In):

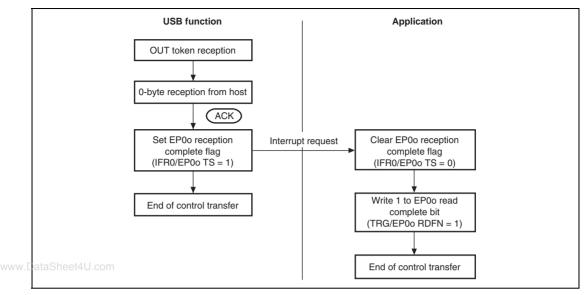

Figure 20.10 Status Stage (Control-In) Operation

The control-in status stage starts with an OUT token from the host. The application receives 0-byte data from the host, and ends control transfer.

## **Status Stage (Control-Out):**

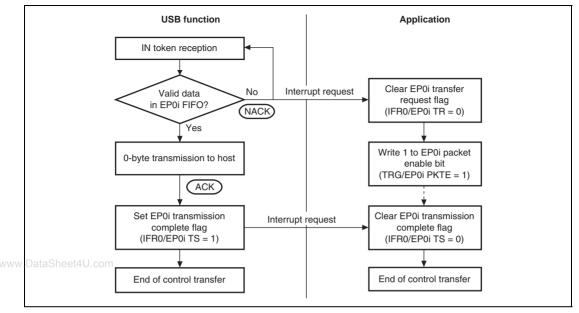

Figure 20.11 Status Stage (Control-Out) Operation

The control-out status stage starts with an IN token from the host. When an IN-token is received at the start of the status stage, there is not yet any data in the EP0i FIFO, and so an EP0i transfer request interrupt is generated. The application recognizes from this interrupt that the status stage has started. Next, in order to transmit 0-byte data to the host, 1 is written to the EP0i packet enable bit but no data is written to the EP0i FIFO. As a result, the next IN token causes 0-byte data to be transmitted to the host, and control transfer ends.

After the application has finished all processing relating to the data stage, 1 should be written to the EP0i packet enable bit.

## 20.4.4 EP1, 4 Interrupt-In Transfer

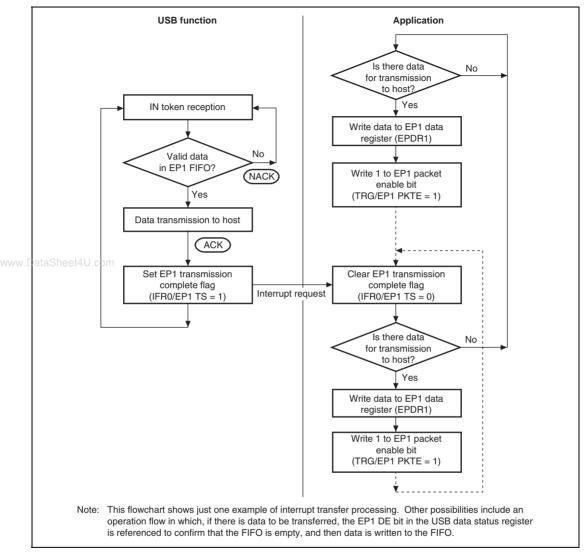

Figure 20.12 EP1 Interrupt-In Transfer Operation

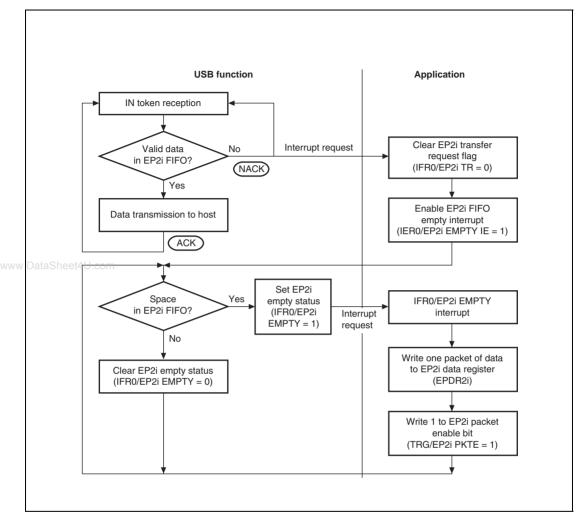

Figure 20.13 EP2 Bulk-In Transfer Operation

EP2i has two 64-byte FIFOs, but the user can perform data transmission and transmit data writes without being aware of this dual-FIFO configuration. However, one data write is performed for one FIFO. For example, even if both FIFOs are empty, it is not possible to perform EP2i/PKTE at one time after consecutively writing 128 bytes of data. EP2i/PKTE must be performed for each 64-byte write.

When performing bulk-in transfer, as there is no valid data in the FIFOs on reception of the first IN token, an IFR0/EP2i TR interrupt is requested. With this interrupt, 1 is written to the IER0/EP2i EMPTY IE bit, and the EP2i FIFO empty interrupt is enabled. At first, both EP2i FIFOs are empty, and so an EP2i FIFO empty interrupt is generated immediate. DataSheet4U.com

Rev. 1.00, 02/04, page 594 of 804

The data to be transmitted is written to the data register using this interrupt. After the first transmit data write for one FIFO, the other FIFO is empty, and so the next transmit data can be written to the other FIFO immediately. When both FIFOs are full, IFR0/EP2i EMPTY is cleared to 0. If at least one FIFO is empty, IFR0/EP2i EMPTY is set to 1. When ACK is returned from the host after data transmission is completed, the FIFO used in the data transmission becomes empty. If the other FIFO contains valid transmit data at this time, transmission can be continued.

When transmission of all data has been completed, write 0 to IER0/EP2i EMPTY IE and disable interrupt requests.

## 20.4.6 EP2o, 6 Bulk-Out Transfer (Dual FIFOs)

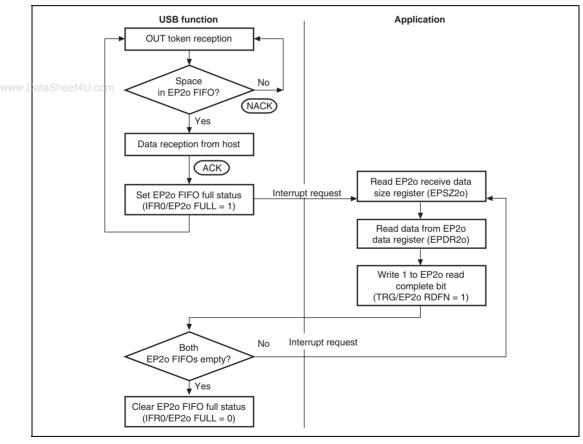

Figure 20.14 EP2o Bulk-Out Transfer Operation

EP2o has two 64-byte FIFOs, but the user can perform data reception and receive data reads without being aware of this dual-FIFO configuration.

When one FIFO is full after reception is completed, the IFR0/EP20 FULL bit is set. After the first receive operation into one of the FIFOs when both FIFOs are empty, the other FIFO is empty, and so the next packet can be received immediately. When both FIFOs are full, NACK is returned to the host automatically. When reading of the receive data is completed following data reception, 1 is written to the TRG/EP20 RDFN bit. This operation empties the FIFO that has just been read, and makes it ready to receive the next packet.

www.DataSheet4LLcom

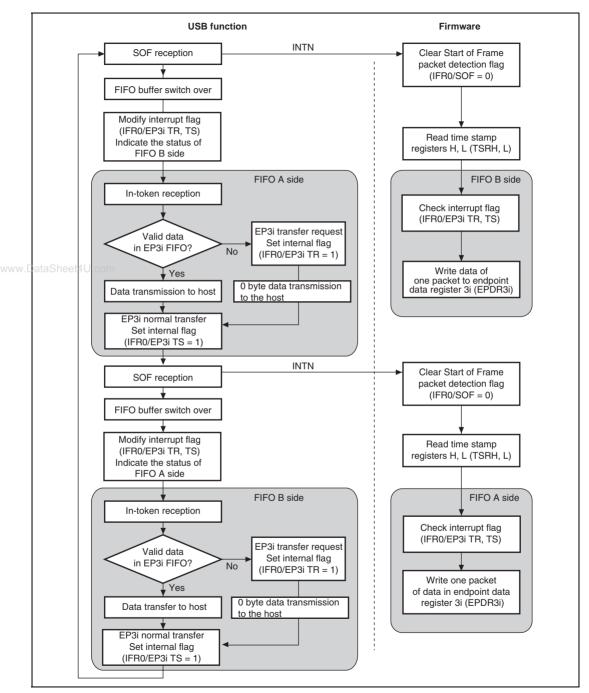

Figure 20.15 Operation of Isochronous-In Transfer

www.DataSheet4U.com

Rev. 1.00, 02/04, page 597 of 804

EP3i has two 64-byte FIFOs in maximum, but the user can perform data transmission and write transmit data without being aware of this dual-FIFO configuration. (In figure 20.15, FIFO sides A and B are used for description.)

In isochronous transfer, transfer is occurred only once per one frame (1 ms). So, when SOF is received, the FIFO buffer is switched automatically with hardware (the FIFO buffer is switched automatically at a cycle of 1 ms by hardware if the SOF marker function is enabled even in the case that SOF cannot be received by error).

FIFO buffers are switched over by the SOF reception. Therefore, the FIFO buffer in which the USB function module transmits the data to the host and the FIFO buffer in which the firmware writes the transmit data have different buffers, and a read and write of FIFO buffer are not competed. Accordingly, the data written by the firmware is the data to be transmitted in one frame after. The buffers of FIFOs are switched over automatically by the SOF reception, so a write of data must be completed within the frame.

The USB function module transmits data to the host and set the TS internal flag to 1 when data to be transmitted to the host exists in FIFO after an in-token is received. If there is no data in the FIFO buffer, set the TR internal flag to 1 and transmit 0-byte data to the host. The internal flag (TR, TS) information is automatically modified as IFRO flag information (TR, TS) that can be read by the SOF reception from the firmware.

In firmware, first, the processing routine of the isochronous transfer is called by SOF interrupt to check the time stamp. Then one packet data is written to FIFO. This written data is transmitted to the host in the next frame. Whether the previous frame has been transmitted normally or not can be determined by reading the IFRO flag information (TR, TS).

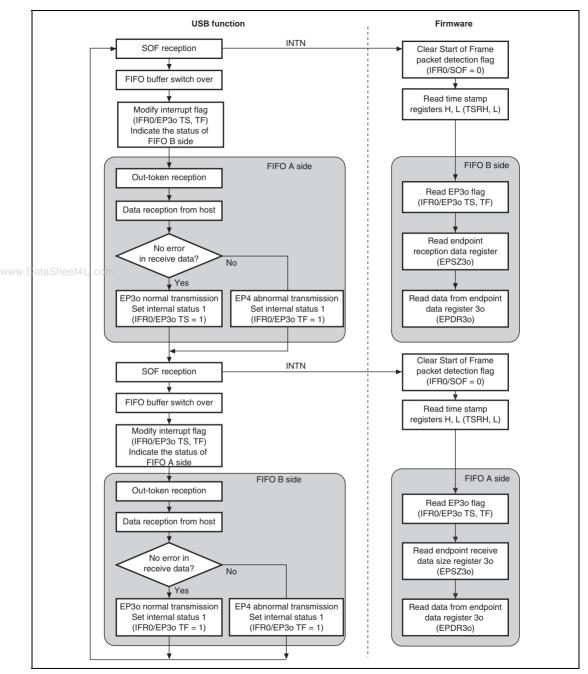

Figure 20.16 Operation of EP3o Isochronous-Out Transfer

EP3o has two 60-byte FIFOs in maximum, but the user can perform data transmission and read transmit data without being aware of this dual-FIFO configuration. (In figure 20.16, FIFO sides A and B are used for description.)

In isochronous transfer, transfer is occurred only once per one frame (1 ms). So, when SOF is received the FIFO buffer is switched automatically with hardware (the FIFO buffer is switched automatically at a cycle of 1 ms by hardware if the SOF marker function is enabled even in the case that SOF cannot be received by error).

FIFO buffers are switched over by the SOF reception. Therefore, the FIFO buffer in which the USB function module receives the data from the host and the FIFO buffer in which the firmware reads the receive data have different buffers, and a read and write of FIFO buffer are not competed. Accordingly, the data written by the firmware is the data received in one frame before. The buffers of FIFOs are switched over automatically by the SOF reception, so a read of data must be completed within the frame.

The USB function module receives data from the host after an out-token is received. If there is an error in the data, set the TF internal flag to 1. If there is no error in the data, set the TS internal flag to 1. The internal flag (TF, TS) information is automatically modified as IFR0 flag information (TF, TS) that can be read by the SOF reception from the firmware.

In firmware, first, the processing routine of the isochronous transfer is called by SOF interrupt to check the time stamp. Then data is read from the FIFO buffer. IFR0 flag information (TS, TF) is read and decided if the data has an error. The IFR0 flag information at this time represents the status of the currently readable FIFO buffer.

# 20.5 Processing of USB Standard Commands and Class/Vendor Commands

## 20.5.1 Processing of Commands Transmitted by Control Transfer

A command transmitted from the host by control transfer may require decoding and execution of command processing on the application side. Whether command decoding is required on the application side is indicated in table 20.7 below.

Table 20.7 Command Decoding on Application Side

Decoding not Necessary on Application Side	Decoding Necessary on Application Side
Clear Feature	Get Descriptor
Get Configuration	Class/Vendor command
Get Interface	Synch Frame
Get Status	Set Descriptor
Set Address	
Set Configuration	
Set Feature	
Set Interface	

If decoding is not necessary on the application side, command decoding, data stage, and status stage processing are performed automatically. No processing is necessary by the user. An interrupt is not generated in this case.

If decoding is necessary on the application side, this module stores the command in the EP0s FIFO. After normal reception is completed, the IFR0/SETUP TS flag is set and an interrupt request is generated. In the interrupt routine, 8 bytes of data must be read from the EP0s data register (EPDR0s) and decoded by firmware. The necessary data stage and status stage processing should then be carried out according to the result of the decoding operation.

# 20.6 Stall Operations

#### **20.6.1** Overview

This section describes stall operations in this module. There are two cases in which the USB function module stall function is used:

- When the application forcibly stalls an endpoint for some reason
- When a stall is performed automatically within the USB function module due to a USB specification violation

The USB function module has internal status bits that hold the status (stall or non-stall) of each endpoint. When a transaction is sent from the host, the module references these internal status bits and determines whether to return a stall to the host. These bits cannot be cleared by the application; they must be cleared with a Clear Feature command from the host.

However, the internal status bit to EP0 is automatically cleared only when the setup command is received.

## 20.6.2 Forcible Stall by Application

The application uses the EPSTL register to issue a stall request for the USB function module. When the application wishes to stall a specific endpoint, it sets the corresponding bit in EPSTL (1-1 in figure 20.17). The internal status bits are not changed at this time. When a transaction is sent from the host for the endpoint for which the EPSTL bit was set, the USB function module references the internal status bit, and if this is not set, references the corresponding bit in EPSTL (1-2 in figure 20.17). If the corresponding bit in EPSTL is set, the USB function module sets the internal status bit and returns a stall handshake to the host (1-3 in figure 20.17). If the corresponding bit in EPSTL is not set, the internal status bit is not changed and the transaction is accepted.

Once an internal status bit is set, it remains set until cleared by a Clear Feature command from the host, without regard to the EPSTL register. Even after a bit is cleared by the Clear Feature command (3-1 in figure 20.17), the USB function module continues to return a stall handshake while the bit in EPSTL is set, since the internal status bit is set each time a transaction is executed for the corresponding endpoint (1-2 in figure 20.17). To clear a stall, therefore, it is necessary for the corresponding bit in EPSTL to be cleared by the application, and also for the internal status bit to be cleared with a Clear Feature command (2-1, 2-2, and 2-3 in figure 20.17).

www.DataSheet4U.com

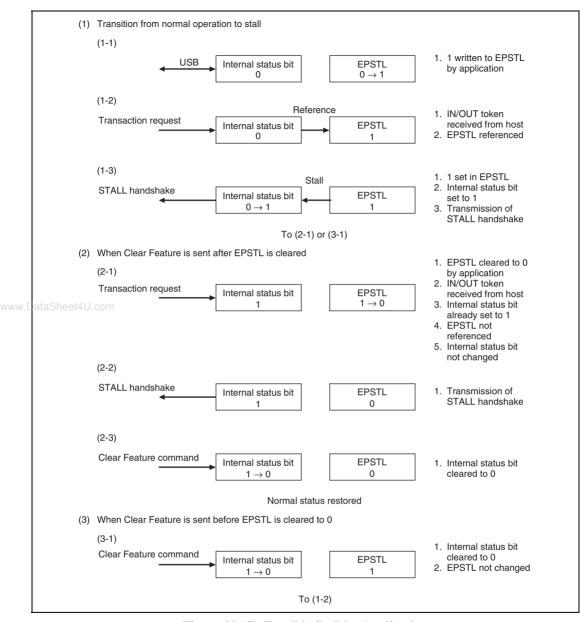

Figure 20.17 Forcible Stall by Application

## 20.6.3 Automatic Stall by USB Function Module

When a stall setting is made with the Set Feature command, or in the event of a USB specification violation, the USB function module automatically sets the internal status bit for the relevant endpoint without regard to the EPSTL register, and returns a stall handshake (1-1 in figure 20.18).

Once an internal status bit is set, it remains set until cleared by a Clear Feature command from the host, without regard to the EPSTL register. After a bit is cleared by the Clear Feature command, EPSTL is referenced (3-1 in figure 20.18). The USB function module continues to return a stall handshake while the internal status bit is set, since the internal status bit is set even if a transaction is executed for the corresponding endpoint (2-1 and 2-2 in figure 20.18). To clear a stall, therefore, the internal status bit must be cleared with a Clear Feature command (3-1 in figure 20.18). If set by the application, EPSTL should also be cleared (2-1 in figure 20.18).

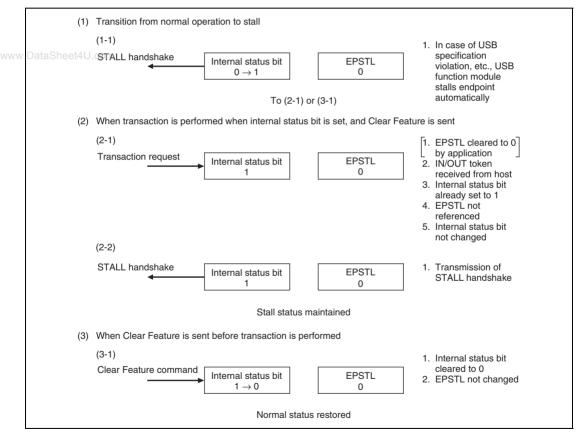

Figure 20.18 Automatic Stall by USB Function Module

# 20.7 Example of External Circuitry for USB Function Controller

**D+ Pull-Up Control:** In a system where it is wished to disable USB host/hub connection notification (D+ pull-up) (during high-priority processing or initialization processing, for example), D+ pull-up should be controlled using a general output port. However, if a USB cable is already connected to the host/hub and D+ pull-up is prohibited, D+ and D- will both go low (both of D+ and D- pulled down on the host/hub side) and the USB function controller will mistakenly identify this as reception of a USB bus reset from the host. Therefore, the D+ pull-up control signal and USB\_VBUS pin input signal should be controlled using an UPLUP output port and the USB cable VBUS (AND circuit) as shown in the circuit example below (The UDC core in this LSI maintains the powered state when the USB\_VBUS pin is low, regardless of the D+/D- state.)

**Detection of USB Cable Connection/Disconnection:** As USB states, etc., are managed by hardware in this module, a VBUS signal that recognizes connection/disconnection is necessary. The power supply signal (VBUS) in the USB cable is used for this purpose. However, if the cable is connected to the USB host/hub when the function (system installed in this LSI) power is off, a voltage (5 V) will be applied from the USB host/hub. Therefore, an IC (such as an HD74LV1G08A or 2G08A) that allows voltage application when the system power is off should be connected externally.

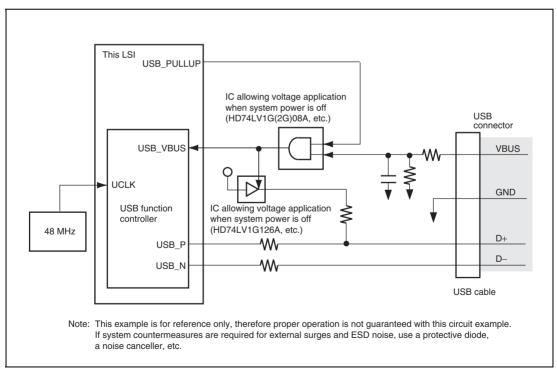

Figure 20.19 Example of USB Function Module External Circuitry

## 20.8 Usage Notes

#### 20.8.1 Setup Data Reception

The following points should be noted on EPDR0s in which reception of 8-byte setup data is performed.

- Since the setup command must be received in the USB, writing from the USB bus side is prior
  to reading from the CPU side. While the CPU reads data after completion of reception and
  reception of the next setup command is started, reading from the CPU side is forcibly invalid
  in order to give priority to writing. Therefore a value to be read after starting reception is
  undefined.
- 2. EPDR0s must be read in 8-byte units. If reading is suspended while it is in progress, data received in the next setup cannot be read successfully.

#### 20.8.2 FIFO Clear

When the USB cable is disconnected during communication, data which is receiving or transmitting may remain in the FIFO. Therefore the FIFO must be cleared immediately after connecting the USB cable again.

Note that the FIFO in which data is receiving from the host or transmitting to the host must not be cleared.

## 20.8.3 Overreading/Overwriting of Data Register

The following points should be noted when the data register of the USB function controller is read from or written to.

Receive Data Register: The receive data register must not read data which is more than valid receive data bytes. That is, data which is more than bytes indicated in the receive data size register must not be read. In case of the receive data register which has the dual FIFO buffer, the maximum number of data which can be read in a single time is maximum packet size. Write 1 to TRG/RDFN after data in the current valid buffer is read. This writing switches the FIFO buffer. Then, the new number of bytes is reflected in the receive data size and the next data can be read.

**Transmit Data Register:** The transmit data register must not write data which is more than maximum packet size. In case of the transmit data register which has the dual FIFO buffer, the maximum number of data which can be written in a single time is maximum packet size. Write 1 to TRG/PKTE after data is written. This writing switches the FIFO buffer. Then, the next data can be written to another buffer. Therefore data must not be written in both buffers in a single time.

www.DataSheet4U.com

#### **20.8.4** Assigning EP0 Interrupt Sources

The EP0 interrupt sources assigned to IFR0 (bits 0, 1, 2, and 29) must be assigned to the same interrupt pins by ISR0. The other interrupt sources have no restrictions.

#### 20.8.5 FIFO Clear when DMA Transfer is Set

When the DMA transfer is enabled in endpoints 20 and 6, the data register cannot be cleared. Cancel the DMA transfer before clearing the data register.

## **20.8.6** Note on Using TR Interrupt

The bulk-in transfer has a transfer request interrupt (TR interrupt). The following points should be noted when using a TR interrupt.

When the IN token is sent from the USB host and there is no data in the corresponding EP FIFO, the TR interrupt flag is set. However, the TR interrupt is generated continuously at the timing as shown in figure 20.20. In this case, note that erroneous operation should not occur.

Note: When the IN token is received and there is no data in the corresponding EP FIFO, an NACK is determined. However, the TR interrupt flag is set after an NACK handshake is transmitted. Therefore when the next IN token is received before TRG/PKTE is written, the TR interrupt flag is set again.

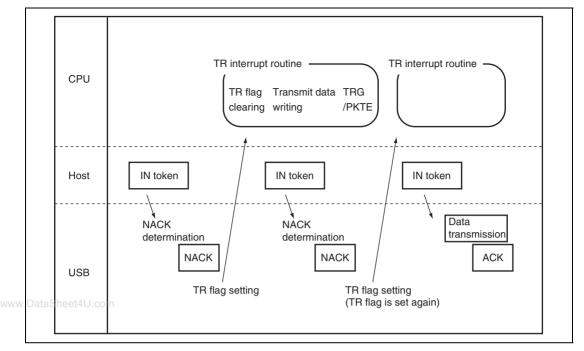

Figure 20.20 Set Timing of TR Interrupt Flag

#### 20.8.7 Note on Clearing and Transition to Software Standby Mode

Figure 20.21 shows an example flow of clearing and transition to software standby mode.

When accessing the USBF again after software standby mode has been cleared, wait for operation stabilization time of the USB clock (48 MHz).

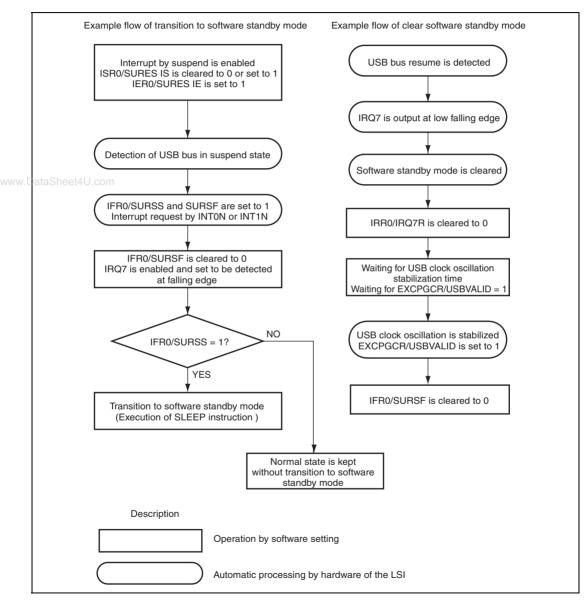

Figure 20.21 Example Flow of Clearing and Transition to Software Standby Mode

## 20.8.8 Main Clock Usage when Using Bus Password Function

When the main clock of this LSI (usually input from EXTAL) is input using the RF chip for the bluetooth as is the clock for the bluetooth interface (usually input from RDI\_REFCLK\_IN), clock cannot be provided again on the recovery from the suspend state. Therefore, when using the buspowered function, a clock in active state should be used as the main clock. To hold down the power consumption in suspend state, the crystal oscillator should be connected to the EXTAL and XTAL pins, in order to provide main clock to the CPU.

## 20.8.9 Peripheral clock for USB

When using USB Function Controller, the frequency of the peripheral clock ( $P\phi$ ) should be 12MHz or larger. With the clock frequency less than 12MHz, the USB Function Controller does not operate normally. Refer to section 11, Clock Pulse Generator (CPG) for a detailed setting of the clock.

www.DataSheet4I.Lcon

# Section 21 Bluetooth Interface (BT)

This LSI incorporates a Bluetooth interface (BT) as hardware for the baseband processing for the Bluetooth. This Bluetooth interface conforms to version 1.1 of the Bluetooth Specification, is configured by combination of hardware and firmware, and provides a lower protocol stack function to the host controller interface (HCI) layer. With this function, Bluetooth logo certification is acquired for a baseband layer (BB) and link management protocol layer (LMP).

To configure the upper protocol stack, HCI commands which are defined by version 1.1 of the Bluetooth Specification and 53 types of test command interface (TCI) commands are supported. For communication between upper and lower protocol stacks, nine types of functions are prepared as an application interface (API).

#### 21.1 **Features**

- Conforms to version 1.1 of the Bluetooth Specification
- www.Das Frequency hopping within 79 channels as a form of spread-spectrum modulation
  - Supports ACL (Asynchronous Connection-Less) and SCO (Synchronous Connection-Oriented) links
  - Controls the ACL and SCO from upper layer above HCI
  - Supports all types of packets: i.e., control packets for establishing links and connections, and packets for transmission and received packets
  - Supports point-to-point and point-to-multipoint connections (piconet)
  - Mutual conversion in Voice Codec between A-law and µ-law, CVSD and linear PCM, linear PCM and A/µ-law, or A/µ-law and CVSD
  - Encryption/decryption
  - Controls three power-down modes: the Hold, Sniff and Park modes
  - Supports a direct interface with the Renesas RF ICs, such as the HD157100NP and HD157102NP
  - Supports a direct interface with the STLC7550 (ST Microelectronics) or MC145483 (Motorola) Voice Codec IC without involving the CPU
  - Includes a frequency conversion function that allows the use of a 32.768-kHz crystal resonator to provide the low-frequency clock for power-down modes
  - Supports unique TCI commands (53 types) and API functions (9 types) in addition to the HCI commands

RENESAS

Figure 21.1 shows a block diagram of the Bluetooth interface (BT).

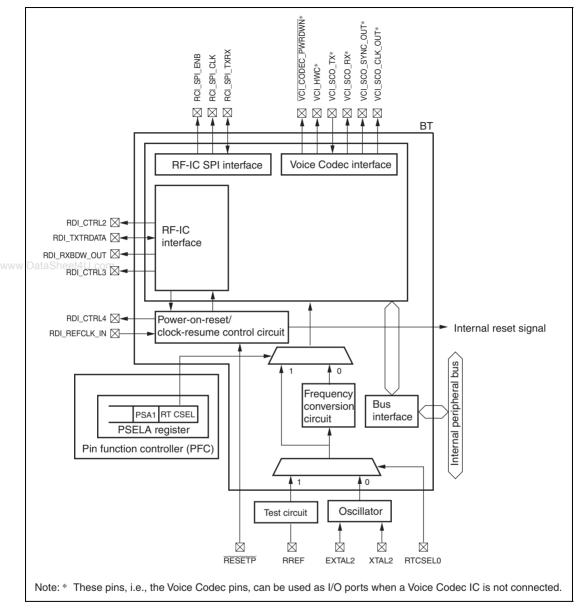

Figure 21.1 Block Diagram of Bluetooth Interface (BT)

## 21.2 Input/Output Pins

Table 21.1 summarizes the input/output pins used by the BT.

**Table 21.1 Input/Output Pins** 

Classification	Name	I/O	Function/Signal
RF-IC interface	RDI_CTRL2	Output	External power amplifier control output for supporting class 1
	RDI_TXTRDATA	I/O	Transmit/receive data I/O for the RF IC
	RDI_RXBDW_OUT	Output	Packet-control output for the RF IC
	RDI_REFCLK_IN	Input	Data I/O clock for the RF IC or main clock input for the BT
	RDI_CTRL3	Output	Strobe output to enable the oscillator in the RF IC
ataSheet4U.com	RDI_CTRL4	Output	Reset-control signal for the RF IC, power supply for the interface, or power-down control output signal
SPI interface	RCI_SPI_TXRX	I/O	SPI serial data I/O
with RF IC	RCI_SPI_CLK	Output	Clock output for the SPI interface with the RF IC
	RCI_SPI_ENB	Output	Enable output for the SPI interface with the RF IC
Voice Codec	VCI_SCO_CLK_OUT	Output	Clock output for a Voice Codec IC*1
interface	VCI_SCO_SYNC_OUT	Output	Frame-synchronization signal output for a Voice Codec IC*1*3
	VCI_SCO_RX	Output	Receive data output to a Voice Codec IC*1
	VCI_SCO_TX	Input	Transmit data input from a Voice Codec IC*1
	VCI_HWC	Output	Operation mode select output for a Voice Codec IC*1
	VCI_CODEC_ PWRDWN	Output	Power-down control output for a Voice Codec IC*1
Clock select	RTCSEL0	Input	Test Pin*2
	RREF	Input	Test Pin*2
	EXTAL2	Input	For connection to a crystal resonator
	XTAL2	Input	For connection to a crystal resonator

Notes: 1. The Voice-Codec interface pins are available for use as I/O ports (port E) when a Voice Codec IC is not connected. For details, refer to section 23, I/O Ports.

- 2. The RTCSEL0 pin should be fixed to low, and RREF pin should be pulled-up to Vcc.
- 3. As the VCI\_SCO\_SYNC\_OUT pin is multiplexed with the  $\overline{\text{BREQ}}$  pin, it should be pulled-up for the normal power-up sequence.

### 21.3 Register Description

The BT registers are accessed via firmware that is provided rather than directly by the user. Therefore, no description is given here. For the functions of the firmware, refer to the separate manual.

All registers in BT module are initialized only by the power-on reset input pin. They are not initialized by the power-on reset and manual reset generated from WDT.

#### 21.4 RF-IC Interface

The Bluetooth interface (BT) supports the direct connection with the Renesas RF ICs, such as HD157100NP and HD157102NP.

#### 21.4.1 Connection with RF ICs

Figure 21.2 shows an example of the connection of this LSI and a Renesas RF IC, such as the HD157100NP and HD157102NP. When a power-on reset signal is applied, the reset signal is sent to the BT power-on reset/clock-resume control circuit and is also sent to the RF IC via the RDI\_CTRL4 pin. After the RDI\_CTRL4 pin has fulfilled its function as a reset pin, the pin will function as a power-supply pin for the interface of the RF IC. Even after the external power-on reset signal has been negated, the reset state is maintained within this LSI.

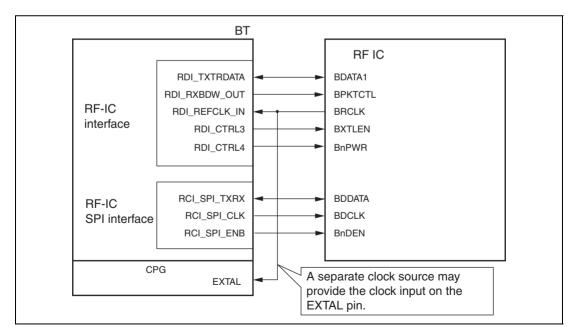

Figure 21.2 Example of Connection to RF IC

www.DataSheet4U.com

Rev. 1.00, 02/04, page 614 of 804

After it has been initialized by a reset, the RF IC starts outputting a clock signal (RDI\_REFCLK\_IN). A counter in the BT power-on-reset/clock-resume control circuit starts counting the cycles of a clock signal from the RF IC. When the value in the counter matches the required value, the RF IC is released from the reset state.

The clock signal (RDI\_REFCLK\_IN) received from the RF IC may be connected to the clock-pulse generator's EXTAL pin for use as the LSI's main clock signal. This may reduce the number of crystal oscillators required to configure the overall Bluetooth system. In this case, 13 MHz is the only available main-clock frequency for this LSI, since the frequency on the RDI\_REFCLK\_IN pin will be 13 MHz.

An independent clock can be input without connecting the output of the RDI\_REFCLK\_IN signal to the EXTAL pin\*. In this case, the main clock may run at any frequency within the range guaranteed for use with this LSI. For details on this range, refer to section 28, Electrical Characteristics. For details on the EXTAL pin, refer to section 11, Clock Pulse Generator (CPG).

Note: \* When the on-chip USBF bus-powered function is used, make sure to input an www.DataSheet4U\_cindependent clock from the RDI\_REFCLK\_IN input clock and set it to an active state.

### 21.5 Voice Codec IC Interface

This BT employs a function of the direct transfer of data with the RF IC over an SCO link without intervention of the CPU. As an external Voice Codec IC, this BT supports a direct interface with the STLC7550 (STMicroelectronics) or MC145483 (Motorola) Voice Codec IC.

#### 21.5.1 Voice Codec (STLC7550) Interface

Figure 21.3 shows an example of the connection of this BT and the Voice Codec (STLC7550). The SCLK pin of the STLC7550 is not used.

The VCI\_SCO\_SYNC\_OUT pin is multiplexed with the  $\overline{BREQ}$  pin. This pin should be pulled-up for the normal power-up sequence.

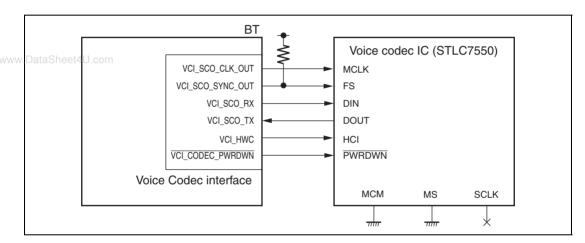

Figure 21.3 Example of Connection to Voice Codec (STLC7550)

#### 21.5.2 Voice Codec (MC145483) Interface

Figure 21.4 (1) shows an example of the connection of this BT and the Voice Codec (MC145483).

The VCI\_SCO\_SYNC\_OUT pin is multiplexed with the  $\overline{BREQ}$  pin. This pin should be pulled-up for the normal power-up sequence.

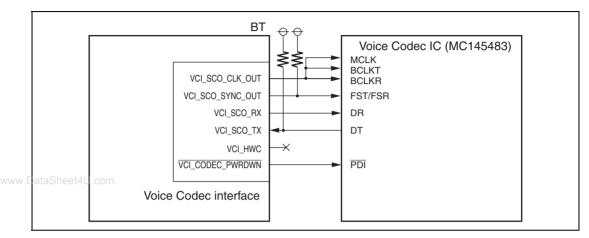

Figure 21.4 (1) Example of Connection to Voice Codec (MC145483)

Figure 21.4 (2) shows the timing chart.

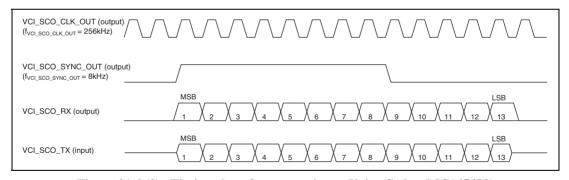

Figure 21.4 (2) Timing chart for connection to Voice Codec (MC145483)

### 21.6 Low-Frequency Clock Oscillator Interface

This BT has an interface to receive an external clock running at 32 kHz or 32.768 kHz to support Bluetooth's power-down modes (Sniff, Park, and Hold). There are four ways to supply this low-frequency clock (described below). The method is specified by the value of the RTCSEL1 bit in the PSELA. For details on the PSELA, refer to section 24, Pin Function Controller (PFC).

Here are the five possible ways to obtain the low-frequency clock signal;

- connect the 32-kHz crystal resonator to the EXTAL2 and XTAL2 pins to make the on-chip oscillator circuit provide the clock;
- connect the 32.768-kHz crystal resonator to the EXTAL2 and XTAL2 pins to make the onchip oscillation circuit provide the clock of 32.768kHz, and generate the pseudo 32-kHz clock in the frequency-conversion circuit;
- directly input 32.0-kHz from the EXTAL2 pin; and
- directly input 32.768-kHz from the EXTAL2 pin, and generate the pseudo 32-kHz clock in the frequency-conversion circuit.

DataSneet4U.com

Table 21.2 is a list of the settings.

**Table 21.2 Settings and Functions** 

RTCSEL1 Bit	Function
1	The 32-kHz crystal resonator is connected to the EXTAL2 and XTAL2 pins to make the on-chip oscillation circuit provide a signal. If not, 32.0-kHz clock should be supplied at the EXTAL2 pin.
0	The 32.768-kHz crystal resonator is connected to the EXTAL2 and XTAL2 pins to make the on-chip oscillation circuit provide a signal. If not, 32.768-kHz clock should be supplied at the EXTAL2 pin.

### 21.6.1 Using RTCSEL1 Bit to Select Clock Function

The RTCSEL1 bit in the PSELA selects whether or not the frequency-conversion circuit is activated. The frequency-conversion circuit generates a pseudo-32-kHz clock signal from a 32.768-kHz signal. Activating the frequency-conversion circuit allows the use of the 32.768-kHz crystal resonator, as used with the RTC (Real Time Clock), instead of the connection of a 32.0-kHz crystal resonator to the EXTAL2 and XTAL2 pins.

Clearing the RTCSEL1 bit to 0 activates the frequency-conversion circuit. Setting the RTCSEL1 bit makes the circuit inactive and the 32.768-kHz frequency is passed through the circuit. When the RTCSEL0 pin is set to 1, the RTCSEL1 bit should always be set to 1. The initial value of the RTCSEL1 bit is 0. For details on the PSELA, refer to section 24, Pin Function Controller (PFC).

www.DataSheet4U.com

#### 21.6.2 **Frequency-Conversion Circuit Operations**

128 cycles of a 32.768-kHz signal are equal in duration to 125 cycles of a 32-kHz signal. This is used to convert the 32.768-kHz clock into a 32-kHz clock in the following way. Firstly, the 128 cycles are divided into three states by the counting of cycles, as shown in figure 21.5. State 0 is made up of the first 43 cycles, state 1 is made up of the next 42 cycles, and state 2 is made up of the remaining 43 cycles. Then, removing a single falling edge from each of these states leaves 125 cycles. This method realizes 125 cycles from a 32.768-kHz clock within the same period as 125 cycles of the 32-kHz clock. The resulting frequency is 32000 cycles per second. A 32-kHz clock signal has thus been generated from the converted clock.

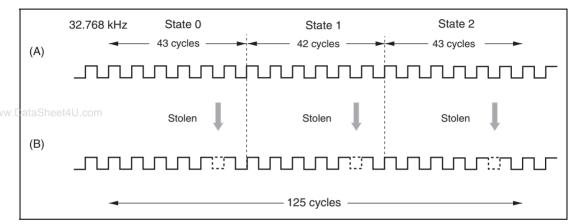

Figure 21.5 Function of Frequency-Conversion Circuit

The cumulative time differences between each cycle of a 32-kHz signal and the corresponding cycle of a pseudo-32-kHz signal are shown in figure 21.6. Since the total time for given numbers of cycles for the 32-kHz clock matches that of the pseudo 32-kHz clock every 125 cycles (see (A) and (B)), the maximum error is approximately 30 µsec.

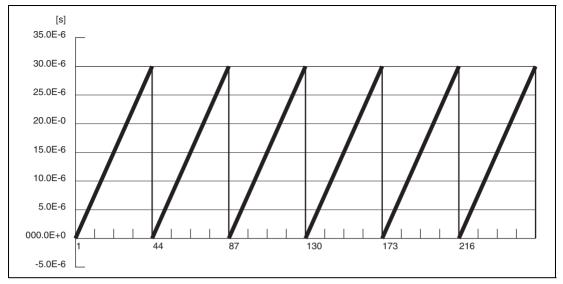

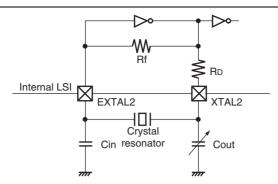

Figure 21.6 Errors in Pseudo-32-kHz Clock Obtained by Conversion from 32.768-kHz Clock

### 21.6.3 Note on Connecting External Crystal Resonator

Figure 21.7 shows a note when connecting an external crystal resonator to the EXTAL2 and XTAL2 pins.

- Notes: 1. A variable capacitor for frequency adjustment may be placed in the Cin or Cout side according to the adjustment range, stability, and so on.
  - 2. The value of the on-chip resistor is Rf = 10 M $\Omega$  and RD = 400 k $\Omega$  under the typical condition.
  - 3. The values of the Cin and Cout include floating capacitance due to wiring.
  - 4. Since the oscillation stabilization time of the crystal oscillation differs according to the constant of the mounting circuit, floating capacitance, and so on, it should be determined in consultation with the crystal resonator manufacturer.
- Place the crystal resonator and load capacitance (Cin and Cout) near this LSI (in order to prevent operation failure from occurring after a noise is externally inducted to the EXTAL2 and ataSheet4U.comXTAL2 pins).

Figure 21.7 Note on Using Crystal Resonator

#### 21.7 Power-On Reset/Clock-Resume Control Circuit

The BT of this LSI allows direct connection to the RF IC and thus minimizes the need for externally connected components.

#### 21.7.1 Power-On Reset

The clock, which is input from the HD157100NP RF IC or HD157102NP (Renesas) and is used for the interface with the RF IC, may be used as the main clock of this LSI (see figure 21.2). The RF IC (Renesas) starts outputting a clock signal after a certain period of time following the negation of a power-on reset. However, the input of a clock signal to this LSI is required to settle the oscillation of the on-chip oscillator during reset. For this reason, the LSI's internal reset signal is kept at a low level after negation of the external power-on reset signal. The internal reset signal is only negated after the required period from the application of an external clock signal has elapsed. The timing chart for this is shown in figure 21.8.

There are two types of the internal reset signals for the USB and the other modules. The required period of the internal reset signal for the USB being asserted is different from that of the others. The timing chart is shown in figure 21.8.

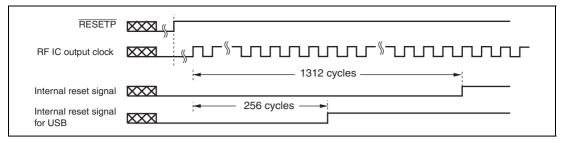

Figure 21.8 Timing Chart of Reset Signal

#### 21.7.2 Clock-Resume Control

In the power-down modes, a command that stops the output of the clock from the RF IC may be sent to the RF IC. When the clock input from the RF IC is used as the main clock of this LSI, this LSI is also stopped and the BT is operated by a separately input clock running at 32-kHz or 32.768-kHz. The LSI is equipped with a clock-resume control function to allow it to leave this mode. The sequence of this clock-resume control is given below.

- 1. The BT outputs an interrupt signal.
- 2. The BT issues a wake-up command to the RF-IC.
- 3. The INTC receives an interrupt.
- 4. The CPU is activated.

### 21.8 Bluetooth HCI/TCI Commands and API

To configure the upper protocol stack, this LSI supports host controller interface (HCI) and test control interface (TCI) commands which are defined by version 1.1 of the Bluetooth Specification, and 53 types of unique TCI commands. For details on the HCI and TCI commands, which correspond to version 1.1 of the Bluetooth Specification, refer to version 1.1 of the Bluetooth Specification. When detailed information on unique TCI commands is required, contact our sales department.

The protocol stack firmware lower than the HCI is provided as a library in this LSI, and this enables the Bluetooth interface easily to be added to a developed program. In addition, as the application interface (API) of this library bases on H4 of the Bluetooth Specification, it is easy to be applied to this LSI. As the API function of this LSI, 9 types of functions are prepared. For details, contact our sales department.

# Section 22 D/A Converter (DAC)

#### 22.1 Features

This LSI incorporates a two-channel D/A converter (DAC) with the following features.

- 8-bit resolution
- Two output channels
- Conversion time: Min. 10 µs (when load capacitance is 20 pF)
- Output voltage: 0 V to AVcc (analog power supply)

Figure 22.1 shows the block diagram of the DAC.

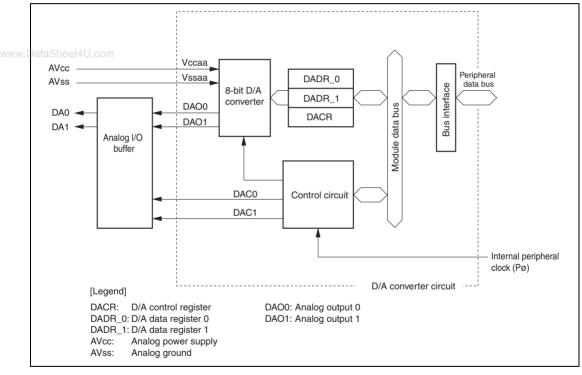

Figure 22.1 Block Diagram of DAC

### 22.2 Input/Output Pins

Table 22.1 summarizes the input/output pins used by the DAC.

**Table 22.1 Pin Configuration** 

Pin Name	I/O	Function
Avcc	_	Analog block power supply and D/A conversion reference voltage
Avss	_	Analog block ground
DA0	Output	Channel 0 analog output
DA1	Output	Channel 1 analog output

# 22.3 Register Descriptions

The DAC has the following registers. Refer to section 27, List of Registers, for more details of the paddresses of these registers and the state of these registers in each processor mode.

- D/A data register 0 (DADR\_0)
- D/A data register 1 (DADR\_1)
- D/A control register (DACR)

### 22.3.1 D/A Data Registers 0 and 1 (DADR\_0, DADR\_1)

DADR\_0 and DADR\_1 are 8-bit readable/writable registers that store data for D/A conversion. When the D/A output enable bits (DAOE1, DAOE0) of the DA control register (DACR) are set to 1, the contents of the D/A data register (DADR\_0, DADR\_1) are converted and output to analog output pins (DA0, DA1). The D/A data register (DADR\_0, DADR\_1) is initialized to H'00 at a reset. Note that DADR\_0 and DADR\_1 are not initialized in software standby or module standby.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	_	H'00	R/W	8-bit registers that store data for D/A conversion.

#### 22.3.2 D/A Control Register (DACR)

DACR is an 8-bit readable/writable register that controls the DAC operation. DACR is initialized to H'3F at a reset. Note that DACR is not initialized in software standby or module standby.

		Initial		
Bit	Bit Name	Value	R/W	Description
7	DAOE1	0	R/W	Controls D/A conversion for channel 1 and analog output.
				0: D/A conversion for channel 1 and analog output (DA1) are disabled
				1: D/A conversion for channel 1 and analog output (DA1) are enabled
6	DAOE0	0	R/W	Controls D/A conversion for channel 0 and analog output.
				0: D/A conversion for channel 0 and analog output (DA0) are disabled
itaSheet4				1: D/A conversion for channel 0 and analog output (DA0) are enabled
5 to 0	_	All 1	R	Reserved
				These bits are always read as 1. The write value should always be 1. If 0 is written to these bits, correct operation cannot be guaranteed.

### 22.4 Operation

The DAC incorporates two D/A channels that can operate individually.

The DAC executes D/A conversion while analog output is enabled by the D/A control register (DACR). If the D/A data registers (DADR\_0 and DADR\_1) are modified, the D/A converter immediately initiates the new data conversion. When the DAOE1 and DAOE0 bits in the DACR register are set to 1, D/A conversion results are output.

An example of D/A conversion for channel 0 is shown below. The operation timing is shown in figure 22.2.

- 1. Write conversion data to DADR\_0.
- When the DAOE0 bit in DACR is set to 1, D/A conversion starts. The results are output after
  the conversion has ended. The output value will be (DADR\_0 contents/256) × AVcc.
  The conversion results are output continuously until DADR\_0 is modified or the DAOE0 bit is
  cleared to 0.

- 3. When D/A data register 0 (DADR\_0) is modified, the conversion starts again. The results are output after the conversion has ended.
- 4. When the DAOE0 in the DACR bit is cleared to 0, analog output is disabled (high-impedance state).

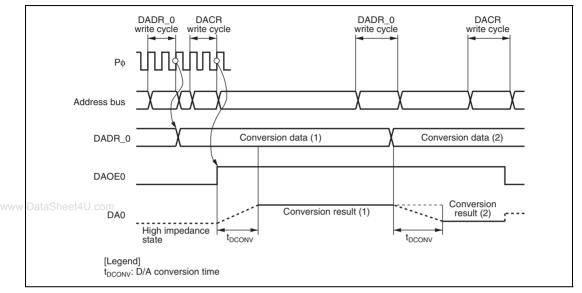

Figure 22.2 D/A Converter Operation Example

# Section 23 I/O Ports

This LSI has six I/O ports (ports A, B, D, E, G and H). All port pins are multiplexed with other pin functions (the pin function controller (PFC) handles the selection of pin functions and pull-up MOS control). Each port has a data register which stores data for the pins.

#### 23.1 Port A

Port A is a 7-bit input/output port with the pin configuration shown in figure 23.1. Each pin has an input pull-up MOS, which is controlled by the port A control register (PACR) in the PFC.

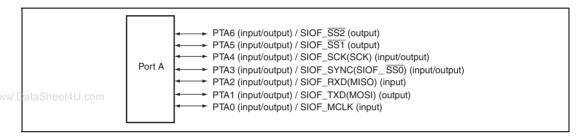

Figure 23.1 Port A

### 23.1.1 Register Description

Port A has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port A data register (PADR)

### 23.1.2 Port A Data Register (PADR)

PADR is a 7-bit readable/writable register that stores data for pins PTA6 to PTA0. Bits PA6DT to PA0DT correspond to pins PTA6 to PTA0. When the pin function is general output port, if the port is read, the value of the corresponding PADR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

Bit	Bit Name	Initial Value	R/W	Description
7	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
6	PA6DT	0	R/W	Table 23.1 shows the function of PADR.
5	PA5DT	0	R/W	_
4	PA4DT	0	R/W	_
DajaShee	PA3DT	0	R/W	_
2	PA2DT	0	R/W	_
1	PA1DT	0	R/W	_
0	PA0DT	0	R/W	_

Table 23.1 Port A Data Register (PADR) Read/Write Operations

### PACR State\*1

PAnMD1*2	PAnMD0*2	Pin State	Read	Write
0	0	Other function	PADR value	Value is written to PADR, but does not affect pin state.
	1	Output	PADR value	Write value is output from pin.
1	0	Input (Pull-up MOS on)	Pin state	Value is written to PADR, but does not affect pin state.
	1	Input (Pull-up MOS off)	Pin state	Value is written to PADR, but does not affect pin state.

Notes: 1. For details on PACR, refer to section 24, Pin Function Controller (PFC).

2. n = 0 to 6

#### 23.2 Port B

Port B is an 8-bit input/output port with the pin configuration shown in figure 23.2. Each pin has an input pull-up MOS, which is controlled by the port B control register (PBCR) in the PFC.

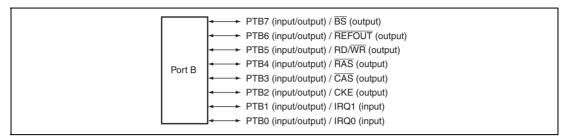

Figure 23.2 Port B

#### 23.2.1 Register Description

ataShoot411 com

Port B has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port B data register (PBDR)

### 23.2.2 Port B Data Register (PBDR)

PBDR is an 8-bit readable/writable register that stores data for pin PTB7 to PTB0. Bits PB7DT to PB0DT correspond to pins PTB7 to PTB0. When the pin function is general output port, if the port is read, the value of the corresponding PBDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7DT	0	R/W	
6	PB6DT	0	R/W	Table 23.2 shows the function of PBDR.
5	PB5DT	0	R/W	
4	PB4DT	0	R/W	_
3	PB3DT	0	R/W

<sup>2.</sup> n = 0 to 7

#### 23.3 Port D

Port D is a 6-bit input/output port with the pin configuration shown in figure 23.3. Each pin has an input pull-up MOS, which is controlled by the port D control register (PDCR) in the PFC.

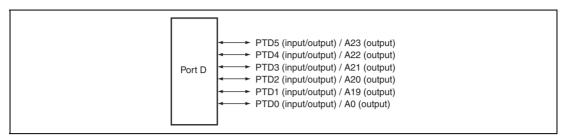

Figure 23.3 Port D

### 23.3.1 Register Description

Port D has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port D data register (PDDR)

### 23.3.2 Port D Data Register (PDDR)

PDDR is a 6-bit readable/writable register that stores data for pins PTD5 to PTD0. Bits PD5DT to PD0DT correspond to pins PTD5 to PTD0. When the pin function is general output port, if the port is read, the value of the corresponding PDDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
5	PD5DT	0	R/W	Table 23.3 shows the function of PDDR.

1	1 0 Input (F MOS of		Pin state	Value is written to PDDR, but does not affect pin state.
	1	Input (Pull-up MOS off)	Pin state	Value is written to PDDR, but does not affect pin state.

Notes: 1. For details on PDCR, refer to section 24, Pin Function Controller (PFC).

2. n = 0 to 5

www.DataSheet4U.com

#### 23.4 Port E

Port E is a 7-bit input/output port with the pin configuration shown in figure 23.4. Each pin has an input pull-up MOS, which is controlled by the port E control register (PECR) in the PFC.

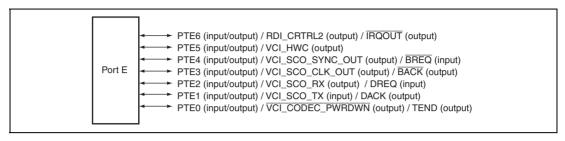

Figure 23.4 Port E

#### 23.4.1 Register Description

otoChoot411 com

Port E has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port E data register (PEDR)

#### 23.4.2 Port E Data Register (PEDR)

PEDR is a 7-bit readable/writable register that stores data for pins PTE6 to PTE0. Bits PE6DT to PE0DT correspond to pins PTE6 to PTE0. When the pin function is general output port, if the port is read, the value of the corresponding PEDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

		Initial		
Bit	Bit Name	Value	R/W	Description
7	_	0	R	Reserved
				This bit is always read as 0. The write value should always be 0. If 1 is written to this bit, correct operation cannot be guaranteed.
6	PE6DT	0	R/W	Table 23.4 shows the function of PEDR.

0	0	Other function	PEDR value	Value is written to PEDR, but does not affect pin state.
	1	Output	PEDR value	Write value is output from pin.
1	0	Input (Pull-up MOS on)	Pin state	Value is written to PEDR, but does not affect pin state.
	1	Input (Pull-up MOS off)	Pin state	Value is written to PEDR, but does not affect pin state.

Notes: 1. For details on PECR, refer to section 24, Pin Function Controller (PFC).

2. n = 0 to 6

### 23.5 Port G

Port G is a 5-bit input/output port with the pin configuration shown in figure 23.5. Each pin has an input pull-up MOS, which is controlled by the port G control register (PGCR) in the PFC.

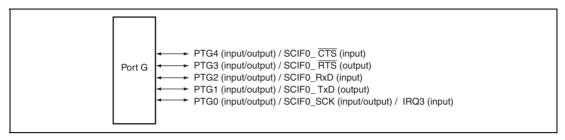

Figure 23.5 Port G

#### 23.5.1 Register Description

otoChoot411 com

Port G has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port G data register (PGDR)

### 23.5.2 Port G Data Register (PGDR)

PGDR is a 5-bit readable/writable register that stores data for pins PTG4 to PTG0. Bits PG4DT to PG0DT correspond to pins PTG4 to PTG0. When the pin function is general output port, if the port is read, the value of the corresponding PGDR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read.

If the TE or RE bit is set to 1 in the serial control register \_0 (SCSCR\_0) of the serial communication interface with FIFO (SCIF), the SCIF0\_TxD or SCIF0\_RxD is selected regardless of the PGCR register setting.

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	_	All 0	R	Reserved
DataChan	MILeon			These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
4	PG4DT	0	R/W	Table 23.5 shows the function of PGDR.
3	PG3DT	0	R/W	_

0	0	Other function	PGDR value	Value is written to PGDR, but does not affect pin state.
	1	Output	PGDR value	Write value is output from pin.
1	0	Input (Pull-up MOS on)*3	Pin state	Value is written to PGDR, but does not affect pin state.
	1	Input (Pull-up MOS off)*3	Pin state	Value is written to PGDR, but does not affect pin state.

RENESAS

Notes: 1. For details on PGCR, refer to section 24, Pin Function Controller (PFC).

- 2. n = 0 to 4
- 3. When n = 1, pin state is a high impedance (output).

www.DataSheet4U.com

#### 23.6 Port H

Port H is a 5-bit input/output port with the pin configuration shown in figure 23.6. Each pin has an input pull-up MOS, which is controlled by the port H control register (PHCR) in the PFC.

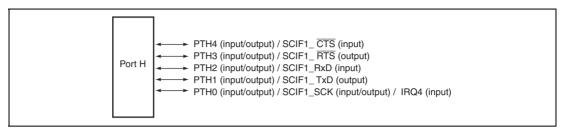

Figure 23.6 Port H

### 23.6.1 Register Description

Port H has the following register. Refer to section 27, List of Registers, for the address of this register and state of this register in each processing mode.

• Port H data register (PHDR)

#### 23.6.2 Port H Data Register (PHDR)

PHDR is a 5-bit readable/writable register that stores data for pins PTH4 to PTH0. Bits PH4DT to PH0DT correspond to pins PTH4 to PTH0. When the function is general output port, if the port is read, the value of the corresponding PHDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

If the TE or RE bit is set to 1 in the serial control register \_1 (SCSCR\_1) of the serial communication interface with FIFO (SCIF), the SCIF1\_TxD or SCIF1\_RxD is selected regardless of the PHCR register setting.

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.

1	0 Input (Pull-up F MOS on)*3		Pin state	Value is written to PHDR, but does not affect pin state.
	1	Input (Pull-up MOS off)*3	Pin state	Value is written to PHDR, but does not affect pin state.

Notes: 1. For details on PHCR, refer to section 24, Pin Function Controller (PFC).

- 2. n = 0 to 4
- 3. When n = 1, pin state is a high impedance (output).

www.DataSheet4U.com

# Section 24 Pin Function Controller (PFC)

### 24.1 Overview

Some pins in this LSI are multiplexed with I/O port functions (for details on this I/O port refer to section 23, I/O Ports). The pin function controller (PFC) consists of registers to select the pin functions and I/O directions of multiplex pins. Pin functions and I/O directions can be individually selected for every pin regardless of the LSI operating mode. Table 24.1 lists the multiplex pins of this LSI. In the table, pin functions in the shaded column can be used immediately after resetting.

**Table 24.1 Multiplex Pins** 

Function 1 (Related Module)	Function 2 (Related Module)	Function 3 (Related Module)

### 24.2 Register Descriptions

PFC has the following registers. For details on register addresses and register states in each operation mode, refer to section 27, List of Registers.

- Port A control register (PACR)
- Port B control register (PBCR)
- Port D control register (PDCR)
- Port E control register (PECR)
- Port G control register (PGCR)
- Port H control register (PHCR)
- Pin select register A (PSELA)
- I/O buffer Hi-Z control register A (HIZCRA)
- Noise canceller control register (NCCR)

Note: The PFC registers are not initialized by a manual reset and hold the contents.

#### 24.2.1 Port A Control Register (PACR)

PACR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15, 14	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
13	PA6MD1	1	R/W	PTA6 Mode
12	PA6MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
11	PA5MD1	1	R/W	PTA5 Mode
10	PA0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

		Initial		
Bit	Bit Name	Value*	R/W	Description
9	PA4MD1	1	R/W	PTA4 Mode
8	PA4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
7	PA3MD1	1	R/W	PTA3 Mode
6	PA3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
5	PA2MD1	1	R/W	PTA2 Mode
4	PA2MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
3	PA1MD1	1	R/W	PTA1 Mode
2	PA1MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
1	PA0MD1	1	R/W	PTA0 Mode
0	PA0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

## 24.2.2 Port B Control Register (PBCR)

PBCR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15	PB7MD1	0	R/W	PTB7 Mode
14	PB7MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
13	PB6MD1	0	R/W	PTB6 Mode
12	PB6MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
taSheet41				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
11	PB5MD1	0	R/W	PTB5 Mode
10	PB5MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
9	PB4MD1	0	R/W	PTB4 Mode
8	PB4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
7	PB3MD1	0	R/W	PTB3 Mode
6	PB3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
5	PB2MD1	0	R/W	PTB2 Mode
4	PB2MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

		Initial		
Bit	Bit Name	Value*	R/W	Description
3	PB1MD1	1	R/W	PTB1 Mode
2	PB1MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
1	PB0MD1	1	R/W	PTB0 Mode
0	PB0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

# 24.2.3 Port D Control Register (PDCR)

PDCR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15 to	_	All 0	R	Reserved
12				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
11	PD5MD1	0	R/W	PTD5 Mode
10	PD5MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
9	PD4MD1	0	R/W	PTD4 Mode
8	PD4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

		Initial		
Bit	Bit Name	Value*	R/W	Description
7	PD3MD1	0	R/W	PTD3 Mode
6	PD3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
5	PD2MD1	0	R/W	PTD2 Mode
4	PD2MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
3	PD1MD1	0	R/W	PTD1 Mode
2	PD1MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
1	PD0MD1	0	R/W	PTD0 Mode
0	PD0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

## 24.2.4 Port E Control Register (PECR)

PECR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15, 14	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
13	PE6MD1	1	R/W	PTE6 Mode
12	PE6MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
Nata Shaat	411.000			11: Port input (pull-up MOS: Off)
11	PE5MD1	1	R/W	PTE5 Mode
10	PE5MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
9	PE4MD1	0	R/W	PTE4 Mode
8	PE4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
7	PE3MD1	0	R/W	PTE3 Mode
6	PE3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
5	PE2MD1	1	R/W	PTE2 Mode
4	PE2MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Bit	Bit Name	Initial Value*	R/W	Description
3	PE1MD1	1	R/W	PTE1 Mode
2	PE1MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
1	PE0MD1	1	R/W	PTE0 Mode
0	PE0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

# www.Da24.2:5:4U.Port G Control Register (PGCR)

PGCR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15 to 1	10 —	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
9	PG4MD1	1	R/W	PTG4 Mode
8	PG4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
7	PG3MD1	1	R/W	PTG3 Mode
6	PG3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

		Initial		
Bit	Bit Name	Value*	R/W	Description
5	PG2MD1	1	R/W	PTG2 Mode
4	PG2MD0	0	R/W	When the RE bit in the SCSCR_0 register is 0:
				00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
				When the RE bit in the SCSCR_0 register is 1:
				Regardless of the PG2MD1 or PG2MD0 bit setting, other functions (SCIF0_RxD) is selected.
3	PG1MD1	1	R/W	PTG1 Mode
2	PG1MD0	0	R/W	When the TE bit in the SCSCR_0 register is 0:
				00: Other functions (see table 24.1)
				01: Port output
	heet4U.com			10: Output high-impedance state
				11: Output high-impedance state
				When the TE bit in the SCSCR_0 register is 1:
				Regardless of the PG1MD1 or PG1MD0 bit setting, other function (SCIF0_TxD) is selected.
1	PG0MD1	1	R/W	PTG0 Mode
0	PG0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

# 24.2.6 Port H Control Register (PHCR)

PHCR is a 16-bit readable/writable register that selects the pin function and input pull-up MOS control.

Bit	Bit Name	Initial Value*	R/W	Description
15 to10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
9	PH4MD1	1	R/W	PTH4 Mode
8	PH4MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
toSboot41	Loom			11: Port input (pull-up MOS: Off)
7	PH3MD1	1	R/W	PTH3 Mode
6	PH3MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
5	PH2MD1	1	R/W	PTH2 Mode
4	PH2MD0	0	R/W	When the RE bit in the SCSCR_1 register is 0:
				00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
				11: Port input (pull-up MOS: Off)
				When the RE bit in the SCSCR_1 is 1:
				Regardless of the PH2MD1 or PH2MD0 bit setting, other functions (SCIF1_RxD) is selected.

		Initial		
Bit	Bit Name	Value*	R/W	Description
3	PH1MD1	1	R/W	PTH1 Mode
2	PH1MD0	0	R/W	When the TE bit in the SCSCR_1 register is 0:
				00: Other functions (see table 24.1)
				01: Port output
				10: Output high-impedance state
				11: Output high-impedance state
				When the TE bit in the SCSCR_1 register is 1:
				Regardless of the PH1MD1 or PH1MD0 bit setting, other function (SCIF1_TxD) is selected.
1	PH0MD1	1	R/W	PTH0 Mode
0	PH0MD0	0	R/W	00: Other functions (see table 24.1)
				01: Port output
				10: Port input (pull-up MOS: On)
	et4U.com			11: Port input (pull-up MOS: Off)

Note: \* This register is not initialized by a manual reset and holds the contents.

### 24.2.7 Pin Select Register A (PSELA)

PSELA is a 16-bit readable/writable register that has two purposes.

Bit 0 (RTCSEL1) selects a frequency for the low-frequency clock source that is used in the Bluetooth interface (BT). When a 32.000kHz clock is selected, the clock is input to the BT. When 32.768-kHz clock is selected, the clock is converted into a pseudo 32.000kHz clock by the frequency conversion circuit. For details, refer to section 21, Bluetooth Interface (BT).

Bits 1 to 8 select the function for a pin multiplexed with two or more other functions. When one of the other functions are used, the corresponding bit in the PSELA should be specified before the other function is specified by the port control register.

Setting example: To use IRQOUT function in the PTE6/RDI CTRL2/IRQOUT pin

- 1. Write 1 to the PSA8 bit in the PSELA register.
- 2. Set the PE6MD1 and PE6MD0 bits in the port E control register (PECR) to (0.0) (other functions).

Bit	Bit Name	Initial Value*	R/W	Description
15 to 9	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
8	PSA8	0	R/W	RDI_CTRL2/IRQOUT Select
				0 : Selects RDI_CTRL2
				1 : Selects IRQOUT
7	PSA7	1	R/W	VCI_SCO_SYNC_OUT/BREQ Select
				0 : Selects VCI_SCO_SYNC_OUT
				1 : Selects BREQ
6	PSA6	1	R/W	VCI_SCO_CLK_OUT/BACK Select
				0 : Selects VCI_SCO_CLK_OUT
				1 : Selects BACK
t <b>5</b> Sheet4L	PSA5	0	R/W	VCI_SCO_RX/DREQ Select
				0: Selects VCI_SCO_RX
				1: Selects DREQ
4	PSA4	0	R/W	VCI_SCO_TX/DACK Select
				0: Selects VCI_SCO_TX
				1: Selects DACK
3	PSA3	0	R/W	VCI_CODEC_PWRDWN/TEND Select
				0 : Selects VCI_CODEC_PWRDWN
				1 : Selects TEND
2	PSA2	0	R/W	SCIF0_SCK/IRQ3 Select
				0 : Selects SCIF0_SCK
				1 : Selects IRQ3
1	PSA1	0	R/W	SCIF1_SCK/IRQ4 Select
				0 : Selects SCIF1_SCK
				1 : Selects IRQ4
0	RTCSEL 1	0	R/W	Low-frequency clock frequency Select
				0 : Selects 32.768-kHz
				1 : Selects 32.000-kHz

Note: \* This register is not initialized by a manual reset and holds the contents.

## 24.2.8 I/O Buffer Hi-Z Control Register A (HIZCRA)

HIZCRA is a 16-bit readable/writable register that controls Hi-Z and pull-up for pins for every function unit\*.

Note: \* Even if the output Hi-Z state is specified in the HIZCRA, the pull-up MOS remains turned on when port input (pull-up MOS: On) is selected in the PnCR.

		Initial		
Bit	Bit Name	Value*	R/W	Description
15 to 9	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. When writing 1, the operation of this LSI is not guaranteed.
8	HIZA8	0	R/W	Controls high impedance for pins multiplexed with SIOF related signals (SIOF_RXD(MISO)/SIOF_TXD(MOSI)/SIOF_SYNC(SIOF_SS0)/SIOF_SS1/SIOF_SS2).
ataSheet	4U.com			0 : I/O buffer enters normal operation mode
				<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>
7	HIZA7	0	R/W	Controls high impedance for pins multiplexed with SIOF related signals (SIOF_MCLK/SIOF_SCK(SCK))
				0 : I/O buffer enters normal operation mode
				<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>
6	HIZA6	0	R/W	Controls high impedance for pins multiplexed with SCIF0 related signals(SCIF0_RxD/SCIF0_TxD/SCIF0_RTS/SCIF0_CTS)
				0 : I/O buffer enters normal operation mode
				1 : Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.
5	HIZA5	0	R/W	Controls high impedance for pins multiplexed with SCIF0 related signals (SCIF0_SCK)
				0 : I/O buffer enters normal operation mode
				<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>

		Initial		
Bit	Bit Name	Value*	R/W	Description
4	HIZA4	0	R/W	Controls high impedance for pins multiplexed with SCIF1 related signals (SCIF1_RxD/SCIF1_TxD/SCIF1_RTS/SCIF1_CTS)
				0 : I/O buffer enters normal operation mode
				<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>
3	HIZA3	0	R/W	Controls high impedance for pins multiplexed with SCIF1 related signals (SCIF1_SCK)
				0 : I/O buffer enters normal operation mode
				<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>
2	HIZA2	0	R/W	Controls high impedance for pins multiplexed with RD/WR/RAS/CAS/CKE
				0 : I/O buffer enters normal operation mode
	et4U.com			<ol> <li>Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.</li> </ol>
1	HIZA1	0	R/W	Controls high impedance for IRQ2 pins
				0 : I/O buffer enters normal operation mode
				1 : Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.*1
0	HIZA0	0	R/W	Controls high impedance for IRQ0 pins
				0 : I/O buffer enters normal operation mode.
				1 : Input buffer is an OFF state, and I/O buffer enters output Hi-Z state.*2

Notes: 1. This register is not initialized by a manual reset and holds the contents.

2. With this setting Shmidt input is selected.

## 24.2.9 Noise Canceller Control Register (NCCR)

NCCR is a readable/writable 16-bit register that controls the Noise Canceller On/Off state.

Bit	Bit Name	Initial Value*	R/W	Description
15 to 1	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
0	NCCR0	0	R/W	Controls the Noise Canceller in the TRST, NMI and IRQ registers.
				0 : Noise Canceller off
				1 : Noise Canceller on

Note: \* This register is not initialized by a manual reset and holds the contents.

www DataSheet4U com

# Section 25 User Break Controller

The user break controller (UBC) provides functions that simplify program debugging. These functions make it easy to design an effective self-monitoring debugger, enabling the chip to debug programs without using an in-circuit emulator. Break conditions that can be set in the UBC are instruction fetch or data read/write access, data size, data contents, address value, and stop timing in the case of instruction fetch.

#### 25.1 Features

The UBC has the following features:

1. The following break comparison conditions can be set.

Number of break channels: two channels (channels A and B)

User break can be requested as either the independent or sequential condition on channels A and B (sequential break setting: channel A and then channel B match with break conditions, but not in the same bus cycle).

— Address

Comparison bits are maskable in 1-bit units; user can mask addresses at lower 12 bits (4-k page), lower 10 bits (1-k page), or any size of page, etc.

One of the four address buses (L-bus address (LAB), I-bus address(IAB), X-memory address bus (XAB), and Y-memory address bus (YAB)) can be selected.

— Data

Only on channel B, 32-bit maskable.

One of the four data buses (L-bus data (LDB), I-bus data (IDB), X-memory data bus (XDB) and Y-memory data bus (YDB)) can be selected.

— Bus cycle

Instruction fetch or data access

- Read/write
- Operand size

Byte, word, and longword

- 2. A user-designed user-break condition exception processing routine can be run.
- 3. In an instruction fetch cycle, it can be selected that a break is set before or after an instruction is executed.
- 4. Maximum repeat times for the break condition (only for channel B):  $2^{12} 1$  times.
- 5. Eight pairs of branch source/destination buffers.

Figure 25.1 shows a block diagram of the UBC.

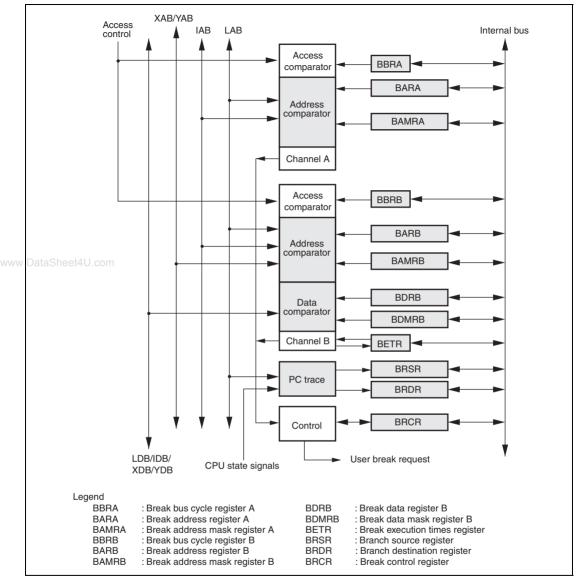

Figure 25.1 Block Diagram of User Break Controller

# 25.2 Register Descriptions

The UBC has the following registers. For details on register addresses and access sizes, refer to section 27, List of Registers.

- Break address register A (BARA)
- Break address mask register A (BAMRA)
- Break bus cycle register A (BBRA)
- Break address register B (BARB)
- Break address mask register B (BAMRB)
- Break bus cycle register B (BBRB)
- Break data register B (BDRB)
- Break data mask register B (BDMRB)
- Break control register (BRCR)
- Execution times break register (BETR)
- www.DasS Branch source register (BRSR)
  - Branch destination register (BRDR)

### 25.2.1 Break Address Register A (BARA)

BARA is a 32-bit readable/writable register. BARA specifies the address used as a break condition in channel A.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BAA31 to BAA0	All 0	R/W	Break Address A
				Store the address on the LAB or IAB specifying break conditions of channel A.

## 25.2.2 Break Address Mask Register A (BAMRA)

BAMRA is a 32-bit readable/writable register. BAMRA specifies bits masked in the break address specified by BARA.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BAMA31 to BAMA0	All 0	R/W	Break Address Mask A
				Specify bits masked in the channel A break address bits specified by BARA (BAA31 to BAA0).
				0: Break address bit BAAn of channel A is included in the break condition
				1: Break address bit BAAn of channel A is masked and is not included in the break condition
				Note: $n = 31 \text{ to } 0$

DataSheet4U.com

## 25.2.3 Break Bus Cycle Register A (BBRA)

BBRA is a 16-bit readable/writable register, which specifies (1) L bus cycle or I bus cycle, (2) instruction fetch or data access, (3) read or write, and (4) operand size in the break conditions of channel A.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
7	CDA1	0		L Bus Cycle/I Bus Cycle Select A
6	CDA0	0	R/W	Select the L bus cycle or I bus cycle as the bus cycle of the channel A break condition.
				00: Condition comparison is not performed
				01: The break condition is the L bus cycle
				10: The break condition is the I bus cycle
				11: The break condition is the L bus cycle

Bit	Bit Name	Initial Value	R/W	Description
5	IDA1	0	R/W	Instruction Fetch/Data Access Select A
4	IDA0	0	R/W	Select the instruction fetch cycle or data access cycle as the bus cycle of the channel A break condition.
				00: Condition comparison is not performed
				01: The break condition is the instruction fetch cycle
				10: The break condition is the data access cycle
				11: The break condition is the instruction fetch cycle or data access cycle
3	RWA1	0	R/W	Read/Write Select A
2	RWA0	0	R/W	Select the read cycle or write cycle as the bus cycle of the channel A break condition.
				00: Condition comparison is not performed
				01: The break condition is the read cycle
				10: The break condition is the write cycle
				11: The break condition is the read cycle or write cycle
1	SZA1	0	R/W	Operand Size Select A
0	SZA0	0	R/W	Select the operand size of the bus cycle for the channel A break condition.
				00: The break condition does not include operand size
				01: The break condition is byte access
				10: The break condition is word access
				11: The break condition is longword access

## 25.2.4 Break Address Register B (BARB)

BARB is a 32-bit readable/writable register. BARB specifies the address used as a break condition in channel B. Control bits CDB1, CDB0, XYE, and XYS in BBRB select one of the four address buses for break condition B.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BAB31 to BAB 0	All 0	R/W	Break Address B
DataShee				Stores an address which specifies a break condition in channel B.  If the I bus or L bus is selected in BBRB, an IAB or LAB address is set in BAB31 to BAB0.  If the X memory is selected in BBRB, the values in bits 15 to 1 in XAB are set in BAB31 to BAB17. In this case, the values in BAB16 to BAB0 are arbitrary.  If the Y memory is selected in BBRB, the values in bits 15 to 1 in YAB are set in BAB15 to BAB1. In this case, the values in BAB31 to BAB16 are arbitrary.

Table 25.1 Specifying Break Address Register

Bus Selection in BBRB	BAB31 to BAB17	BAB16	BAB15 to BAB1	BAB0
L bus		LAB31 to	o LAB0	
I bus		IAB31 to	o IAB0	
X bus	XAB15 to XAB1	Don't care	Don't care	Don't care
Y bus	Don't care	Don't care	YAB15 to YAB1	Don't care

## 25.2.5 Break Address Mask Register B (BAMRB)

BAMRB is a 32-bit readable/writable register. BAMRB specifies bits masked in the break address specified by BARB.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BAMB31 to BAMB0	All 0	R/W	Break Address Mask B
				Specifies bits masked in the break address of channel B specified by BARB (BAB31 to BAB0).
				0: Break address BABn of channel B is included in the break condition
				1: Break address BABn of channel B is masked and is not included in the break condition
				Note: $n = 31 \text{ to } 0$

www.DataShoot411.com

## 25.2.6 Break Data Register B (BDRB)

BDRB is a 32-bit readable/writable register. The control bits CDB1, CDB0, XYE, and XYS in BBRB select one of the four data buses for break condition B.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BDB31 to BDB0	All 0	R/W	Break Data Bit B
				Stores data which specifies a break condition in channel B.  If the I bus is selected in BBRB, the break data on IDB is set in BDB31 to BDB0.  If the L bus is selected in BBRB, the break data on LDB is set in BDB31 to BDB0.  If the X memory is selected in BBRB, the break data in bits 15 to 0 in XDB is set in BDB31 to BDB16. In this case, the values in BDB15 to BDB0 are arbitrary.  If the Y memory is selected in BBRB, the break data in bits 15 to 0 in YDB are set in BDB15 to BDB0. In this case, the values in BDB31 to BDB16 are arbitrary.

Table 25.2 Specifying Break Data Register

Bus Selection in BBRB	BDB31 to BDB16	BDB15 to BDB0
L bus		LDB31 or LDB0
I bus		IDB31 to IDB0
X bus	XDB15 to XDB0	Don't care
Y bus	Don't care	YDB15 to YDB0

Notes: 1. Specify an operand size when including the value of the data bus in the break condition.

- 2. When the byte size is selected as a break condition, the same byte data must be set in bits 15 to 8 and 7 to 0 in BDRB as the break data.
- Set the data in bits 31 to 16 when including the value of the data bus as an L-bus break condition for the MOVS.W @-As,Ds, MOVS.W @As,Ds, MOVS.W @As+,Ds, or MOVS.W @As+lx,Ds instruction.

#### 25.2.7 Break Data Mask Register B (BDMRB)

JalaSHEEL4U.COIII

BDMRB is a 32-bit readable/writable register. BDMRB specifies bits masked in the break data specified by BDRB.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BDMB31 to BDMB 0	All 0	R/W	Break Data Mask B
				Specifies bits masked in the break data of channel B specified by BDRB (BDB31 to BDB0).
				0: Break data BDBn of channel B is included in the break condition
				Break data BDBn of channel B is masked and is not included in the break condition
				Note: $n = 31 \text{ to } 0$

Notes: 1. Specify an operand size when including the value of the data bus in the break condition.

- 2. When the byte size is selected as a break condition, the same byte data must be set in bits 15 to 8 and 7 to 0 in BDRB as the break mask data in BDMRB.
- Set the mask data in bits 31 to 16 when including the value of the data bus as an L-bus break condition for the MOVS.W @-As,Ds, MOVS.W @As,Ds, MOVS.W @As+,Ds, or MOVS.W @As+Ix,Ds instruction.

## 25.2.8 Break Bus Cycle Register B (BBRB)

Break bus cycle register B (BBRB) is a 16-bit readable/writable register, which specifies (1) X bus or Y bus, (2) L bus cycle or I bus cycle, (3) instruction fetch or data access, (4) read or write, and (5) operand size in the break conditions of channel B.

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
9	XYE	0	R/W	Selects the X memory bus or Y memory bus as the channel B break condition. Note that this bit setting is enabled only when the L bus is selected with the CDB1 and CDB0 bits. Selection between the X memory bus and Y memory bus is done by the XYS bit.
)ataSheet4l				Selects L bus for the channel B break condition unconditionally
				Selects X/Y memory bus for the channel B break condition
8	XYS	0	R/W	Selects the X bus or the Y bus as the bus of the channel B break condition.
				0: Selects the X bus for the channel B break condition
				1: Selects the Y bus for the channel B break condition
7	CDB1	0	R/W	L Bus Cycle/I Bus Cycle Select B
6	CDB0	0	R/W	Select the L bus cycle or I bus cycle as the bus cycle of the channel B break condition.
				00: Condition comparison is not performed
				01: The break condition is the L bus cycle
				10: The break condition is the I bus cycle
				11: The break condition is the L bus cycle
5	IDB1	0	R/W	Instruction Fetch/Data Access Select B
4	IDB0	0	R/W	Select the instruction fetch cycle or data access cycle as the bus cycle of the channel B break condition.
				00: Condition comparison is not performed
				01: The break condition is the instruction fetch cycle
				10: The break condition is the data access cycle
				11: The break condition is the instruction fetch cycle or data access cycle

		Initial		
Bit	Bit Name	Value	R/W	Description
3	RWB1	0	R/W	Read/Write Select B
2	RWB0	0	R/W	Select the read cycle or write cycle as the bus cycle of the channel B break condition.
				00: Condition comparison is not performed
				01: The break condition is the read cycle
				10: The break condition is the write cycle
				11: The break condition is the read cycle or write cycle
1	SZB1	0	R/W	Operand Size Select B
0	SZB0	0	R/W	Select the operand size of the bus cycle for the channel B break condition.
				00: The break condition does not include operand size
				01: The break condition is byte access
				10: The break condition is word access
	et4U.com			11: The break condition is longword access

### 25.2.9 Break Control Register (BRCR)

BRCR sets the following conditions:

- 1. Channels A and B are used in two independent channel conditions or under the sequential condition.
- 2. A break is set before or after instruction execution.
- 3. Specify whether to include the number of execution times on channel B in comparison conditions.
- 4. Determine whether to include data bus on channel B in comparison conditions.
- 5. Enable PC trace.

BRCR is a 32-bit readable/writable register that has break conditions match flags and bits for setting a variety of break conditions.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
15	SCMFCA	0	R/W	L Bus Cycle Condition Match Flag A
				When the L bus cycle condition in the break conditions set for channel A is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 into this bit.
				0: The L bus cycle condition for channel A does not match
				1: The L bus cycle condition for channel A matches
14	SCMFCB	0	R/W	L Bus Cycle Condition Match Flag B
				When the L bus cycle condition in the break conditions set for channel B is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 into this bit.
taSheet4U				0: The L bus cycle condition for channel B does not match
				1: The L bus cycle condition for channel B matches
13	SCMFDA	0	R/W	I Bus Cycle Condition Match Flag A
				When the I bus cycle condition in the break conditions set for channel A is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 into this bit.
				0: The I bus cycle condition for channel A does not match
				1: The I bus cycle condition for channel A matches
12	SCMFDB	0	R/W	I Bus Cycle Condition Match Flag B
				When the I bus cycle condition in the break conditions set for channel B is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 into this bit.
				0: The I bus cycle condition for channel B does not match
				1: The I bus cycle condition for channel B matches
11	PCTE	0	R/W	PC Trace Enable
				0: Disables PC trace
				1: Enables PC trace
10	PCBA	0	R/W	PC Break Select A
				Selects the break timing of the instruction fetch cycle for channel A as before or after instruction execution.
				0: PC break of channel A is set before instruction execution
				1: PC break of channel A is set after instruction execution

Bit	Bit Name	Initial Value	R/W	Description
9, 8	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
7	DBEB	0	R/W	Data Break Enable B
				Selects whether or not the data bus condition is included in the break condition of channel B.
				0: No data bus condition is included in the condition of channel B
				The data bus condition is included in the condition of channel B
6	PCBB	0	R/W	PC Break Select B
				Selects the break timing of the instruction fetch cycle for channel B as before or after instruction execution.
ıtaSheet4				0: PC break of channel B is set before instruction execution
				1: PC break of channel B is set after instruction execution
5, 4	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
3	SEQ	0	R/W	Sequence Condition Select
				Selects two conditions of channels A and B as independent or sequential conditions.
				Channels A and B are compared under independent conditions
				Channels A and B are compared under sequential conditions (channel A, then channel B)
2, 1	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
0	ETBE	0	R/W	Number of Execution Times Break Enable
				Enables the execution-times break condition only on channel B. If this bit is 1 (break enable), a user break is issued when the number of break conditions matches with the number of execution times that is specified by BETR.
				The execution-times break condition is disabled on channel B
				The execution-times break condition is enabled on channel B     www.DataSheet4U.com

## 25.2.10 Execution Times Break Register (BETR)

BETR is a 16-bit readable/writable register. When the execution-times break condition of channel B is enabled, this register specifies the number of execution times to make the break. The maximum number is  $2^{12} - 1$  times. When a break condition is satisfied, it decreases BETR. A break is issued when the break condition is satisfied after BETR becomes H'0001.

		Initial		
Bit	Bit Name	Value	R/W	Description
15 to 12	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0. If 1 is written to these bits, correct operation cannot be guaranteed.
11 to 0	BET11 to BET0	All 0	R/W	Number of Execution Times

Note: If the break condition of channel B is a break condition of instruction fetch cycle and the break instructions correspond to the following instructions, the BETR is not decremented by www.DataSheel41 every time when a break is occurred. Refer to the following for the decremented value.

### www.Da25.2.11 U.Branch Source Register (BRSR)

BRSR is a 32-bit read-only register. BRSR stores bits 27 to 0 in the address of the branch source instruction. BRSR has the flag bit that is set to 1 when a branch occurs. This flag bit is cleared to 0 when BRSR is read, the setting to enable PC trace is made, or BRSR is initialized by a power-on reset. Other bits are not initialized by a power-on reset. The eight BRSR registers have a queue structure and a stored register is shifted at every branch.

D:4	Dit Name	Initial	D AA	Description
Bit	Bit Name	Value	R/W	Description
31	SVF	0	R	BRSR Valid Flag
				Indicates whether the branch source address is stored. When a branch source address is fetched, this flag is set to 1. This flag is cleared to 0 by reading from BRSR.
				0: The value of BRSR register is invalid
				1: The value of BRSR register is valid
30 to 28	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0.
27 to 0	BSA27 to BSA0	_	R	Branch Source Address
				Store bits 27 to 0 of the branch source address.

### 25.2.12 Branch Destination Register (BRDR)

BRDR is a 32-bit read-only register. BRDR stores bits 27 to 0 in the address of the branch destination instruction. BRDR has the flag bit that is set to 1 when a branch occurs. This flag bit is cleared to 0 when BRDR is read, the setting to enable PC trace is made, or BRDR is initialized by a power-on reset. Other bits are not initialized by a power-on reset. The eight BRDR registers have a queue structure and a stored register is shifted at every branch.

Bit	Bit Name	Initial Value	R/W	Description
31	DVF	0	R	BRDR Valid Flag
				Indicates whether a branch destination address is stored. When a branch destination address is fetched, this flag is set to 1. This flag is cleared to 0 by reading BRDR.
				0: The value of BRDR register is invalid
				1: The value of BRDR register is valid
30 to 28	_	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0.
27 to 0	BDA27 to BDA0	) —	R	Branch Destination Address
				Store bits 27 to 0 of the branch destination address.

## 25.3 Operation

### 25.3.1 Flow of the User Break Operation

The flow from setting of break conditions to user break exception processing is described below:

- 1. The break addresses are set in the break address registers (BARA or BARB). The masked addresses are set in the break address mask registers (BAMRA or BAMRB). The break data is set in the break data register (BDRB). The masked data is set in the break data mask register (BDMRB). The bus break conditions are set in the break bus cycle registers (BBRA or BBRB). Three groups of BBRA or BBRB (L bus cycle/I bus cycle select, instruction fetch/data access select, and read/write select) are each set. No user break will be generated if even one of these groups is set with 00. The respective conditions are set in the bits of the break control register (BRCR). Make sure to set all registers related to breaks before setting BBRA or BBRB.
- 2. When the break conditions are satisfied, the UBC sends a user break request to the CPU and www.DataStreets the L bus condition match flag (SCMFCA or SCMFCB) and the I bus condition match flag (SCMFDA or SCMFDB) for the appropriate channel. When the X/Y memory bus is specified for channel B, SCMFCB is used for the condition match flag.
  - 3. The appropriate condition match flags (SCMFCA, SCMFDA, SCMFCB, and SCMFDB) can be used to check if the set conditions match or not. The matching of the conditions sets flags, but they are not reset. 0 must first be written to them before they can be used again.
  - 4. There is a chance that the break set in channel A and the break set in channel B occur around the same time. In this case, there will be only one break request to the CPU, but these two break channel match flags could be both set.
  - 5. When selecting the I bus as the break condition, note the following:
    - Several bus masters, including the CPU and DMAC, are connected to the I bus. The UBC monitors bus cycles generated by all bus masters, and determines the condition match.
    - Physical addresses are used for the I bus. Set a physical address in break address registers (BARA and BARB). The bus cycles for logical addresses issued on the L bus by the CPU are converted to physical addresses before being output to the I bus. (If the address translation function is enabled, address translation by the MMU is carried out.)
    - For data access cycles issued on the L bus by the CPU, if their logical addresses are not to be cached, they are issued with the data size specified on the L bus and their addresses are not rounded.
    - For instruction fetch cycles issued on the L bus by the CPU, even though their logical addresses are not to be cached, they are issued in longwords and their addresses are rounded to match longword boundaries.

- If a logical address issued on the L bus by the CPU is an address to be cached and a cache miss occurs, its bus cycle is issued as a cache fill cycle on the I bus. In this case, it is issued in longwords and its address is rounded to match longword boundaries. However note that cache fill is not performed for a write miss in write through mode. In this case, the bus cycle is issued with the data size specified on the L bus and its address is not rounded. In write back mode, a write back cycle may be issued in addition to a read fill cycle. It is a longword bus cycle whose address is rounded to match longword boundaries.
- I bus cycles (including read fill cycles) resulting from instruction fetches on the L bus by the CPU are defined as instruction fetch cycles on the I bus, while other bus cycles are defined as data access cycles.
- The DMAC only issues data access cycles for I bus cycles.
- If a break condition is specified for the I bus, even when the condition matches in an I bus cycle resulting from an instruction executed by the CPU, at which instruction the break is to be accepted cannot be clearly defined.
- 6. While the block bit (BL) in the CPU status register (SR) is set to 1, no breaks can be accepted. However, condition determination will be carried out, and if the condition matches, the www.Data corresponding condition match flag is set to 1.

### 25.3.2 Break on Instruction Fetch Cycle

- 1. When L bus/instruction fetch/read/word or longword is set in the break bus cycle register (BBRA or BBRB), the break condition becomes the L bus instruction fetch cycle. Whether it breaks before or after the execution of the instruction can then be selected with the PCBA or PCBB bit of the break control register (BRCR) for the appropriate channel. If an instruction fetch cycle is set as a break condition, clear LSB in the break address register (BARA or BARB) to 0. A break cannot be generated as long as this bit is set to 1.
- 2. An instruction set for a break before execution breaks when it is confirmed that the instruction has been fetched and will be executed. This means this feature cannot be used on instructions fetched by overrun (instructions fetched at a branch or during an interrupt transition, but not to be executed). When this kind of break is set for the delay slot of a delayed branch instruction, the break is generated prior to execution of the delayed branch instruction.

Note: If a branch does not occur at a delay condition branch instruction, the subsequent instruction is not recognized as a delay slot.

- 3. When the condition is specified to be occurred after execution, the instruction set with the break condition is executed and then the break is generated prior to the execution of the next instruction. As with pre-execution breaks, this cannot be used with overrun fetch instructions. When this kind of break is set for a delayed branch instruction and its delay slot, a break is not generated until the first instruction at the branch destination.
- 4. When an instruction fetch cycle is set for channel B, the break data register B (BDRB) is ignored. Therefore, break data cannot be set for the break of the instruction fetch cycle.

5. If the I bus is set for a break of an instruction fetch cycle, the condition is determined for the instruction fetch cycles on the I bus. For details, see 5 in section 25.3.1, Flow of the User Break Operation.

### 25.3.3 Break on Data Access Cycle

- 1. If the L bus is specified as a break condition for data access break, condition comparison is performed for the logical addresses (and data) accessed by the executed instructions, and a break occurs if the condition is satisfied. If the I bus is specified as a break condition, condition comparison is performed for the physical addresses (and data) of the data access cycles that are issued on the I bus by all bus masters including the CPU, and a break occurs if the condition is satisfied. For details on the CPU bus cycles issued on the I bus, see 5 in section 25.3.1, Flow of the User Break Operation.
- 2. The relationship between the data access cycle address and the comparison condition for each operand size is listed in table 25.3.

Table 25.3 Data Access Cycle Addresses and Operand Size Comparison Conditions

Access Size	Address Compared
Longword	Compares break address register bits 31 to 2 to address bus bits 31 to 2
Word	Compares break address register bits 31 to 1 to address bus bits 31 to 1
Byte	Compares break address register bits 31 to 0 to address bus bits 31 to 0

This means that when address H'00001003 is set in the break address register (BARA or BARB), for example, the bus cycle in which the break condition is satisfied is as follows (where other conditions are met).

Longword access at H'00001000

Word access at H'00001002

Byte access at H'00001003

3. When the data value is included in the break conditions on channel B:

When the data value is included in the break conditions, either longword, word, or byte is specified as the operand size of the break bus cycle register B (BBRB). When data values are included in break conditions, a break is generated when the address conditions and data conditions both match. To specify byte data for this case, set the same data in two bytes at bits 15 to 8 and bits 7 to 0 of the break data register B (BDRB) and break data mask register B (BDMRB). When word or byte is set, bits 31 to 16 of BDRB and BDMRB are ignored. Set the word data in bits 31 to 16 in BDRB and BDMRB when including the value of the data bus as a break condition for the MOVS.W @-As,Ds, MOVS.W @As+,Ds, or MOVS.W @As+Ix,Ds instruction (bits 15 to 0 are ignored).

- 4. Access by a PREF instruction is handled as read access in longword units without access data. Therefore, if including the value of the data bus when a PREF instruction is specified as a break condition, a break will not occur.
- 5. If the L bus is selected, a break occurs on ending execution of the instruction that matches the break condition, and immediately before the next instruction is executed. However, when data is also specified as the break condition, the break may occur on ending execution of the instruction following the instruction that matches the break condition. If the I bus is selected, the instruction at which the break will occur cannot be determined. When this kind of break occurs at a delayed branch instruction or its delay slot, the break may not actually take place until the first instruction at the branch destination.

### 25.3.4 Break on X/Y-Memory Bus Cycle

- 1. The break condition on an X/Y-memory bus cycle is specified only in channel B. If the XYE bit in BBRB is set to 1, the break address and break data on X/Y-memory bus are selected. At this time, select the X-memory bus or Y-memory bus by specifying the XYS bit in BBRB. The ata-break condition cannot include both X-memory and Y-memory at the same time. The break condition is applied to an X/Y-memory bus cycle by specifying L bus/data access cycle/read or write/word or no specified operand size (in bits 7 to 0) in the break bus cycle register B (BBRB).
- 2. When an X-memory address is selected as the break condition, specify an X-memory address in the upper 16 bits in BARB and BAMRB. When a Y-memory address is selected, specify a Y-memory address in the lower 16 bits. Specification of X/Y-memory data is the same for BDRB and BDMRB.
- 3. The timing of a data access break for the X memory or Y memory bus to occur is the same as a data access break of the L bus. For details, see 5 in section 25.3.3, Break on Data Access Cycle.

### 25.3.5 Sequential Break

- By setting the SEQ bit in BRCR to 1, the sequential break is issued when a channel B break
  condition matches after a channel A break condition matches. A user break is not generated
  even if a channel B break condition matches before a channel A break condition matches.
  When channels A and B conditions match at the same time, the sequential break is not issued.
  To clear the channel A condition match when a channel A condition match has occurred but a
  channel B condition match has not yet occurred in a sequential break specification, clear the
  SEO bit in BRCR to 0.
- 2. In sequential break specification, the L/I/X/Y bus can be selected and the execution times break condition can be also specified. For example, when the execution times break condition is specified, the break condition is satisfied when a channel B condition matches with BETR = H'0001 after a channel A condition has matched.

#### 25.3.6 Value of Saved Program Counter

When a break occurs, the address of the instruction from where execution is to be resumed is saved in the SPC, and the exception handling state is entered. If the L bus is specified as a break condition, the instruction at which the break should occur can be clearly determined (except for when data is included in the break condition). If the I bus is specified as a break condition, the instruction at which the break should occur cannot be clearly determined.

- When instruction fetch (before instruction execution) is specified as a break condition:
   The address of the instruction that matched the break condition is saved in the SPC. The instruction that matched the condition is not executed, and the break occurs before it. However when a delay slot instruction matches the condition, the address of the delayed branch instruction is saved in the SPC.
- 2. When instruction fetch (after instruction execution) is specified as a break condition:

  The address of the instruction following the instruction that matched the break condition is saved in the SPC. The instruction that matches the condition is executed, and the break occurs before the next instruction is executed. However when a delayed branch instruction or delay slot matches the condition, these instructions are executed, and the branch destination address is saved in the SPC.
- 3. When data access (address only) is specified as a break condition: The address of the instruction immediately after the instruction that matched the break condition is saved in the SPC. The instruction that matches the condition is executed, and the break occurs before the next instruction is executed. However when a delay slot instruction matches the condition, the branch destination address is saved in the SPC.
- 4. When data access (address + data) is specified as a break condition:
  - When a data value is added to the break conditions, the address of an instruction that is within two instructions of the instruction that matched the break condition is saved in the SPC. At which instruction the break occurs cannot be determined accurately.
  - When a delay slot instruction matches the condition, the branch destination address is saved in the SPC. If the instruction following the instruction that matches the break condition is a branch instruction, the break may occur after the branch instruction or delay slot has finished. In this case, the branch destination address is saved in the SPC.

#### 25.3.7 PC Trace

- 1. Setting PCTE in BRCR to 1 enables PC traces. When branch (branch instruction, and interrupt exception) is generated, the branch source address and branch destination address are stored in BRSR and BRDR, respectively.
- 2. The values stored in BRSR and BRDR are as given below due to the kind of branch.
  - If a branch occurs due to a branch instruction, the address of the branch instruction is saved in BRSR and the address of the branch destination instruction is saved in BRDR.
  - If a branch occurs due to an interrupt or exception, the value saved in SPC due to exception occurrence is saved in BRSR and the start address of the exception handling routine is saved in BRDR.

When a repeat loop of the DSP extended function is used, control being transferred from the repeat end instruction to the repeat start instruction is not recognized as a branch, and the values are not stored in BRSR and BRDR.

3. BRSR and BRDR have eight pairs of queue structures. The top of queues is read first when the address stored in the PC trace register is read. BRSR and BRDR share the read pointer. Read BRSR and BRDR in order, the queue only shifts after BRDR is read. After switching the PCTE bit (in BRCR) off and on, the values in the queues are invalid.

#### 25.3.8 Usage Examples

### Break Condition Specified for L Bus Instruction Fetch Cycle:

(Example 1-1)

Register specifications

BARA = H'00000404, BAMRA = H'00000000, BBRA = H'0054, BARB = H'00008010, BAMRB = H'00000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300400

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'00000404, Address mask: H'00000000

Bus cycle: L bus/instruction fetch (after instruction execution)/read (operand size is not

included in the condition)

- Channel B

Address: H'00008010, Address mask: H'00000006

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read (operand size is

not included in the condition)

A user break occurs after an instruction of address H'00000404 is executed or before instructions of addresses H'00008010 to H'00008016 are executed.

#### (Example 1-2)

• Register specifications

BARA = H'00037226, BAMRA = H'00000000, BBRA = H'0056, BARB = H'0003722E, BAMRB = H'00000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000008

Specified conditions: Channel A/channel B sequential mode

- Channel A

Address: H'00037226, Address mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read/word

- Channel B

Address: H'0003722E, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read/word

After an instruction with address H'00037226 is executed, a user break occurs before an instruction with address H'0003722E is executed.

#### (Example 1-3)

• Register specifications

BARA = H'00027128, BAMRA = H'00000000, BBRA = H'005A, BARB = H'00031415, BAMRB = H'00000000, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300000

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'00027128, Address mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/write/word

- Channel B

Address: H'00031415, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read (operand size is

not included in the condition)

On channel A, no user break occurs since instruction fetch is not a write cycle. On channel B, no user break occurs since instruction fetch is performed for an even address.

#### (Example 1-4)

#### Register specifications

BARA = H'00037226, BAMRA = H'00000000, BBRA = H'005A, BARB = H'0003722E, BAMRB = H'00000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'000000008

Specified conditions: Channel A/channel B sequential mode

#### — Channel A

Address: H'00037226, Address mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/write/word

#### - Channel B

Address: H'0003722E, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read/word

Since instruction fetch is not a write cycle on channel A, a sequential condition does not match. Therefore, no user break occurs.

#### (Example 1-5)

#### • Register specifications

BARA = H'00000500, BAMRA = H'00000000, BBRA = H'0057, BARB = H'00001000, BAMRB = H'00000000, BBRB = H'0057, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300001, BETR = H'0005

Specified conditions: Channel A/channel B independent mode

#### — Channel A

Address: H'00000500, Address mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read/longword

#### - Channel B

Address: H'00001000, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read/longword

The number of execution-times break enable (5 times)

On channel A, a user break occurs before an instruction of address H'00000500 is executed. On channel B, a user break occurs after the instruction of address H'00001000 are executed four times and before the fifth time.

#### (Example 1-6)

• Register specifications

BARA = H'00008404, BAMRA = H'00000FFF, BBRA = H'0054, BARB = H'00008010, BAMRB = H'00000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000400

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'00008404, Address mask: H'00000FFF

Bus cycle: L bus/instruction fetch (after instruction execution)/read (operand size is not

included in the condition)

— Channel B

Address: H'00008010, Address mask: H'00000006

Data: H'00000000, Data mask: H'00000000

Bus cycle: L bus/instruction fetch (before instruction execution)/read (operand size is

not included in the condition)

A user break occurs after an instruction with addresses H'00008000 to H'00008FFE is executed or before an instruction with addresses H'00008010 to H'00008016 are executed.

### **Break Condition Specified for L Bus Data Access Cycle:**

(Example 2-1)

Register specifications

BARA = H'00123456, BAMRA = H'00000000, BBRA = H'0064, BARB = H'000ABCDE, BAMRB = H'000000FF, BBRB = H'006A, BDRB = H'0000A512, BDMRB = H'00000000, BRCR = H'00000080

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'00123456, Address mask: H'00000000

Bus cycle: L bus/data access/read (operand size is not included in the condition)

— Channel B

Address: H'000ABCDE, Address mask: H'000000FF

Data: H'0000A512, Data mask: H'00000000

Bus cycle: L bus/data access/write/word

On channel A, a user break occurs with longword read from address H'00123454, word read from address H'00123456, or byte read from address H'00123456. On channel B, a user break occurs when word H'A512 is written in addresses H'000ABC00 to H'000ABCFE.

(Example 2-2)

Register specifications

BARA = H'01000000, BAMRA = H'00000000, BBRA = H'0066, BARB = H'0000F000, BAMRB = H'FFFF0000, BBRB = H'036A, BDRB = H'00004567, BDMRB = H'00000000, BRCR = H'00300080

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'01000000, Address mask: H'00000000

Bus cycle: L bus/data access/read/word

- Channel B

Y Address: H'0000F000, Address mask: H'FFFF0000

Data: H'00004567, Data mask: H'00000000

Bus cycle: Y bus/data access/write/word

On channel A, a user break occurs during word read from address H'01000000 in the memory space. On channel B, a user break occurs when word data H'4567 is written in address H'0000F000 in the Y memory space. The X/Y-memory space is changed by a mode setting.

### **Break Condition Specified for I Bus Data Access Cycle:**

(Example 3-1)

Register specifications

BARA = H'00314156, BAMRA = H'00000000, BBRA = H'0094, BARB = H'00055555, BAMRB = H'00000000, BBRB = H'00A9, BDRB = H'00007878, BDMRB = H'00000F0F, BRCR = H'00000080

Specified conditions: Channel A/channel B independent mode

— Channel A

Address: H'00314156, Address mask: H'00000000

Bus cycle: I bus/instruction fetch/read (operand size is not included in the condition)

- Channel B

Address: H'00055555, Address mask: H'00000000

Data: H'00000078, Data mask: H'0000000F

Bus cycle: I bus/data access/write/byte

On channel A, a user break occurs when instruction fetch is performed for address H'00314156 in the memory space.

On channel B, a user break occurs when the I bus writes byte data H'7 in address H'00055555.

### 25.4 Usage Notes

- The CPU can read from or write to the UBC registers via the I bus. Accordingly, during the
  period from executing an instruction to rewrite the UBC register till the new value is actually
  rewritten, the desired break may not occur. In order to know the timing when the UBC register
  is changed, read from the last written register. Instructions after then are valid for the newly
  written register value.
- 2. UBC cannot monitor access to the L bus and I bus in the same channel.
- 3. Note on specification of sequential break:

A condition match occurs when a B-channel match occurs in a bus cycle after an A-channel match occurs in another bus cycle in sequential break setting. Therefore, no break occurs even if a bus cycle, in which an A-channel match and a channel B match occur simultaneously, is set.

- 4. When a user break and another exception occur at the same instruction, which has higher priority is determined according to the priority levels defined in table 4.1 in section 4, Exception Handling. If an exception with higher priority occurs, the user break is not www.DataStgenerated.
  - Pre-execution break has the highest priority.
  - When a post-execution break or data access break occurs simultaneously with a re-execution-type exception (including pre-execution break) that has higher priority, the re-execution-type exception is accepted, and the condition match flag is not set (see the exception in the following note). The break will occur and the condition match flag will be set only after the exception source of the re-execution-type exception has been cleared by the exception handling routine and re-execution of the same instruction has ended.
  - When a post-execution break or data access break occurs simultaneously with a completion-type exception (TRAPA) that has higher priority, though a break does not occur, the condition match flag is set.
  - 5. Note the following exception for the above note.

If a post-execution break or data access break is satisfied by an instruction that generates a CPU address error by data access, the CPU address error is given priority to the break. Note that the UBC condition match flag is set in this case.

- 6. Note the following when a break occurs in a delay slot.
  - If a pre-execution break is set at the delay slot instruction of the RTE instruction, the break does not occur until the branch destination of the RTE instruction.
- 7. User breaks are disabled during UBC module standby mode. Do not read from or write to the UBC registers during UBC module standby mode; the values are not guaranteed.
- 8. When the repeat loop of the DSP extended function is used, even though a break condition is satisfied during execution of the entire repeat loop or several instructions in the repeat loop, the break may be held. For details, see section 4, Exception Handling.

# Section 26 User Debugging Interface (H-UDI)

This LSI incorporates a user debugging interface (H-UDI) and advanced user debugger (AUD) for a boundary scan function and emulator support.

This section summarizes the boundary scan function for the H-UDI. For details on the JTAG function incorporated in this LSI, refer to the material separately handed, BSDL (Boundary-Scan Description Language). For details on the emulator functions such as the AUD, refer to the user's manual of each emulator.

#### 26.1 Features

The H-UDI is a serial I/O interface that conforms to JTAG (Joint Test Action Group, IEEE Standard 1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture) specifications.

DaThe H-UDI in this LSI supports a boundary scan mode, and is also used for emulator connection.

When using an emulator, H-UDI functions should not be used. When using the boundary scan function for the H-UDI, the  $\overline{ASEMD0}$  pin should be fixed to high level. For the method of connecting the emulator, refer to the emulator's user's manual.

Figure 26.1 shows a block diagram of the H-UDI.

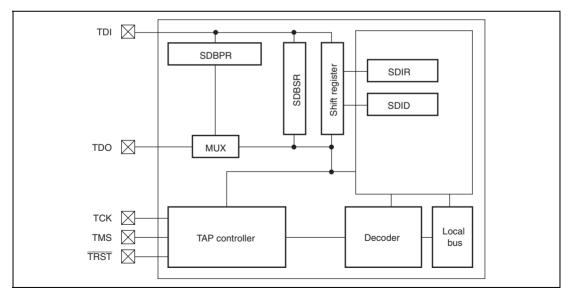

Figure 26.1 Block Diagram of H-UDI

# 26.2 Input/Output Pins

Table 26.1 shows the pin configuration of the H-UDI.

**Table 26.1 Pin Configuration** 

Pin Name	I/O	Description
TCK	Input	Serial Data Input/Output Clock Pin
		Data is serially supplied to the H-UDI from the data input pin (TDI), and output from the data output pin (TDO), in synchronization with this clock.
TMS	Input	Mode Select Input Pin
		The state of the TAP control circuit is determined by changing this signal in synchronization with TCK. The protocol conforms to the JTAG standard (IEEE Std.1149.1).
TRST	Input	Reset Input Pin
ataSheet4U.com		Input is accepted asynchronously with respect to TCK, and when low, the H-UDI is reset. TRST must be low for a constant period when power is turned on regardless of using the H-UDI function. This is different from the JTAG standard. See section 26.4.2, Reset Configuration, for more information.
TDI	Input	Serial Data Input Pin
		Data transfer to the H-UDI is executed by changing this signal in synchronization with TCK.
TDO	Output	Serial Data Output Pin
		Data read from the H-UDI is executed by reading this pin in synchronization with TCK. The data output timing depends on the command type set in the SDIR. See section 26.3.2 Instruction Register (SDIR), for more information.
ASEMD0	Input	ASE Mode Select Pin
		If a low level is input at the $\overline{\text{ASEMD0}}$ pin while the $\overline{\text{RESETP}}$ pin is asserted, ASE mode is entered; if a high level is input, normal mode is entered and the JTAG function can be used. In ASE mode, the dedicated emulator function can be used. The input to the $\overline{\text{ASEMD0}}$ pin should be fixed to either high or low level.
ASEBRKAK, AUDSYNC, AUDATA3 to AUDATA0, AUDCK	Output	Dedicated Emulator Pin

Note: The ASEMDO pin should be fixed to high level when using the boundary scan function.

### **26.3** Register Descriptions

The H-UDI has the following registers. For details on register addresses and register states in each processing state, see section 27, List of Registers\*.

- Bypass register (SDBPR)
- Instruction register (SDIR)
- Boundary scan register (SDBSR)
- ID register (SDID)

Note: \* The H-UDI registers can be accessed from the CPU only when the emulator function is enabled in ASE mode. These registers function as part of the dedicated circuit for the JTAG function in normal mode (mode in which boundary scan function is used).

Therefore, these registers should not be accessed from the CPU in normal mode.

#### 26.3.1 Bypass Register (SDBPR)

SDBPR is a 1-bit register that can be accessed only via the H-UDI pin. This register cannot be accessed from the CPU. When SDIR is set to bypass mode, SDBPR is connected between H-UDI pins TDI and TDO. The initial value is undefined.

## 26.3.2 Instruction Register (SDIR)

SDIR is a 3-bit register in normal mode. This register can be written only via the H-UDI pin. This register cannot be accessed from the CPU. Undefined value is read even when this register is accessed from the CPU using the address which is listed in section 27, List of Registers. JTAG IDCODE is set in SDIR as the initial value. Operation is not guaranteed if a reserved command is set in SDIR.

In ASE mode, SDIR is a 16-bit read-only register read from the CPU. The JTAG function is disabled. For details on the function of SDIR in ASE mode, refer to the emulator's user's manual.

Bit	Bit Name	Initial Value	R/W	Description
2	TI2	1	_	Test Instruction 2 to 0
1	TI1	0		The JTAG instruction is transferred to SDIR by a serial
0	TIO	0	_	input from TDI. Cannot be accessed from the CPU for either read or write.
				For the commands, see table 26.2.

Table 26.2 JTAG Commands

Bits 2 to 0

TI2	TI1	TI0	Description	
0	0	0	JTAG EXTEST	
0	0	1	JTAG SAMPLE/PREL	OAD
0	1	0	Reserved	
0	1	1	Reserved	
1	0	0	JTAG IDCODE	(Initial value)
1	0	1	Reserved	
1	1	0	Reserved	
1	1	1	JTAG BYPASS	

#### 26.3.3 Boundary Scan Register (SDBSR)

DataSheet4U.com

SDBSR is a shift register, located on the PAD, for controlling the input/output pins of this LSI. The initial value is undefined, and this register cannot be accessed from the CPU.

Using the EXTEST and SAMPLE/PRELOAD commands, a boundary scan test conforming to the JTAG standard can be carried out. Table 26.3 gives the correspondence between the pins of the SH7660 and boundary scan register.

Table 26.3 Correspondence between Pins of SH7660 and Boundary Scan Register

## 26.3.4 ID Register (SDID)

SDID is a 32-bit register that consists of the version, parts number, manufacturer, and fixed code. SDID can be read from the CPU even in normal mode as two 16-bit registers, SDIDH and SDIDL. However, SDID cannot be written to.

SDID cannot be accessed from the H-UDI pin.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DID31 to DID0		R	Device ID31 to ID0
		description		Device ID register that is stipulated by JTAG. H'0028200F (initial value) for this LSI. The upper four bits may be changed by the chip version.
				SDIDH corresponds to bits 31 to 16.
				SDIDL corresponds to bits 15 to 0.

www.DataSheet4II.com

# 26.4 Operation

#### 26.4.1 TAP Controller

Figure 26.2 shows the internal states of the TAP controller. State transitions basically conform to the JTAG standard.

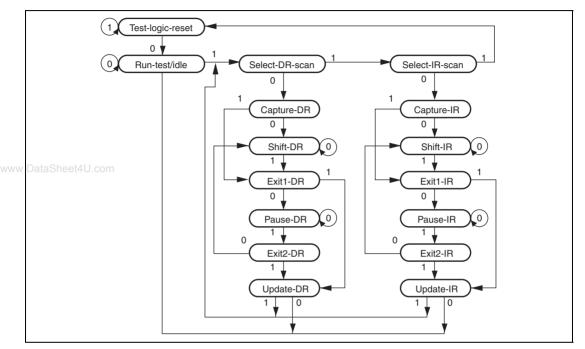

Figure 26.2 TAP Controller State Transitions

#### 26.4.2 Reset Configuration

Table 26.4 lists the reset configuration of this LSI.

**Table 26.4 Reset Configuration** 

ASEMD0*1	RESETP	TRST	Chip State	
Н	L	L	Normal reset and H-UDI reset	
		Н	Normal reset	
	Н	L	H-UDI reset only	
		Н	Normal operation	
L	L	L	Reset hold*2	
		Н	Normal reset	
	Н	L	H-UDI reset only	
		Н	Normal operation	

DaNotes: 41. Performs normal mode or ASE mode settings

ASEMD0 = H. normal mode

ASEMD0 = L. ASE mode

- 2. In ASE mode, reset hold is enabled by driving the RESETP and TRST pins low for a constant cycle. In this state, the CPU does not start up, even if RESETP is driven high. When TRST is driven high, H-UDI operation is enabled, but the CPU does not start up. The reset hold state is cancelled by the following:
  - Another RESETP assert (power-on reset)
  - TRST reassert

## 26.4.3 TDO Output Timing

The timing for switching data output from the TDO in normal mode changes at the TCK falling edge. This is a timing defined by the JTAG standard. This timing for switching data output from the TDO varies if the emulator function is used in ASE mode. For details on the timing, refer to the emulator's user's manual.

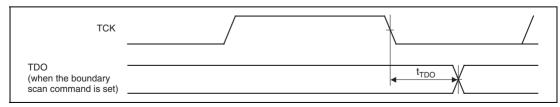

Figure 26.3 H-UDI Data Transfer Timing

## 26.5 Boundary Scan

When ASEMD0 is driven high, the H-UDI pins are function as pins for the JTAG. All boundary scan cells on this LSI are connected as a single shift register with an input from the TDI pin and an output from the TDO pin to form the boundary scan register (SDBSR). The TDO and TDI pins of all LSIs that support the boundary scan function on the board are connected as a single shift register to form the boundary scan register. This allows wiring between the LSIs on the board and the mounted conditions of LSIs to be tested.

#### **26.5.1** Supported Instructions

This LSI supports the three essential instructions defined in the JTAG standard (BYPASS, SAMPLE/PRELOAD, and EXTEST) and an optional instruction (IDCODE).

#### 1. BYPASS

The BYPASS instruction is an essential standard instruction that operates the bypass register.

This instruction shortens the shift path to speed up serial data transfer involving other LSIs on the printed circuit board. This LSI's system circuits are not affected by execution of this instruction. The instruction code is B'111.

#### 2. SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction inputs values from this LSI's internal circuitry to the boundary scan register, outputs values from the scan path, and loads data onto the scan path. When this instruction is executing, this LSI's input pin signals are transmitted directly to the internal circuitry, and internal circuit values are directly output externally from the output pins. This LSI's system circuits are not affected by execution of this instruction. The instruction code is B'001.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuitry, or a value to be transferred from the internal circuitry to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching is performed in synchronization with the rising of TCK in the Capture-DR state. Snapshot latching does not affect normal operation of this LSI.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

#### 3. EXTEST

This instruction is provided to test external circuitry when this LSI is mounted on a printed circuit board. When this instruction is executed, output pins are used to output test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed circuit board, and input pins are used to latch test results into the boundary scan register from the printed circuit board. If testing is carried out by using the EXTEST instruction N times, the Nth test data is scanned-in when test data (N-1) is scanned out.

Data loaded into the output pin boundary scan register in the Capture-DR state is not used for external circuit testing (it is replaced by a shift operation).

The instruction code is B'000.

#### 4. IDCODE

The H-UDI pins can be entered in IDCODE mode which is defined by the JTAG by setting the command to SDIR from the H-UDI pins. When the H-UDI is initialized (when the TRST pin is asserted or the TAP controller is transited to the Test-Logic-Reset state), IDCODE mode is entered.

The instruction code is B'100.

ww.DataSheet4U.com

#### **26.5.2** Cautions

- Boundary scan mode does not cover clock-related signals: EXTAL2, XTAL2, EXTAL, XTAL.
- 2. Boundary scan mode does not cover the reset-related signal:  $\overline{\text{RESETP}}$ .
- 3. Boundary scan mode does not cover H-UDI-related signals: TCK, TDI, TDO, TMS, TRST, ASEMDO.
- 4. Boundary scan mode does not cover some Bluetooth (BT) related signals: RDI\_TXTRDATA, RDI\_RXBDW\_OUT, RDI\_REFCLK\_IN, RDI\_CTRL3, RDI\_CTRL4, RFSEL, RCI\_SPI\_TXRX, RCI\_SPI\_CLK, RCI\_SPI\_ENB, RREF.
- 5. Boundary scan mode does not cover the test-related signal: TEST REG, TEST.
- 6. Boundary scan mode does not cover analog signals: USB\_P, USB\_N, DA0, DA1.
- 7. When the EXTEST command is set, fix the RESETP pin low.
- 8. While boundary scan is being executed, fix the ASEMDO pin high.

## 26.6 Usage Notes

- 1. An H-UDI command, once set, will not be modified as long as another command is not reissued from the H-UDI. If the same command is given continuously, the command must be set after a command (BYPASS, etc.) that does not affect chip operations is once set.
- 2. Because chip operations are suspended in standby mode, H-UDI commands are not accepted. To maintain the TAP controller state before and after standby mode, TCK must be kept high during the transition to standby mode.
- 3. The H-UDI is used for emulator connection. Therefore, H-UDI functions cannot be used when using an emulator.
- 4. Usage of the TRST pin as a boundary scan function is optional. In this LSI, the TAP controller must be initialized simultaneously by the TRST pin at a power-on reset. Note however that in other LSIs, a power-on reset function may be available instead of the TRST pin or initialization of the TAP controller at a power-on reset may not be required. Take the following points in consideration when applying a power-on reset signal to the TRST pin.
  - A reset signal must always be applied when the power is turned on.
  - The power-on reset circuit must be separated from the LSI so that the TRST signal of the board tester does not affect the LSI operation. Resetting the TAP controller during board testing may generate a TRST signal asynchronously. If the power-on reset circuit is not separated in this case, the generated TRST signal will likely affect LSI operation during board testing (e.g. system reset occurs asynchronously).
  - Due to the opposite reason as described above, the power-on reset circuit must be separated from the LSI so that the LSI's system reset does not affect the TRST signal of the board tester. During board testing, the board tester controls the system reset signal via the boundary scans to examine the connection of the LSI system reset signal. If the power-on reset circuit is not separated in this case, the above operation resets the TAP controller, and testing may not be performed correctly.

Figure 26.4 shows an example of circuit connection.

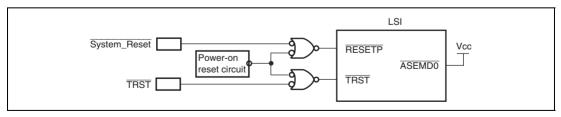

Figure 26.4 Example of Connecting Reset Signals without Mutual Interference

# Section 27 List of Registers

The address map gives information on the on-chip I/O registers and is configured as described below

- 1. Register Addresses (by functional module, in order of the corresponding section numbers)
  - Descriptions by functional module, in order of the corresponding section numbers
  - Access to reserved addresses which are not described in this list is disabled.
  - When registers consist of 16 or 32 bits, the addresses of the MSBs are given, on the presumption of a big-endian system.

#### 2. Register Bits

- Bit configurations of the registers are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
- Reserved bits are indicated by in the bit name.
- No entry in the bit-name column indicates that the whole register is allocated as a counter www.DataSheet or for holding data.
  - When registers consist of 16 or 32 bits, bits are described from the MSB side.
     The order in which bytes are described is on the presumption of a big-endian system
  - 3. Register States in Each Operating Mode
    - Register states are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
    - For the initial state of each bit, refer to the description of the register in the corresponding section.
    - The register states described are for the basic operating modes. If there is a specific reset for an on-chip module, refer to the section on that on-chip module.

# 27.1 Register Addresses (by functional module, in order of the corresponding section numbers)

Entries under Access size indicates numbers of bits.

Note: Access to undefined or reserved addresses is prohibited. Since operation or continued operation is not guaranteed when these registers are accessed, do not attempt such access.

Notes: 1. Controls accessing of the SDRAM mode register. XXX depends on the setting value.

- 2. 8 bits when reading and 16 bits when writing.
- 3. If the SLEEP instruction is issued immediately after data is written to, the register value may not be reflected correctly. Before executing the SLEEP instruction, read the register.
- 4. The number of bits of each endpoint data register in USBF indicates the max value of FIFO buffer.
- 5. The endpoint stall register (EPSTL) must be accessed in 32 bits and the lower 2 bytes become valid.
- 6. 3-bit register when accessing from H-UDI interface.

# 27.2 Register Bits

Register addresses and bit names of the on-chip peripheral modules are described below.

Each line covers eight bits, and 16-bit and 32-bit registers are shown as 2 or 4 lines, respectively.

Register Abbreviation	Bit 31/ 23/15/7	Bit 30/ 22/14/6	Bit 29/ 21/13/5	Bit 28/ 20/12/4	Bit 27/ 19/11/3	Bit 26/ 18/10/2	Bit 25/ 17/9/1	Bit 24/ 16/8/0	Module

- Notes: 1. For details on initial values, please refer to the various sections related to the modules. In addition, registers whose initial values are undefined are also indicated as initialized.
- 2. Initialized by a reset signal from the RESETP pin, and retained by a reset signal from other pin.
  - 3. Some bits are initialized.
  - 4. All registers in BT module are initialized only by the power-on reset input from pin. They are not initialized by the power-on reset and manual reset generated from WDT.
  - 5. Fixed value.

# Section 28 Electrical Characteristics

# 28.1 Absolute Maximum Ratings

Table 28.1 shows the absolute maximum ratings.

**Table 28.1 Absolute Maximum Ratings** 

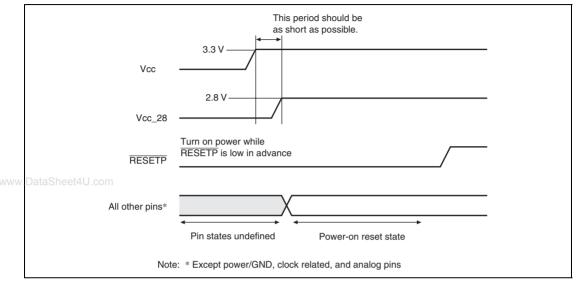

Item	Symbol	Rating	Unit
Power supply voltage (except V <sub>cc</sub> _28)	$\begin{array}{c} V_{\rm cc}(I/O) \\ V_{\rm cc}({\rm internal}) \\ V_{\rm cc}({\rm PLL}) \\ V_{\rm cc}({\rm DLL}) \\ V_{\rm cc}({\rm SREG}) \end{array}$	-0.3 to 4.2	V
Power supply voltage (V <sub>cc</sub> _28)	V <sub>cc</sub> _28	-0.3 to 4.2	V
Power supply voltage (V <sub>DD</sub> ): (using external power supply)	V <sub>DD</sub>	-0.3 to 2.1	V
Input voltage (except V <sub>cc</sub> _28)	V <sub>in</sub>	$-0.3$ to $V_{cc} + 0.3$	V
Input voltage (V <sub>cc</sub> _28)	V <sub>in</sub>	$-0.3$ to $V_{cc}_{-28} + 0.3$	V
Analog power supply voltage (DAC)	AV <sub>cc</sub> (DAC)	-0.3 to 4.2	V
Analog power supply voltage (USB)	AV <sub>cc</sub> (USB)	-0.3 to 4.2	V
Analog input voltage (USB)	V <sub>IN</sub>	-0.3 to AV <sub>cc</sub> (USB) + 0.3	V
Operating temperature	$T_{opr}$	-40 to 85	°C
Storage temperature	T <sub>stg</sub>	-55 to 125	°C

### **Usage Notes:**

- 1. Operating the chip in excess of the absolute maximum rating may result in permanent damage.
- 2. Order of turning on  $V_{cc}$ \_28 and other 3.3 V power supplies ( $V_{cc}$ ,  $AV_{cc}$ )

  Though there are no strict requirements, the following points are recommended since a cutoff of either power supply will cause unstable operation.
  - First turn on the 3.3 V power supplies except for the  $V_{cc}$ \_28 power, then turn on the  $V_{cc}$ \_28 power. This interval should be as short as possible.

- Until voltage is applied to all power supplies and a low level is input to the RESETP pin, internal circuits remain unsettled, and so pin states are also undefined. The system design must ensure that these undefined states do not cause erroneous system operation.
  Waveforms at power-on are shown in the figure below.
- The power supply voltage of  $V_{cc}$ \_28 should be within the range of the absolute maximum ratings above and also equal to the power supply voltage of the RF IC to be connected.

#### **Power-On Sequence**

# 3. Order of turning off power

Though there are no strict requirements, the following points are recommended since a cutoff of either power supply will cause unstable operation.

- In the reverse order of powering-on, first turn off the V<sub>cc</sub>\_28 power, then turn off the 3.3 V power supplies. This interval should be as short as possible.
- Pin states are undefined while only the  $V_{cc}$ \_28 power is off. The system design must ensure that these undefined states do not cause erroneous system operation.
- 4. When the built-in power supply regulator is used, each V<sub>DD</sub> pin should be connected to the capacitor to reduce noise of power supply.
- 5. When the built-in power supply regulator is used, each  $V_{DD}$  pin should not be applied voltage from outside. Also, the  $V_{DD}$  pins cannot be used to supply current to the other devices.

# 28.2 DC Characteristics

Tables 28.2 and 28.3 list the DC characteristics.

Table 28.2 DC Characteristics (1) Common Items

Condition: Ta = -40 to  $85^{\circ}$ C

Item		Symbol	Min.	Тур.	Max.	Unit	Test Conditions
Current consumption	Normal operation	I <sub>cc</sub>	_	_	350	mA	$V_{cc} = 3.3 \text{ V}$ $I\phi = 120 \text{ MHz}$ $B\phi = 60 \text{ MHz}$
Input leak current	All input pins	l <sub>in</sub>	_	_	1.0	μΑ	$V_{in} = 0.5 \text{ to } V_{cc} - 0.5 \text{ V}$
Three-state leak current	I/O, all output pins (off condition)	l <sub>STI</sub>	_	_	1.0	μА	$V_{in} = 0.5 \text{ to } V_{cc} - 0.5 \text{ V}$
Pull-up resistance	Port pin	$P_{pull}$	30	60	120	kΩ	
Pin capacity	All digital pins*	С	_	_	10	pF	
Analog power voltage (DAC)		AV <sub>cc</sub> (DAC)	2.7	3.3	3.6	V	
Analog power voltage (USB)		AV <sub>cc</sub> (USB)	3.0	3.3	3.6	V	
Internal power voltage (V <sub>DD</sub> )	supply	V <sub>DD</sub>	1.4	1.5	1.6	V	When external power supply is used.

Note: \* Power supply pins, analog pins, VBB, USB\_N, USB\_P, RDI\_CTRL4, DA0, DA1, EXTAL, XTAL, EXTAL2, XTAL2, RREF, and NC are excluded.

# Table 28.2 DC Characteristics (2-a) Except DAC and USB Related Pins

Condition: Ta = -40 to  $85^{\circ}C$ 

Item		Symbol	Min.	Тур.	Max.	Unit	Test Conditions

IRQOUT delay time	$\mathbf{t}_{IRQOD}$	_	13	ns	28.11
REFOUT delay time	t <sub>REFOD</sub>	_	13	ns	28.12
BACK delay time	t <sub>BACKD</sub>	1/2t <sub>cyc</sub>	1/2t <sub>cyc</sub> + 13	ns	28.13, 28.14
Bus tri-state delay time 1	t <sub>BOFF1</sub>	0	30	ns	
Bus tri-state delay time 2	t <sub>BOFF2</sub>	0	30	ns	_
Bus buffer-on time 1	t <sub>BON1</sub>	0	30	ns	28.13, 28.14
Bus buffer-on time 2	t <sub>BON2</sub>	0	30	ns	

Notes: 1. RESETP, NMI, IRQ4 to IRQ2, and IRQ0 are asynchronous. Changes are detected at the clock rise when the setup time shown is used. If the setup time cannot be used, detection may be delayed until the next clock rises.
The pulse width of two cycles or more in peripheral module clock (Pφ) is necessary for NMI and IRQ4 to IRQ2 and IRQ0 at the edge detection.

- 2. The upper limit of the external bus clock is 60 MHz.
- 3. tcyc means the external bus clock cycle (Bφ clock cycle)
- 4. The BOOT-E signal should not be changed excluding for the period when RESETP asserts low (during the reset period). If the BOOT-E signal is changed excluding the reset period, operation cannot be guaranteed.

## Appendix

#### A. Pin States

The initial values differ in each operating mode (reset, power-down mode, bus-released state). The following symbols are used in the table.

### Legend

O : Output
I : Input

IP : Input (Pull-up MOS on)

H : High-level outputL : Low-level output

Z1: High impedance (I/O buffer off, and pull-up MOS off)

Z2: High impedance (Output buffer off)

P: I or O, depending on register setting

K : Input pins are high-impedance, and output pins retain their state.

V: I/O buffer off, and pull-up MOS on

### Table A.1

Notes: 1. Depends on clock operating mode.

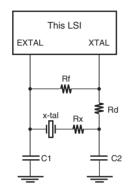

- 2. I, O, or Z, depending on register setting.

  I or O, depending on clock operating mode.
- 3. O or Z, depending on register setting in software standby mode.
- 4. O or Z, depending on register setting in bus released state.
- 5. These pins are multiplexed with the BSC function, and there are some pins which initial becomes a bus controller function. Please refer to table 24.1 for details.

### B. Usage Notes for Oscillator circuit with External Crystal Resonator

On a design of the oscillator circuit with the external crystal resonator, values of external component should be chosen from the evaluation results examined with the crystal resonator manufacturer. The evaluation result examples by Kinseki,Limited are shown below.

#### B.1 Recommended Oscillator Circuit

Crystal resonator specifications

Part number	CX-53G
Package size	5.0 × 3.2 × 1.3mm

# Evaluation results:

Evaluation room				
Crystal resonate	or part number	CX-53G	CX-53G	CX-53G
Oscillating frequ	iency (kHz)	11289.6	18432	30000
Overtone number		fundamental oscillation	fundamental oscillation	fundamental oscillation
Shunt capacitar	ice (pF)	8.0	8.0	8.0
Recommended	Rf	No connect.	No connect.	No connect.
external circuit parameters	Rd	0 Ω	0 Ω	0 Ω
	Rx	0 Ω	0 Ω	0 Ω
	C1	7pF	7pF	8pF
	C2	7pF	7pF	8pF
Characteristics	Negative resistance ( $\Omega$ )	-5442	-2826	-943
under recommended	Load capacitance (pF)	7.93	7.91	8.07
parameters	Frequency deviation ( × 10 <sup>-6</sup> )	+1.1	+1.5	-1.7
	Drive level (μW)	83	125	65

Note: The characteristics of the oscillator circuit vary with the external circuit parameters and the PCB layout. After an evaluation of the matching between the crystal resonator and the oscillator circuit sufficiently, choose the circuit parameter and PCB layout. The recommended external circuit parameters and characteristics are only guideline and recommendations. They are not guaranteed on the user application systems.

For the designing the PCB layout, refer to section B2 Note for PCB design.

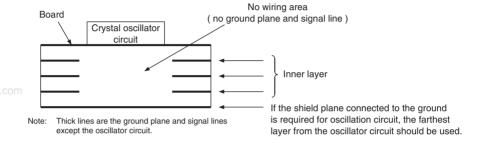

www.DataSheet4U.com

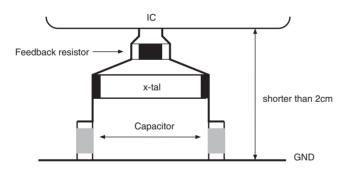

### B.2 Note on PCB design

Following items should be considered for the PCB design.

- The external oscillator circuit should be placed as near from oscillator IC as possible.
- Ground plane should not be placed under the oscillator circuit area.
- Signal line length should be shorter ( shorter than 2cm ).
- Keep spacing between two signal lines connected to the crystal resonator. Do not place them
  close to each other.
- If a shield is required for oscillator circuit, the shield area should be as small as necessary.

PCB cross section (multi-layer board)
