Cautions

Keep safety first in your circuit designs!

 Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

- 1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
- 2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- 3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein. The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors. Please also pay attention to information published by Renesas Technology Corp. by various

means, including the Renesas Technology Corp. Semiconductor home page (http://www.renesas.com).

- 4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- 5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- 6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
- 7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- 8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

General Precautions on Handling of Product

- 1. Treatment of NC Pins
- Note: Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are "used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

- 2. Treatment of Unused Input Pins
- Note: Fix all unused input pins to high or low level. Generally, the input pins of CMOS products are high-impedance input pins. If unused pins

are in their open states, intermediate levels are induced by noise in the vicinity, a passthrough current flows internally, and a malfunction may occur.

- 3. Processing before Initialization
- Note: When power is first supplied, the product's state is undefined. The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.
- 4. Prohibition of Access to Undefined or Reserved Addresses
- Note: Access to undefined or reserved addresses is prohibited. The undefined or reserved addresses may be used to expand functions, or test registers may have been be allocated to these addresses. Do not access these registers; the system's

operation is not guaranteed if they are accessed.

Configuration of This Manual

This manual comprises the following items:

- 1. General Precautions on Handling of Product
- 2. Configuration of This Manual
- 3. Preface
- 4. Contents
- 5. Overview
- 6. Description of Functional Modules
 - CPU and System-Control Modules
 - On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

- 7. List of Registers
- 8. Electrical Characteristics
- 9. Appendix

10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

www.DataSheet4U.com

Preface

The SH7729R is a microprocessor that integrates peripheral functions necessary for system configuration with a 32-bit internal architecture SH2-DSP CPU as its core.

The SH7729R's on-chip peripheral functions include a cache memory, internal X/Y memory, an interrupt controller, timers, three serial communication interfaces, a real time clock (RTC), memory management unit (MMU), a user break controller (UBC), a bus state controller (BSC), and I/O ports, making it ideal for use as a microcomputer in electronic devices that require high speed together with low power consumption.

| Intended Readership | b: This manual is intended for users undertaking the design of an application system using the SH7729R. Readers using this manual require a basic knowledge of electrical circuits, logic circuits, and microcomputers. |
|---------------------|---|
| Purpose: | The purpose of this manual is to give users an understanding of the hardware functions and electrical characteristics of the SH7729R. Details of execution instructions can be found in the SH-3, SH-3E, SH3-DSP Programming Manual, which should be read in conjunction with the present manual. |

Using this Manual:

- For an overall understanding of the SH7729R's functions Follow the Table of Contents. This manual is broadly divided into sections on the CPU, system control functions, peripheral functions, and electrical characteristics.
- For a detailed understanding of CPU functions Refer to the separate publication SH-3, SH-3E, SH3-DSP Programming Manual. Note on bit notation: Bits are shown in high-to-low order from left to right.

Related Material: The latest information is available at our Web Site. Please make sure that you have the most up-to-date information available. (http://www.renesas.com/eng/)

List of Items Revised or Added for This Version

| Sectio | n | Page | Description |
|----------------------|---|------|--|
| 5.4.2 Data Array 152 | | | Description amended The address array is mapped to H'F1000000 to H'F1FFFFF. To access an element of the data array, the 32-bit address field (for read/write access) and 32-bit data field (for write access) must be specified. The address field specifies the information that selects the entry to be accessed; the data field specifies the longword data to be written to the data array. |
| | | | In the address field, specify the entry's address in bits 11-4, L in bits 3-2 to indicate the longword's position within a line (which consists of 16 bytes), W in bits 13-12 to select the way, and H'F1 in bits 31-24 to indicate access to the data array. The L bits (3-2) specification is in the following form: 00 is longword 0, 01 is longword 1, 10 is longword 2, and 11 is longword 3. Settings for the W bits (13-12) are as follows: 00 is way 0, 01 is way 1, 10 is way 2, and 11 is way 3. Since access is not allowed crossing longword boundaries, always set 00 in bits 1-0 of the address field. |
| | | | The following two operations on the data array are possible. Note that these operations will not change the information in the address array. |
| | | | (1) Data Array Read Reads the data at the position selected by the L bits (3-2) of the address field from the entry that corresponds to the entry address and way that were specified in the address field. |
| | | | (2) Data Array Write Writes the longword data set in the data field into the entry that corresponds to the entry address and way that were specified in the address field. The longword data will be written to the entry at the position selected by the L bits (3-2) of the address field. |

| Section | Page | Description |
|---|------|---|
| 5.5.1 Invalidating a | 154 | Description amended |
| Specific Entry | | A specific cache entry can be invalidated by accessing the allocated memory cache and writing a 0 to the entry's U and V bits. The A bit is cleared to 0, and an address is specified for the entry address and the way. If the U bit of the way of the entry in question was set to 1, the entry is written back and the V and U bits specified by the write data are written to. |
| www.DataSheet4U. | | In the following example, the write data is specified in R0 and the address is specified in R1. |
| | | ; R0 = H'0000 0000 LRU = H'000, U = 0, V = 0 ; R1 = H'F000 1080, Way = 1, Entry = H'08, A = 0 ; MOV.L R0, @R1 |
| | | To invalidate all entries and ways, write 0 to the following addresses. |
| | | Addresses |
| | | F000 0000 F000 0010 |
| | | F000 0020 |
| | | : F000 3FF0 |
| | | This involves a total of 1,024 writes. |
| | | The above operation should be performed using a non-cacheable area. |
| 5.5.2 Invalidating a Specific Address | 155 | Newly added |
| 5.5.3 Reading the | | Description amended |
| Data of a Specific Entry | | ; R1=H'F100 004C; data array access, entry= <mark>H'04</mark> , Way = 0, ; longword address = 3 |
| | | , |
| | | MOV.L @R0,R1 ; Longword 3 is read. |
| 7.2.6 Interrupt | 171 | IPR (bit numbers) for SCI amended |
| Exception Handling and Priority | | (Before)IPRB(3-0) \rightarrow (After)IPRB(7-4) |
| Table 7.4 Interrupt Exception Handling Sources and Priority (IRQ Mode) | | |
| 7.3.6 Interrupt | 182 | Description amended |
| Request Register 0 (IRR0) | | When clearing an IRQ5R–IRQ0R bit to 0, read the bit while bit set to 1, and then write 0. In this case, 0 should be written only to the bits to be cleared and 1 to the other bits. The contents of the bits to which 1 is written do not change. |

| 304 | Description added |
|------|---|
| | |
| | Bit 6—CS2/CS0 Select (CS2/0) |
| | Note that the CS2/0 bit in MCSCR should always be cleared to 0 |
| 004 | (area 0 selected). |
| com | Bank Active description added |
| | In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration. |
| | The bank active mode should not be used unless the bus width |
| | for all areas is 32 bits. |
| 363 | Figure amended |
| | T ₁ T ₂ Twait T ₁ T ₂ Twait T ₁ T ₂ |
| | скю ули липи липи липи липи |
| | A25 to A0 $\frac{1}{1}$ |
| | |
| 366 | Description amended |
| | This enables 32-, 64-, 128-, or 256-Mbit memory to be connected to area 0 or area 2. However, only $CS2/0 = 0$ (area 0) should be |
| | used for MCSCR0. Table 11.15 shows MCSCR0–MCSCR7 |
| | settings and MCS[0]-MCS[7] assertion conditions. |
| 131, | Description added |
| 132 | 13. DMAC transfers should not be performed in the sleep mode |
| | under conditions other than when the clock ratio of $I\phi$ (on- chip clock) to B ϕ (bus clock) is 1:1. |
| | When the following three conditions are all met, the |
| | frequency control register (FRQCR) should not be changed |
| | while a DMAC transfer is in progress. |
| | Bits IFC2 to IFC0 are changed. |
| | STC2 to STC0 in FRQCR are not changed. |
| | The clock ratio of l |
| | 15. If the following three conditions are all met, big-endian access is used when the DMAC is used to transfer data from |
| | XY memory, even in the little-endian mode. |
| | The source address for the transfer is in XY memory. |
| | The indirect address mode is used. |
| | The byte size data is transferred. |
| | The data format is little-endian. |

| Section | Page | Description |
|--|------|--|
| 17.4 SCIF Interrupts | 594 | Description amended |
| Table 17.10 SCIF Interrupt Sources www.DataSheet4U.com | | When the TDFE flag in the serial status register (SCSSR) is set to 1, a TXI interrupt request is generated. The DMAC can be activated and data transfer performed when this interrupt is generated. When data exceeding the transmit trigger number is written to the transmit data register (SCETDR) by the DMAC 1 is |
| | | written to the transmit data register (SCFTDR) by the DMAC, 1 is read from the TDFE flag, after which 0 is written to it to clear it. |
| | | When the RDF flag in SCSSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed when the RDF flag in SCSSR is set to 1. When receive data less than the receive trigger number is read from the receive data register (SCFRDR) by the DMAC, 1 is read from the RDF flag, after which 0 is written to it to clear it. |
| | | Table amended |
| | | (Before)Priority on Reset Release \rightarrow (After)Priority |
| 17.5 Usage Notes | 595 | Description amended |
| | | 1. SCFTDR Writing and TDFE Flag: However, if the number of data bytes written to SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again even after having been cleared to 0. TDFE clearing should therefore be carried out after data exceeding the specified transmit trigger number has been written to SCFTDR. |

Section 1 Overview

1.1 Features

The SH7729R is a single-chip RISC microprocessor that integrates a 32-bit RISC-type SuperH RISC engine architecture CPU with a digital signal processing (DSP) extension as its core, together with cache memory, an on-chip X/Y memory, and a memory management unit (MMU), as well as peripheral functions required for system configuration such as a timer, a realtime clock, an interrupt controller, and a serial communication interface. The SH7729R includes data protection, virtual memory, and other functions provided by incorporating an MMU, into a SuperH Series microprocessor (SH-1 or SH-2). The provision of on-chip DSP functions enables applications that previously required the use of two chips—a microprocessor and a DSP—to be implemented with a single chip.

The SH7729R chip has the same peripheral modules as the SH7729. High-speed data transfers can be formed by an on-chip direct memory access controller (DMAC), and an external memory access support function enables direct connection to different kinds of memory. The SH7729R microprocessor also supports an infrared communication function, an A/D converter, and a D/A converter.

A powerful built-in power management function keeps power consumption low, even during highspeed operation. The SH7729R can run at six times the system bus operating speed, making it also ideal for devices such as PDAs that require both high speed and low power consumption.

The features of the SH7729R are listed in table 1.1.

Table 1.1SH7729R Features

| ltem | Features |
|------|--|
| CPU | Original Renesas Technology SuperH architecture |
| | Compatible with SH-1, SH-2, and SH-3 series at object code level |
| | 32-bit internal data bus www.DataSheet4U.com |
| | General-registers |
| | — Sixteen 32-bit general registers (eight 32-bit shadow registers) |
| | Eight 32-bit control registers |
| | — Four 32-bit system registers |
| | RISC-type instruction set |
| | Instruction length: 16-bit fixed length for improved code efficiency |
| | Load/store architecture |
| | Delayed branch instructions |
| | Instruction set based on C language |
| | Instruction execution time: one instruction/cycle for basic instructions |
| | Logical address space: 4 Gbytes |
| | Space identifier ASID: 8 bits, 256 logical address spaces |
| | Five-stage pipeline |
| DSP | Mixture of 16-bit and 32-bit instructions |
| | Multiplier, ALU, barrel shifter, and DSP register |
| | • 16-bit \times 16-bit \rightarrow 32-bit one cycle multiplier |
| | Large DSP data registers |
| | — Six 32-bit data registers |
| | — Two 40-bit data registers |
| | Extended Harvard Architecture for DSP data bus |
| | — Two data buses |
| | — One instruction bus |
| | Max. four parallel operations: ALU, multiply, and two load or store |
| | Two addressing units to generate addresses for two memory access |
| | DSP data addressing modes: increment, indexing (with or without modulo addressing) |
| | Zero-overhead repeat loop control |
| | Conditional execution instructions |
| | User DSP mode and privileged DSP mode |

| ltem | Features |
|--------------------------------|---|
| Clock pulse generator (CPG) | Clock mode: Input clock can be selected from external input (EXTAL or CKIO) or crystal oscillator |
| | Three types of clocks generated: |
| | — CPU clock: 1–24 times the input clock, maximum 200 MHz |
| | eet49-eoBus clock: 1–4 times the input clock, maximum 66.67 MHz |
| | Peripheral clock: 1/4–4 times the input clock, maximum 33.34 MHz |
| | Power-down modes: |
| | — Sleep mode |
| | — Standby mode |
| | — Module standby mode |
| | One-channel watchdog timer |
| Memory | • 4 Gbytes of address space, 256 address spaces (8-bit ASID) |
| management | Page unit sharing |
| unit (MMU) | Supports multiple page sizes: 1 kbyte or 4 kbytes |
| | 128-entry, 4-way set associative TLB |
| | Supports software selection of replacement method and random-replacement algorithms |
| Cache memory | 16-kbyte cache, mixed instruction/data |
| | 256 entries, 4-way set associative, 16-byte block length |
| | Write-back, write-through, LRU replacement algorithm |
| | 1-stage write-back buffer |
| | Maximum 2 ways of the cache can be locked |
| X/Y memory | User-selectable mapping mechanism |
| | Fixed mapping for realtime applications (privileged DSP mode) |
| | Automatic mapping through TLB (user DSP mode) |
| | Three independent read/write ports |
| | — 8-/16-/32-bit access from the CPU |
| | Maximum two 16-bit accesses from the DSP |
| | — 8-/16-/32-bit and 16-byte access from the DMAC |
| | 8-kbyte RAM each for X and Y memory |
| Interrupt | • 7 external interrupt pins (NMI, IRQ5–IRQ0) |
| controller (INTC) | Level interrupt pins: 15 levels |
| | 16 port interrupt pins (PINT15–PINT0) |
| | On-chip peripheral interrupts: Priority level set for each module |

| Item | Features |
|---------------------------------------|--|
| User break | Two break channels |
| controller (UBC) | • Addresses, data values, type of access, and data size can all be set as break conditions |
| | Supports a sequential break function |
| Bus statevw.DataS controller (BSC) | Physical address space divided into six areas (area 0, areas 2 to 6), each a maximum of 64 Mbytes, with the following features settable for each area: Bus size (8, 16, or 32 bits) |
| | Number of wait cycles (also supports a hardware wait function) |
| | — Specifying the memory to be connected to each area enables direct connection to SRAM, DRAM, synchronous DRAM, and burst ROM |
| | — Supports PCMCIA interface (2 channels) |
| | Outputs chip select signal (CS0, CS2–CS6) for corresponding area |
| | Synchronous DRAM refresh function |
| | Programmable refresh interval |
| | — Supports self-refresh mode |
| | Synchronous DRAM burst access function |
| | Big or little endian can be set |
| User debugging | E10A emulator support |
| Interface (UDI) | JTAG-compliant |
| | Realtime branch trace |
| | 1-kbyte on-chip RAM for fast emulation program execution |
| Timer (TMU) | 3-channel auto-reload-type 32-bit timer |
| | Input capture function |
| | Selection of six counter input clocks |
| | Maximum resolution: 2 MHz |
| Realtime clock | Built-in clock, calendar functions, and alarm functions |
| (RTC) | On-chip 32-kHz crystal oscillator circuit with a maximum resolution (cycle interrupt) of 1/256 second |
| Serial communi- | Asynchronous mode or clock synchronous mode can be selected |
| cation interface 0 (SCI0) | Full-duplex communication |
| (6610) | Supports smart card interface |
| Serial communi- | 16-byte FIFO for transmission/reception |
| cation interface 1 (SCI1) | DMA transfer capability |
| | IrDA: interface based on 1.0 |

| ltem | Features | i | | | | | |

Notes: 1. Must be connected to the power supply even when the RTC is not used.

2. Except in hardware standby mode, all power supply pins must be connected to the system power supply. (Supply power constantly.) In hardware standby mode, power must be supplied at least to V_{CC} -RTC and V_{SS} -RTC. If power is not supplied to power supply pins other than V_{CC} -RTC and V_{SS} -RTC, hold the CA pin low.

3. 2.0 V in 200 MHz models, 1.9 V in 167 MHz models, 1.8 V in 133 MHz models, 1.7 V in 100 MHz models.

 Drive high when using the user system alone, and not using an emulator or the UDI. When this pin is low or open, <u>RESETP</u> may be masked (see section 23 User Debugging Interface (UDI)).

5. B2, B1, C1, U1, V1, W1, V2, W2, W3, W17, W18, W19, V18, V19, B19, A19, B18, A18, A17, A3, A2, and A1 are NC pins. No connection should be made to these pins.

6. If EXTAL2 is not used, pull this pin up to the Vcc-RTC level.

Section 2 CPU

2.1 Registers

The SH7729R has the same registers as the SH-3. In addition, the SH7729R also supports the same DSP-related registers as in the SH2-DSP. The basic software-accessible registers are divided into four distinct groups:

- General registers
- Control registers
- System registers
- DSP registers

With the exception of a number of DSP registers, all of these registers are 32-bit width. The general registers are accessible from user mode, with R0–R7 banked to provide each processor mode access to a separate set of R0–R7 registers (i.e. R0–R7_BANK0, and R0–R7_BANK1). In privileged mode, the register bank bit (RB) in the status register (SR) defines which set of banked registers (R0–R7_BANK0 or R0–R7_BANK1) are accessed as general registers, and which are accessed only by LDC/STC instructions.

The control registers can be accessed by LDC/STC instructions. The GBR, RS, RE, and MOD registers can also be accessed in user mode. Control registers are:

- SR: Status register
- SSR: Saved status register
- SPC: Saved program counter
- GBR: Global base register
- VBR: Vector base register
- RS: Repeat start register (DSP mode only)
- RE: Repeat end register (DSP mode only)
- MOD: Modulo register (DSP mode only)

The system registers are accessed by the LDS/STS instructions (the PC is software-accessible, but is included here because its contents are saved in, and restored from, SPC in exception handling). The system registers are:

- MACH: Multiply and accumulate high register
- MACL: Multiply and accumulate low register
- PR: Procedure register
- PC: Program counter

www.DataSheet4U.com Rev. 5.0, 09/03, page 19 of 806

This section explains the usage of these registers in different modes.

Figures 2.1 and 2.2 show the register configuration in each processing mode.

Switching between user mode and privileged mode is carried out by means of the operation mode bit (MD) in the status register.

The DSP mode is switched by means of the DSP bit in the status register (see figure 2.5).

2.1.1 General Registers

There are sixteen 32-bit general registers (Rn), designated R0 to R15. The general registers are used for data processing and address calculation.

With SuperH microcomputer type instructions, R0 is used as an index register. With a number of instructions, R0 is the only register that can be used. R15 is used as the stack pointer (SP). In exception handling, R15 is used to reference the stack when saving and restoring the status register (SR) and program counter (PC).

With DSP type instructions, eight of the sixteen general registers are used for addressing of X and Y data memory and data memory (single data) that uses the L-bus.

To access X memory, R4 and R5 are used as the X address register [Ax] and R8 is used as the X index register [Ix]. To access Y memory, R6 and R7 are used as the Y address register [Ay] and R9 is used as the Y index register [Iy]. To access single data that uses the L-bus, R2, R3, R4, and R5 are used as the single data address register [As] and R8 is used as the single data index register [Is].

Figure 2.3 shows the general registers, which are identical to those of the SH3, when DSP extension is disabled.

| R0 ^{*1 *2} | General Registers (when not in DSP mode) |
|---------------------|---|
| R1*2 | |
| R2 ^{*2} | Notes: 1. R0 functions as an index register in the indexed register-indirect addressing mode |
| R3 ^{*2} | and indexed GBR-indirect addressing mode. |
| R4 ^{*2} | In some instructions, only R0 can be used as |
| R5 ^{*2} | the source register or destination register. |
| R6 ^{*2} | 2. R0–R7 are banked registers. In user mode, |
| R7 ^{*2} | BANK0 is used. In privileged mode, SR.RB |
| R8 | specifies BANK. |
| R9 | SR.RB = 0; BANK0 is used SR.RB = 1; BANK1 is used |

| R14 | |
| R15 | |

Figure 2.3 General Purpose Registers (Not in DSP Mode)

On the other hand, registers R2–R9 are also used for DSP data address calculation when DSP extension is enabled (see figure 2.4). Other symbols that represent the purpose of the registers in DSP type instructions is shown in [].

| www.DataShe R0 U.com | General Registers (DSP mode enabled) | | |
|-----------------------------|---|--|--|
| R1 | | | |
| R2 [As] | X or Y data transfer operation | | |
| R3 [As] | R4, 5 [Ax]: Address register set for X data memory. | | |

| R13 | 1 | | |
| R14 | 1 | | |
| R15 | - | | |

Figure 2.4 General Purpose Registers (DSP Mode)

DSP type instructions can access X and Y data memory simultaneously. To specify addresses for X and Y data memory, two address pointer sets are provided. These are:

R8[Ix], R4,5[Ax] for X memory access, and R9[Iy], R6,7[Ay] for Y memory access.

The symbols R2–R9 are used by the assembler, but users can use the register name (alias) to indicate the purpose of the register in the DSP instruction. The coding in assembler is as follows.

Ix: .REG (R8)

www.DataSheet4U.com

The name Ix is the alias for R8. Other aliases are as follows.

| Ax0: | .REG | (R4) | | |
|------|------|------|---|--|
| Ax1: | .REG | (R5) | | |
| Ix: | .REG | (R8) | | |
| Ay0: | .REG | (R6) | | |
| Ay1: | .REG | (R7) | | |
| Iy: | .REG | (R9) | | |
| As0: | .REG | (R4) | ; | This is optional, if another alias is required for single data transfer. |
| As1: | .REG | (R5) | ; | This is optional, if another alias is required for single data transfer. |
| As2: | .REG | (R2) | | |
| As3: | .REG | (R3) | | |
| Is: | .REG | (R8) | ; | This is optional, if another alias is required for single data transfer. |
| | | | | |

2.1.2 Control Registers

The SH7729R has 8 control registers: SR, SSR, SPC, GBR, VBR, RS, RE, and MOD (figure 2.5). SSR, SPC, GBR and VBR are the same as the SH-3 registers.

In SR, there are six additional control bits: RC[11:0], RF0, RF1, DMX, DMY and DSP. Bits DMX, DMY, RC[11:0], and RF[1:0] can be modified in privileged mode, privileged DSP mode, and use DSP mode. DMX and DMY are used for modulo addressing control. If DMX is 1, the modulo addressing mode is effective for the X memory address pointer, Ax (R4 or R5). If DMY is 1, the modulo addressing mode is effective for the Y memory address pointer, Ay (R6 or R7). However, both X and Y address pointers cannot be operated in modulo addressing mode even though both DMX and DMY bits are set. The case where DMX = DMY = 1 is reserved for future expansion. Modulo addressing is available for X and Y data transfer operations (MOVX and MOVY), but not for a single data transfer operation (MOVS).

RF1 and RF0 hold information on the number of repeat steps, and are set when a SETRC instruction is executed. When RF[1:0] = 00, the current repeat module consists of one instruction step. RF[1:0] = 01 means two instruction steps, RF[1:0] = 11 means three instruction steps, and RF[1:0] = 10 means the current repeat module consists of four or more instructions.

Although RC[11:0] and RF[1:0] can be changed by a store/load to SR, use of the dedicated manipulation instruction SETRC is recommended.

www.DataSheet4U.com Rev. 5.0, 09/03, page 25 of 806

SR also has a 12-bit repeat counter, RC, which is used for efficient loop control. The repeat start register (RS) and repeat end register (RE) are also provided for loop control. They hold the start and end addresses of a loop (the contents of the RS and RE registers are slightly different from the actual loop start and end addresses). The modulo register, MOD, is provided to implement modulo addressing for circular data buffering. MOD holds the modulo start address (MS) and modulo end address (ME).

www.DataSheet4U.com

In order to access RS, RE, and MOD, load/store (control register) instructions for these registers are provided. An example for RS is as follows:

LDC Rm,RS; Rm \rightarrow RS LDC.L @Rm+,RS; (Rm) \rightarrow RS, Rm+4 \rightarrow Rm STC RS,Rn; RS \rightarrow Rn STC.L RS,@-Rn; Rn-4 \rightarrow Rn, RS \rightarrow (Rn)

Address set instructions for RS and RE are also provided.

LDRS @(disp,PC); disp $\times 2 + PC \rightarrow RS$ LDRE @(disp,PC); disp $\times 2 + PC \rightarrow RE$

| ME(Modulo end address) | MS(Modulo start address) | Modulo register |

Saved status register (SSR)

Stores current SR value at time of exception and returns value to SR when returning to instruction stream from exception or interrupt handler.

Saved program counter (SPC)

Stores current PC value at time of exception to indicate return address on completion of exception handling.

Global base register (GBR)

Stores base address of GBR-indirect addressing mode. The GBR-indirect addressing mode is used for data transfer and logical operations on the on-chip peripheral module register area.

Vector base register (VBR) Stores base address of exception vector area.

Repeat start register (RS) Used in DSP mode only. Indicates start address of repeat loop.

Repeat end register (RE) Used in DSP mode only. Indicates end address of repeat loop. Modulo register(MOD) Used in DSP mode only. MD[31:16] [ME]: Modulo end address, MD[15:0][MS]: Modulo start address. In X/Y operand address generation, the CPU compares the address with ME, and if it is the same, loads MS in either the X or Y operand address register (depending on bits DMX and DMY in the SR register).

Figure 2.5 Control Registers (cont)

www.DataSheet4U.com

Details of the status register (SR) when STC/LDC instructions are used are shown below.

- 1. When the DSP is not operating, operation is the same as for the SH-3.
- 2. In privileged DSP mode, operation is the same as in privileged mode.
- 3. In user DSP mode, SR can be read with an STC instruction.
- 4. In user DSP mode, an LDC instruction can be issued for SR, but in this case DSP-related bits are not write-protected.

Table 2.2 Operation of SR Bits in Each SH-3 DSP Mode

Legend

S (STC): Store SR to Rn, SR->Rn

L (LDC): Load Rn to Sr,Rn->SR

OK: STC/LDC operation is enabled.

Invalid instruction: Exception occurs when an invalid instruction is executed.

NG: Previous value is retained. No change.

www.DataSheet4U.com Rev. 5.0, 09/03, page 29 of 806

2.1.3 System Registers

The SH7729R has four system registers, MACL, MACH, PR, and PC (figure 2.6).

Figure 2.6 System Registers

The DSR, A0, X0, X1, Y0, and Y1 registers are also treated as system registers. Therefore, instructions for data transfer between general registers and system registers are supported for these registers.

2.1.4 DSP Registers

The SH7729R has eight data registers and one status register as DSP registers (figure 2.7). The data registers are 32-bit width with the exception of registers A0 and A1. Registers A0 and A1 include 8 guard bits (fields A0G and A1G), giving them a total width of 40 bits.

Three kinds of operation access the DSP data registers. The first is DSP data processing. When a DSP fixed-point data operation uses A0 or A1 as the source register, it uses the guard bits (bits 39–32). When it uses A0 or A1 as the destination register, guard bits 39–32 are valid. When a DSP fixed-point data operation uses a DSP register other than A0 or A1 as the source register, it signextends the source value to bits 39–32. When it uses one of these registers as the destination register, bits 39–32 of the result are discarded.

The second kind of operation is an X or Y data transfer operation, "MOVX.W MOVY.W". This operation accesses the X and Y memories through the 16-bit X and Y data buses (figure 2.8). The register to be loaded or stored by this operation always comprises the upper 16 bits (bits 31–16). X0 or X1 can be the destination of an X memory load and Y0 or Y1 can be the destination of a Y memory load, but no other register can be the destination register in this operation. When data is read into the upper 16 bits of a register (bits 31–16), the lower 16 bits of the register (bits 15–0) are automatically cleared.

A0 and A1 can be stored in the X or Y memory using the X or Y data transfer instructions MOVX.W and MOVY.W, but no other registers can be stored.

Rev. 5.0, 09/03, page 30 of 806

www.DataSheet4U.com

The third kind of operation is a single-data transfer instruction, "MOVS.W" or "MOVS.L". These instructions access any memory location through the LDB (figure 2.8). All DSP registers connect to the LDB and can be the source or destination register of the data transfer. These instructions have word and longword access modes. In word mode, registers to be loaded or stored by this instruction comprise the upper 16 bits (bits 31–16) for DSP registers except A0G and A1G. When data is loaded into a register other than A0G and A1G in word mode, the lower half of the register is cleared. When A0 or A1 is used, the data is sign-extended to bits 39–32 and the lower half is cleared. When A0G or A1G is the destination register in word mode, data is loaded into an 8-bit register, but A0 or A1 is not cleared. In longword mode, when the destination register is A0 or A1, it is sign-extended to bits 39–32.

Tables 2.3 and 2.4 show the data type of registers used in DSP instructions. Some instructions cannot use some registers shown in the tables because of instruction code limitations. For example, PMULS can use A1 as the source register, but cannot use A0. These tables ignore details of register selectability.

| Pogiatoro | Instructions | | Guard Bits | Regis | ter Bits |

| Bits | Name (Abbreviation) | Function |
|------|------------------------------|---|
| 31–8 | Reserved bits | 0: Always read as 0; always use 0 as the write value |
| 7 | Signed Greater Than bit (GT) | Indicates that the operation result is positive (except 0), or that operand 1 is greater than operand 2 |
| WWV | /.DataSheet4U.com | 1: Operation result is positive, or operand 1 is greater than operand 2 |
| 6 | Zero bit (Z) | Indicates that the operation result is zero (0), or that operand 1 is equal to operand 2 |
| | | 1: Operation result is zero (0), or operand 1 is equal to operand 2 |
| 5 | Negative bit (N) | Indicates that the operation result is negative, or that operand 1 is smaller than operand 2 |
| | | 1: Operation result is negative, or operand 1 is smaller than operand 2 |
| 4 | Overflow bit (V) | Indicates that the operation result has overflowed |
| | | 1: Operation result has overflowed |
| 3–1 | Condition Select bits (CS) | Designate the mode for selecting the operation result status to be set in the DC bit |
| | | Do not set these bits to 110 or 111 |
| | | 000: Carry/borrow mode |
| | | 001: Negative value mode |
| | | 010: Zero mode |
| | | 011: Overflow mode |
| | | 100: Signed greater mode |
| | | 101: Signed greater than or equal to mode |
| 0 | DSP Condition bit (DC) | Sets the status of the operation result in the mode designated by the CS bits |
| | | 0: Designated mode status has not occurred (false) |
| | | 1: Designated mode status has occurred |

Table 2.5DSR Register Bits

Figure 2.8 Connections of DSP Registers and Buses

The DSP unit has one DSP status register (DSR). DSR holds the status of DSP data operation results (zero, negative, and so on) and has a DC bit which is similar to the T bit in the CPU. The DC bit indicates one of the status flags. A DSP data processing instruction controls its execution based on the DC bit. This control affects only the operations in the DSP unit; it controls the update of DSP registers only. It cannot control operations in the CPU, such as address register updating and load/store operations. Control bits CS[2:0] specify the condition to be reflected in the DC bit.

Unconditional DSP type data operations, except PMULS, MOVX, MOVY and MOVS, update the condition flags and DC bit, but no CPU instructions, including MAC instructions, update the DC bit. Conditional DSP type instructions do not update DSR either.

DSR is assigned as a system register and the following load/store instructions are provided:

STS DSR,Rn; STS.L DSR,@-Rn; LDS Rn,DSR; LDS.L @Rn+,DSR;

When DSR is read by an STS instruction, the upper bits (bits 31 to 8) are all 0.

www.DataSheet4U.com

2.2 Data Formats

2.2.1 Register Data Format (Non-DSP Type)

Register operands are always longwords (32 bits) (figure 2.9). When the memory operand is only a byte (8 bits) or a word (16 bits), it is sign-extended into a longword when loaded into a register.

Figure 2.9 Longword Operand

2.2.2 DSP-Type Data Formats

The SH7729R has several different data formats that depend on the instruction. This section explains the data formats for DSP type instructions.

Figure 2.10 shows three DSP-type data formats with different binary point positions. A CPU-type data format with the binary point to the right of bit 0 is also shown for reference.

The DSP-type fixed point data format has the binary point between bit 31 and bit 30. The DSP-type integer format has the binary point between bit 16 and bit 15. The DSP-type logical format does not have a binary point. The valid data lengths of the data formats depend on the instruction and the DSP register.

www.DataSheet4U.com Rev. 5.0, 09/03, page 35 of 806

The shift amount for the arithmetic shift (PSHA) instruction has a 7-bit field that can represent values from -64 to +63, but -32 to +32 are valid numbers for the instruction. Also the shift amount for a logical shift operation has a 6-bit field, but -16 to +16 are valid numbers for the instruction.

2.2.3 Memory Data Formats

Memory data formats are classified into byte, word, and longword. Byte data can be accessed from any address, but an address error will occur if word data starting from an address other than 2n or longword data starting from an address other than 4n is accessed. In such cases, the data accessed cannot be guaranteed (figure 2.11).

Figure 2.11 Byte, Word, and Longword Alignment

Either big-endian or little-endian byte order can be selected for the data format, according to the MD5 pin at reset. When MD5 is low at reset, this LSI operates in big-endian mode. When MD5 is high at reset, this LSI operates in little-endian mode.

2.3 Features of CPU Core Instructions

The CPU core instructions are RISC-type instructions with the following features:

Fixed 16-Bit Length: All instructions have a fixed length of 16 bits. This improves program code efficiency.

One Instruction per State: Pipelining is used, and basic instructions can be executed in one state.

Data Size: The basic data size for operations is longword. Byte, word, or longword can be selected as the memory access size. Memory byte or word data is sign-extended and operated on as longword data. Immediate data is sign-extended to longword size for arithmetic operations or zero-extended to longword size for logical operations.

www.DataSheet4U.com Rev. 5.0, 09/03, page 37 of 806

| SH7729R | CPU | Description | Example | of Other CPU |
|--------------|-----------------------------|---|---------|--------------|
| MOV.W ADD | @(disp,PC),R1 R1,R0 | R1 sign-extended to 32 bits, becomes H'00001234, and is then operated on by the ADD | ADD.W | #H'1234,R0 |
| .DATA.W | w.DataSheet4U.com H'1234 | instruction. | | |

Table 2.6Word Data Sign Extension

Note: Immediate data is referenced by @(disp,PC).

Load/Store Architecture: Basic operations are executed between registers. In operations involving memory, data is first loaded into a register (load/store architecture). However, bit manipulation instructions such as AND are executed directly on memory.

Delayed Branching: Unconditional branch instructions, etc., are executed as delayed branches. With a delayed branch instruction, the branch is made after execution of the instruction (called the slot instruction) immediately following the delayed branch instruction. This minimizes disruption of the pipeline when a branch is made.

With a delayed branch, the actual branch operation occurs after execution of the slot instruction. However, instruction execution for register updating, etc., excluding the branch operation, is performed in delayed branch instruction \rightarrow delay slot instruction order. For example, even though the contents of the register holding the branch destination address are changed in the delay slot, the branch destination address remains as the register contents prior to the change.

| Table 2.7 | Delayed | Branch | Instructions |
|-----------|---------|--------|--------------|
|-----------|---------|--------|--------------|

| SH77 | 29R CPU | Description | Exampl | e of Other CPU |
|------|---------|----------------------------------|--------|----------------|
| BRA | TRGET | ADD is executed before branch to | ADD.W | R1,R0 |
| ADD | R1,R0 | TRGET. | BRA | TRGET |

Multiply/Multiply-and-Accumulate Operations: A $16 \times 16 \rightarrow 32$ multiply operation is executed in 1 to 3 states, and a $16 \times 16 + 64 \rightarrow 64$ multiply-and-accumulate operation in 2 to 3 states. A $32 \times 32 \rightarrow 64$ multiply operation and a $32 \times 32 + 64 \rightarrow 64$ multiply-and-accumulate operation are each executed in 2 to 5 states.

T Bit: The result of a comparison is indicated by the T bit in the status register (SR), and a conditional branch is performed according to whether the result is True or False.

| SH7729R | CPU | Description Example of Othe | | e of Other CPU |
|---------|-------------------------|--|-------|----------------|
| CMP/GE | v. B1:R0 eet4U.c | If $R0 \ge R1$, the T bit is set. | CMP.W | R1,R0 |
| BT | TRGET0 | A branch is made to TRGET0 | BGE | TRGET0 |
| BF | TRGET1 | if $R0 \ge R1$, or to TRGET1 if $R0 < R1$. | BLT | TRGET1 |
| ADD | #–1,R0 | The T bit is not set by ADD. | SUB.W | #1,R0 |
| CMP/EQ | #0,R0 | If $R0 = 0$, the T bit is set. | BEQ | TRGET |
| BT | TRGET | A branch is made if $R0 = 0$. | | |

Table 2.8 T Bit

Immediate Data: Byte immediate data is placed inside the instruction code. Word and longword immediate data is not placed inside the instruction code, but in a table in memory. The table in memory is referenced with an immediate data transfer instruction (MOV) using PC-relative addressing mode with displacement.

SH7729R CPU **Example of Other CPU** Type 8-bit immediate MOV #H'12,R0 MOV.B #H'12,R0 16-bit immediate @(disp,PC),R0 #H'1234,R0 MOV.W MOV.WDATA.W H'1234 32-bit immediate MOV.L @(disp,PC),R0 MOV.L #H'12345678,R0DATA.L H'12345678

Table 2.9 Immediate Data Referencing

Note: Immediate data is referenced by @(disp,PC).

Absolute Addresses: When data is referenced by absolute address, the absolute address value is placed in a table in memory beforehand. Using the method whereby immediate data is loaded when an instruction is executed, this value is transferred to a register and the data is referenced using register indirect addressing mode.

Table 2.10 Absolute Address Referencing

| www.DataShe | et4U.com SH7729 | R CPU | Example of Other CPU |
|------------------|--------------------|---------------|----------------------|
| Absolute address | MOV.L | @(disp,PC),R1 | MOV.B @H'12345678,R0 |
| | MOV.B | @R1,R0 | |
| | | | |
| | .DATA.L | H'12345678 | |
| | | | |

16-Bit/32-Bit Displacement: When data is referenced with a 16- or 32-bit displacement, the displacement value is placed in a table in memory beforehand. Using the method whereby immediate data is loaded when an instruction is executed, this value is transferred to a register and the data is referenced using indexed register indirect addressing mode.

Table 2.11 Displacement Referencing

| Туре | SH7729R CPU | Example of Other CPU |
|---------------------|---------------------|-----------------------|
| 16-bit displacement | MOV.W @(disp,PC),R0 | MOV.W @(H'1234,R1),R2 |
| | MOV.W @(R0,R1),R2 | |
| | | |
| | .DATA.W H'1234 | |

2.4 Instruction Formats

2.4.1 CPU Instruction Addressing Modes

The following table shows addressing modes and effective address calculation methods for instructions executed by the CPU core.

| Addressing Mode | Instruction Format | Effective Address Calculation Method | Calculation Formula |
|---|-----------------------|---|--|
| Register direct | Rn | Effective address is register Rn. (Operand is register Rn contents.) | _ |
| Register indirect Register indirect with | @Rn @Rn+ | Effective address is register Rn contents. Rn Rn Effective address is register Rn contents. A constant is added to Rn after instruction | Rn Rn |
| post-increment | | execution: 1 for a byte operand, 2 for a word operand, 4 for a longword operand. $\begin{array}{c} Rn \\ \hline Rn + 1/2/4 \\ \hline 1/2/4 \end{array}$ | After instruction execution Byte: $Rn + 1 \rightarrow Rn$ Word: $Rn + 2 \rightarrow Rn$ Longword: $Rn + 4$ $\rightarrow Rn$ |
| Register indirect with pre-decrement | @-Rn | Effective address is register Rn contents, decremented by a constant beforehand: 1 for a byte operand, 2 for a word operand, 4 for a longword operand. Rn Rn Rn 1/2/4 1/2/4 | Byte: $Rn - 1 \rightarrow Rn$ Word: $Rn - 2 \rightarrow Rn$ Longword: $Rn - 4$ $\rightarrow Rn$ (Instruction executed with Rn after calculation) |

Table 2.12 Addressing Modes and Effective Addresses for CPU Instructions

2.4.2 DSP Data Addressing

Two different memory accesses are made with DSP instructions. The two kinds of instructions are X and Y data transfer instructions (MOVX.W, MOVY.W) and single data transfer instructions (MOVS.W, MOVSL). The data addressing is different for these two kinds of instruction. An overview of the data transfer instructions is given in table 2.13.

ww.DataSheet4U.com

| | X/Y Data Transfer Processing (MOVX.W, MOVY.W) | Single Data Transfer Processing (MOVS.W, MOVS.L) |
|----------------------|--|---|
| Address register | Ax: R4, R5, Ay: R6, R7 | As: R2, R3, R4, R5 |
| Index register | lx: R8, ly: R9 | ls: R8 |
| Addressing | Nop/Inc (+2)/index addition: post-increment | Nop/Inc (+2, +4)/index addition: post-increment |
| | — | Dec (-2, -4): pre-decrement |
| Modulo addressing | Possible | Not possible |
| Data bus | XDB, YDB | LDB |
| Data length | 16 bits (word) | 16/32 bits (word/longword) |
| Bus contention | No | Yes |
| Memory | X/Y data memory | Entire memory space |
| Source register | Dx, Dy: A0, A1 | Ds: A0/A1, M0/M1, X0/X1, Y0/Y1, A0G, A1G |
| Destination register | Dx: X0/X1, Dy: Y0/Y1 | Ds: A0/A1, M0/M1, X0/X1, Y0/Y1, A0G, A1G |

Table 2.13 Overview of Data Transfer Instructions

X/Y Data Addressing: With DSP instructions, the X and Y data memory can be accessed simultaneously using the MOVX.W and MOVY.W instructions. Two address pointers are provided for DSP instructions to enable simultaneous access to X and Y data memory. Only pointer addressing can be used with DSP instructions; immediate addressing is not available. Address registers are divided into two, with register R4 or R5 functioning as the X memory address register (Ax), and register R6 or R7 as the Y memory address register (Ay). The following three kinds of addressing can be used with X and Y data transfer instructions.

1. Non-update address register addressing:

The Ax and Ay registers are address pointers. They are not updated.

2. Addition index register addressing:

The Ax and Ay registers are address pointers. After a data transfer, the value of the Ix or Iy register is added to each (post-increment).

www.DataSheet4U.com Rev. 5.0, 09/03, page 45 of 806

3. Increment address register addressing:

The Ax and Ay registers are address pointers. After a data transfer, they are each incremented by 2 (post-increment).

There is an index register for each address pointer. The R8 register is the index register (Ix) for the X memory address register (Ax), and the R9 register is the index register (Iy) for the Y memory address register (Ay).^{14U.com}

The X and Y data transfer instructions perform word-length processing, and use 16-bit access to the X/Y data memory. A value of 2 is therefore added to the address register in the increment processing. To perform decrementing, -2 is set in the index register and addition index register addressing is specified. In X/Y data addressing, only bits 1 to 15 of the address pointer are valid. When using X/Y data addressing, 0 must always be written to bit 0 of the address pointer and index register.

X/Y data transfer addressing is shown in figure 2.12. When accessing X and Y memory using the X and Y buses, the upper word of Ax (R4 or R5) and Ay (R6 or R7) is ignored. The result of @AY+ or @Ay+Iy is stored in the lower word of Ay, while the upper word retains its original value.

Figure 2.12 X and Y Data Transfer Addressing

Single Data Addressing: DSP instructions include two single data transfer instructions (MOVS.W, MOVS.L) that load data into, or store data from, a DSP register. With these instructions, one of registers R2 to R5 is used as the single data transfer address register (As).

The following four kinds of addressing can be used with single data transfer instructions.

www.DataSheet4U.com

1. Non-update address register addressing:

The As register is an address pointer. It is not updated.

2. Addition index register addressing:

The As register is an address pointer. After a data transfer, the value of the Is register is added to the As register (post-increment).

3. Increment address register addressing:

The As register is an address pointer. After a data transfer, the As register is incremented by 2 or 4 (post-increment).

4. Decrement address register addressing:

The As register is an address pointer. Before a data transfer, -2 or -4 is added to the As register (i.e. 2 or 4 is subtracted) (pre-decrement).

The R8 register is the index register (Is) for the address pointer (As). Single data transfer addressing is shown in figure 2.13.

Figure 2.13 Single Data Transfer Addressing

Modulo Addressing: Like other DSPs, the SH7729R has a modulo addressing mode. Address registers are updated in the same way in this mode. When the address pointer value reaches the preset modulo end address, the address pointer value becomes the modulo start address.

Modulo addressing is only available for the X and Y data transfer instructions (MOVX.W, MOVY.W). Modulo addressing mode is specified for the X address register by setting the DMX bit in the SR register, and for the Y address register by setting the DMY bit. Modulo addressing is

www.DataSheet4U.com Rev. 5.0, 09/03, page 47 of 806

valid for either the X or the Y address register, only; it cannot be set for both at the same time. Therefore, DMX and DMY cannot both be set simultaneously.

The MOD register is provided to set the start and end addresses of the modulo address area. The MOD register contains MS (Modulo Start) and ME (Modulo End). An example of the use of the MOD register (MS and ME fields) is shown below.

| | MOV.L Mo | dAddr,Rn; | Rn=ModEnd, | ModStart |
|-----------|----------|-----------|------------|-------------|
| | LDC Rn,M | OD; | ME=ModEnd, | MS=ModStart |
| ModAddr: | .DATA.W | ModEnd | | |
| | .DATA.W | ModStart | | |
| | | | | |
| ModStart: | .DATA | | | |
| | : | | | |
| ModEnd: | .DATA | | | |

The start and end addresses are specified in MS and ME, then the DMX or DMY bit is set to 1. The address register contents are compared with ME, and if they match, start address MS is stored in the address register. The lower 16 bits of the address register are compared with ME.

The maximum modulo size is 64 kbytes. This is sufficient to access the X and Y data memory. A block diagram of modulo addressing is shown in figure 2.14.

Figure 2.14 Modulo Addressing

An example of modulo addressing is given below.

```
MS = H'7008; ME=H'700C; R4=H'A5007008;
```

DMX = 1; DMY = 0: (Modulo addressing setting for address register Ax (R4, R5))

www.DataSheet4U.com

Rev. 5.0, 09/03, page 48 of 806

As a result of the above settings, the R4 register changes as follows.

| | R4: H'A5007008 | |
|------|----------------|---|
| Inc. | R4: H'A500700A | |
| Inc. | R4: H'A500700C | |
| | R4: H'A5007008 | (Reaches modulo end address, so becomes modulo start address) |

Place the data so that the upper 16 bits of the modulo start and end addresses are the same. This is because the modulo start address overwrites only the lower 15 bits of the address register, excluding bit 0.

Note: When addition indexing is used for DSP data addressing, the address pointer may exceed the ME value without actually reaching it. In this case, the address pointer will not return to the modulo start address. Not only with modulo addressing, but when X and Y data addressing is used, bit 0 is ignored. 0 must always be written to bit 0 of the address pointer, index register, MS, and ME.

2.4.3 CPU Instruction Formats

Table 2.14 shows the instruction formats, and the meaning of the source and destination operands, for instructions executed by the CPU core. The meaning of the operands depends on the instruction code. The following symbols are used in the table.

xxxx: Instruction codemmm: Source registernnnn: Destination registeriiii: Immediate datadddd: Displacement

| Instruction Format | Source Operand | Destination Operand | Sample | Instruction |
|------------------------------|---|--|--------|-------------|
| 0 type | _ | _ | NOP | |
| 15 0 xxxx w xxxx w xxxx a | | | | |

2.4.4 DSP Instruction Formats

The SH7729R includes new instructions for digital signal processing. The new instructions are of the following two kinds.

- 1. Memory and DSP register double and single data transfer instructions (16-bit length)
- 2. Parallel processing instructions processed by the DSP unit (32-bit length)

The instruction formats are shown in figure 2.15.

Figure 2.15 DSP Instruction Formats

Double and Single Data Transfer Instructions: The format of double data transfer instructions is shown in table 2.15, and that of single data transfer instructions in table 2.16.

 Table 2.16
 Single Data Transfer Instruction Formats

Note: * Codes reserved for system use.

Parallel Processing Instructions: Parallel processing instructions are provided for efficient execution of digital signal processing using the DSP unit. They are 32 bits long and allow four simultaneous processes, an ALU operation, multiplication, and two data transfers.

Parallel processing instructions are divided into an A field and a B field. The A field defines data transfer instructions and the B field an ALU operation instruction and multiply instruction. These instructions can be defined independently, and the processing is executed in parallel, independently and simultaneously. A-field parallel data transfer instructions are shown in table 2.17, and B-field ALU operation instructions and multiply instructions in table 2.18.

2.5 Instruction Set

2.5.1 CPU Instruction Set

The SH-1/SH-2/SH-3 compatible instruction set consists of 68 basic instruction types divided into six functional groups, as shown in table 2.19. Tables 2.20 to 2.25 show the instruction notation, machine code, execution time, and function.

Table 2.19 CPU Instruction Types

| Туре | Kinds of Instruction | Op Code | Function | Number of Instructions |
|---------------------------|-------------------------|----------|---|---------------------------|
| Data transfer | 5 | MOV | Data transfer | 39 |
| instructions | | | Immediate data transfer | |
| | | | Peripheral module data transfer | |
| | | | Structure data transfer | |
| | | MOVA | Effective address transfer | - |
| | | MOVT | T bit transfer | - |
| | | SWAP | Upper/lower swap | - |
| | | XTRCT | Extraction of middle of linked registers | - |
| Arithmetic | 21 | ADD | Binary addition | 33 |
| operation | | ADDC | Binary addition with carry | - |
| operation instructions | | ADDV | Binary addition with overflow check | - |
| | | CMP/cond | Comparison | - |
| | | DIV1 | Division | - |
| | | DIV0S | Signed division initialization | - |
| | | DIV0U | Unsigned division initialization | - |
| | | DMULS | Signed double-precision multiplication | - |
| | | DMULU | Unsigned double-precision multiplication | - |
| | | DT | Decrement and test | - |
| | | EXTS | Sign extension | - |
| | | EXTU | Zero extension | - |
| | | MAC | Multiply-and-accumulate, double- precision multiply-and-accumulate | - |
| | | MUL | Double-precision multiplication $(32 \times 32 \text{ bits})$ | - |

| Туре | Kinds of pe Instruction | | Op Code Function | | |
|---|----------------------------|-------|--|----|--|
| Arithmetic operation instructions | 21 | MULS | Signed multiplication (16×16 bits) | 33 | |
| | | MULU | Unsigned multiplication (16×16 bits) | | |
| | | NEG | Sign inversion | | |
| www.DataSheet4U.com | | NEGC | Sign inversion with borrow | | |
| | | SUB | Binary subtraction | | |
| | | SUBC | Binary subtraction with carry | _ | |
| | | SUBV | Binary subtraction with underflow | | |
| Logic | 6 | AND | Logical AND | 14 | |
| operation instructions | | NOT | Bit inversion | | |
| Instructions | | OR | Logical OR | | |
| | | TAS | Memory test and bit setting | | |
| | | TST | Logical AND and T bit setting | | |
| | | XOR | Exclusive logical OR | | |
| Shift instructions | 12 | ROTL | 1-bit left shift | 16 | |
| | | ROTR | 1-bit right shift | | |
| | | ROTCL | 1-bit left shift with T bit | | |
| | | ROTCR | 1-bit right shift with T bit | | |
| | | SHAL | Arithmetic 1-bit left shift | | |
| | | SHAR | Arithmetic 1-bit right shift | | |
| | | SHLL | Logical 1-bit left shift | | |
| | | SHLLn | Logical n-bit left shift | | |
| | | SHLR | Logical 1-bit right shift | | |
| | | SHLRn | Logical n-bit right shift | | |
| | | SHAD | Arithmetic dynamic shift | | |
| | | SHLD | Logical dynamic shift | | |

| Туре | Kinds of Instruction | Op Code | Function | Number of Instructions | |
|-------------------------|-------------------------|---------|--|---------------------------|--|
| Branch instructions | 9 | BF | Conditional branch, delayed conditional branch $(T = 0)$ | 11 | |
| | | BT | Conditional branch, delayed conditional branch (T = 1) | - | |
| www.DataSheet4U.com | | BRA | Unconditional branch | - - - | |
| | | BRAF | Unconditional branch | | |
| | | BSR | Branch to subroutine procedure | | |
| | | BSRF | Branch to subroutine procedure | | |
| | | JMP | Unconditional branch | = | |
| | | JSR | Branch to subroutine procedure | = | |
| | | RTS | Return from subroutine procedure | _ | |
| System | 15 | CLRT | T bit clear | 75 | |
| control instructions | | CLRMAC | MAC register clear | = | |
| | | CLRS | S bit clear | - | |
| | | LDC | Load into control register | | |
| | | LDS | Load into system register | - | |
| | | LDTLB | PTEH/PTEL load into TLB | - | |
| | | NOP | No operation | - | |
| | | PREF | Data prefetch to cache | - | |
| | | RTE | Return from exception handling | | |
| | | SETS | S bit setting | | |
| | | SETT | T bit setting | _ | |
| | | SLEEP | Transition to power-down mode | - | |
| | | STC | Store from control register | _ | |
| | | STS | Store from system register | _ | |
| | | TRAPA | Trap exception handling | | |
| Total: | 68 | | | 188 | |

The instruction code, operation, and number of execution states of the CPU instructions are shown in the following tables, classified by instruction type, using the format shown below.

| Instruction | Instruction Code | Operation | Privilege | Execution States | T Bit |
|---|---|--|-------------------------------------|--|---|
| Indicated by mnemonic. www.DataShee | Indicated in MSB \leftrightarrow LSB order. | Indicates summary of operation. | Indicates a privileged instruction. | Value whe no wait states are inserted ^{*1} | n Value of T bit after instruction is executed |
| Explanation of Symbols | Explanation of Symbols | Explanation of Symbols | | | Explanation of Symbols |
| OP.Sz SRC, DEST OP: Operation code Sz: Size SRC: Source DEST: Destination | mmmm: Source register nnnn: Destination register 0000: R0 0001: R1 | →, ←: Transfer direction (xx): Memory operand M/Q/T: Flag bits in SR &: Logical AND of each bit | | | -: No change |
| Rm: Source register | 1111: R15 iiii: Immediate data dddd: Displacement ^{*2} | Logical OR of each bit Exclusive logical OR of each bit | | | |
| Rn: Destination register imm: Immediate data | | | | | |
| disp: Displacement | | ~: Logical NOT of each bit | | | |
| | | < <n: left="" n-bit="" shift<="" td=""><td></td><td></td><td></td></n:> | | | |
| | | >>n: n-bit right shift | | | |

Notes: 1. The table shows the minimum number of execution states. In practice, the number of instruction execution states will be increased in cases such as the following:

- (1) When there is contention between an instruction fetch and a data access
- (2) When the destination register of a load instruction (memory \rightarrow register) is also used by the following instruction
- 2. Scaled (x1, x2, or x4) according to the instruction operand size, etc.

Note: * Number of states before the chip enters the sleep state.

The table shows the minimum number of clocks required for execution. In practice, the number of execution cycles will be increased if there is contention between an instruction fetch and a data access, or if the destination register of a load instruction (memory \rightarrow register) is also used by the following instruction.

2.6 DSP Extended-Function Instructions

2.6.1 Introduction

The DSP extended-function instructions are classified into the following three groups:

- 1. Additional system control instructions for the CPU unit (section 2.6.2, Added CPU System Control Instructions)
- 2. DSP unit memory-register single and double data transfer (section 2.6.3, Single and Double Data Transfer for DSP Data Instructions)
- 3. DSP unit parallel processing (section 2.6.4, DSP Operation Instruction Set)

2.6.2 Added CPU System Control Instructions

The instructions in this class are treated as part of the CPU core functions, and therefore all the added instructions have a 16-bit code length. All the additional instructions belong to the system control instruction group. Table 2.26 summarizes the added system instructions.

Control registers—RS, RE, and MOD—have been added to the CPU core to support loop control and modulo addressing functions, and LDC and STS instructions have been provided for these registers.

The DSP engine's DSR, A0, X0, X1, Y0, and Y1 registers are treated as system registers such as STS and LDS instructions are supported for these registers. As digital signal processing operations usually employ a multi-level nested-loop structure, DSP performance can be improved by means of a zero-overhead loop control function. SETRC instructions are provided to set the repeat count in the RC field in SR[27:16]. When an immediate operand type SETRC instruction is executed, the 8-bit immediate operand data is set in SR[23:16], and 0 is set in the remaining bits, SR[27:24]. When a register operand type SETRC instruction is executed, Rn[11:0] is set in SR[27:16]. The start address and end address of the repeat loop are set in the RS register and RE register. There are two ways of setting the addresses: by using an LDC instruction, or by using the LDRS and LDRE instructions.

2.6.3 Single and Double Data Transfer for DSP Data Instructions

The instructions in this class are provided to reduce the program code size for DSP operations. All the new instructions in this class have a 16-bit code length. Instructions in this class are divided into two groups: single data transfer instructions and double data transfer instructions. The operand flexibility of the double data transfer instructions is the same as with the A field in parallel instruction class data transfer instructions described in section 2.6.4, DSP Operation Instructions Set. However, conditional load instructions cannot be used with these 16-bit instructions. In single transfer, the Ax pointer and two address pointers (R2 and R3) are used as the As pointer, but the Ay pointer is not used. Tables 2.27 and 2.28 list the single and double data transfer instructions.

With double data transfer group instructions, X memory and Y memory can be accessed in parallel. The Ax pointer can only be used by X memory access instructions, and the Ay pointer only by Y memory access instructions. Double data transfer instructions can only access the onchip X and Y memory areas. Single data transfer instructions use a 16-bit instruction code, and can access any memory address space.

Rn (n = 2 to 7) registers are normally used as the Ax, Ay, and As pointers. The pointer names themselves can be changed with the assembler rename function. The following renaming scheme is recommended.

R2:As2, R3:As3, R4:Ax0 (As0), R5:Ax1 (As1), R6:Ay0, R7:Ay1, R8:Ix(Is), R9:Iy

Table 2.28 Single Data Transfer Instructions

Note: * If guard bit registers A0G and A1G are specified in source operand Ds, the data is output to the LDB[7:0] bus and the sign bit is copied into the upper bits, [31:8].

The correspondence between DSP data transfer operands and registers is shown in table 2.29. CPU core registers are used as a pointer address that indicates a memory address.

| I | Register | Ax | Ix | Dx | Ay | ly | Dy | Da | As | ls | Ds |

 Table 2.29
 Correspondence between DSP Data Transfer Operands and Registers

2.6.4 DSP Operation Instruction Set

DSP operation instructions are instructions for digital signal processing performed by the DSP unit. These instructions have a 32-bit instruction code, and multiple instructions can be executed in parallel. The instruction code is divided into an A field and B field; a double data transfer instruction is specified in the A field, and a single or double data operation instruction in the B field. Instructions can be specified independently, and are also executed independently. The function of the A field—that is, the data transfer instruction field—is basically the same as in the double data transfer instructions described in section 2.6.3, Single and Double Data Transfer for DSP Data Instructions, but has a special function in load instructions.

B-field data operation instructions are of three kinds: double data operation instructions, conditional single data operation instructions, and unconditional single data operation instructions. The formats of the DSP operation instructions are shown in table 2.30. The respective operands are selected independently from the DSP registers. The correspondence between DSP operation instruction operands and registers is shown in table 2.31.

| Туре | | Instru | ction For | mats | | Instructions |

 Table 2.31
 Correspondence between DSP Instruction Operands and Registers

When writing parallel instructions, the B-field instruction is written first, followed by the A-field instruction. A sample parallel processing program is shown in figure 2.16.

```
        PADD A0, M0, A0
        PMULS X0, Y0, M0
        MOVX.W @R4+, X0
        MOVY.W @R6+, Y0 [;]

        DCF
        PINC X1, A1
        MOVX.W A0, @R5+R8
        MOVY.W @R7+, Y0 [;]

        PCMP X1, M0
        MOVX.W @R4+, X0
        [NOPY] [;]
```

Figure 2.16 Sample Parallel Instruction Program

Square brackets mean that the contents can be omitted.

The no operation instructions NOPX and NOPY can be omitted. Table 2.32 gives an overview of the B field in parallel operation instructions.

A semicolon is the instruction line delimiter, but this can also be omitted. If the semicolon delimiter is used, the area to the right of the semicolon can be used as a comment field. This has the same function as with conventional SH tools.

The DSR register condition code bit (DC) is updated on the basis of the result of an unconditional ALU or shift operation instruction. Conditional instructions do not update the DC bit. Multiply instructions, also, do not update the DC bit. The DC bit updating conditions are determined by bits CS0 to CS2 in the DSR register. The DC bit update rules are shown in table 2.33.

| Instr | uction | Instruction Code | Operation | Execu- tion States | DC |

| CS | 6 [2: | :0] | Condition Mode | Description |
|----|-------|-----|----------------------------------|--|
| 0 | 0 | 0 | Carry or borrow mode | The DC bit is set if an ALU arithmetic operation generates a carry or borrow, and is cleared otherwise. |
| | | WWV | w.DataSheet4U.c | When a shift instruction (PSHA or PSHL) is executed, the last bit data shifted out is copied into the DC bit. |
| | | | | When an ALU logical operation is executed, the DC bit is always cleared. |
| 0 | 0 | 1 | Negative value mode | When an ALU arithmetic operation or arithmetic shift (PSHA) operation is executed, the MSB of the result, including the guard bits, is copied into the DC bit. |
| | | | | When an ALU logical operation or logical shift (PSHL) operation is executed, the MSB of the result, excluding the guard bits, is copied into the DC bit. |
| 0 | 1 | 0 | Zero value mode | The DC bit is set if the result of an ALU arithmetic or shift operation is all-zeros, and is cleared otherwise. |
| 0 | 1 | 1 | Overflow mode | The DC bit is set if the result of an ALU arithmetic operation or arithmetic shift (PSHA) operation exceeds the destination register range, excluding the guard bits, and is cleared otherwise. |
| | | | | When an ALU logical operation or logical shift (PSHL) operation is executed, the DC bit is always cleared. |
| 1 | 0 | 0 | Signed greater-than mode | This mode is similar to signed greater-or-equal mode, but DC is cleared if the result is all-zeros. |
| | | | | DC = ~{(negative value ^ over-range) zero value}; In case of arithmetic operation |
| | | | | DC = 0; In case of logical operation |
| 1 | 0 | 1 | Signed greater-or- equal mode | If the result of an ALU arithmetic operation or arithmetic shift (PSHA) operation exceeds the destination register range, including the guard bits (ioverrangeî), the definition is the same as in negative value mode. If the result is not over-range, the definition is the negative value mode with the DC bit inverted. |
| | | | | When an ALU logical operation or logical shift (PSHL) operation is executed, the DC bit is always cleared. |
| | | | | DC = ~(negative value ^ over-range); In case of arithmetic operation |
| | | | | DC = 0 ; In case of logical operation |
| 1 | 1 | 0 | Reserved | |
| 1 | 1 | 1 | Reserved | |

Table 2.33 DC Bit Update Definitions

Conditional Operations and Data Transfer: Some DSP instruction can be executed conditionally, as described earlier. The specified condition is valid only for the B field of the instruction, and is not valid for data transfer instructions for which a parallel specification is made. Examples are shown in figure 2.17.

```
WDCT PADD X0, Y0, A0 MOVX.W @R4+, X0 MOVY.W A0, @R6+R9;
 When condition is True
 Before execution: X0=H'33333333, Y0=H'55555555, A0=H'123456789A,
               R4=H'00008000, R6=H'00008233, R9=H'00000004
                (R4) = H'1111, (R6) = H'2222
 After execution:
               X0=H'11110000, Y0=H'55555555, A0=H'FF888888888,
               R4=H'00008002, R6=H'00008237, R9=H'00000004
                (R4)=H'1111, (R6)=H'3456
 When condition is False
 Before execution: x0=H'33333333, Y0=H'55555555, A0=H'123456789A,
               R4=H'00008000, R6=H'00008233, R9=H'00000004
               (R4)=H'1111, (R6)=H'2222
 After execution:
               X0=H'11110000, Y0=H'55555555, A0=H'123456789A,
               R4=H'00008002, R6=H'00008237, R9=H'00000004
                (R4)=H'1111, (R6)=H'3456
```

Figure 2.17 Examples of Conditional Operations and Data Transfer Instructions

Assignment of NOPX and NOPY Instruction Codes: When there is no data transfer instruction to be parallel-processed simultaneously with a DSP operation instruction, an NOPX or NOPY instruction can be written as the data transfer instruction, or the instruction can be omitted. The instruction code is the same whether an NOPX or NOPY instruction is written or the instruction is omitted. Examples of NOPX and NOPY instruction codes are shown in table 2.34.

Section 3 Memory Management Unit (MMU)

3.1 Overview

3.1.1 wwwFeatureset4U.com

The SH7729R has an on-chip memory management unit (MMU) that implements address translation. The SH7729R features a resident translation look-aside buffer (TLB) that caches information for user-created address translation tables located in external memory. It enables high-speed translation of virtual addresses into physical addresses. Address translation uses the paging system and supports two page sizes (1 kbyte and 4 kbytes). The access right to virtual address space can be set for privileged and user modes to provide memory protection.

3.1.2 Role of MMU

The MMU is a feature designed to make efficient use of physical memory. As shown in figure 3.1, if a process is smaller in size than the physical memory, the entire process can be mapped onto physical memory. However, if the process increases in size to the extent that it no longer fits into physical memory, it becomes necessary to partition the process and to map those parts requiring execution onto memory as occasion demands (1). Having the process itself consider this mapping onto physical memory would impose a large burden on the process. To lighten this burden, the idea of virtual memory was born as a means of performing en bloc mapping onto physical memory (2). In a virtual memory system, substantially more virtual memory than physical memory is provided, and the process is mapped onto this virtual memory. Thus a process only has to consider operation in virtual memory. Mapping from virtual memory to physical memory is handled by the MMU. The MMU is normally controlled by the operating system, switching physical memory to allow the virtual memory required by a process to be mapped onto physical memory in a smooth fashion. Switching of physical memory is carried out via secondary storage, etc.

The virtual memory system that came into being in this way is particularly effective in a timesharing system (TSS) in which a number of processes are running simultaneously (3). If processes running in a TSS had to take mapping onto virtual memory into consideration while running, it would not be possible to increase efficiency. Virtual memory is thus used to reduce this load on the individual processes and so improve efficiency (4). In the virtual memory system, virtual memory is allocated to each process. The task of the MMU is to perform efficient mapping of these virtual memory areas onto physical memory. It also has a memory protection feature that prevents one process from inadvertently accessing another process's physical memory.

When address translation from virtual memory to physical memory is performed using the MMU, it may occur that the relevant translation information is not recorded in the MMU, with the result that one process may inadvertently access the virtual memory allocated to another process the translation information.

Rev. 5.0, 09/03, page 91 of 806

case, the MMU will generate an exception, change the physical memory mapping, and record the new address translation information.

Although the functions of the MMU could also be implemented by software alone, the need for translation to be performed by software each time a process accesses physical memory would result in poor efficiency. For this reason, a buffer for address translation (translation look-aside buffer: TLB) is provided in hardware to hold frequently used address translation information. The TLB can be described as a cache for storing address translation information. Unlike cache memory, however, if address translation fails, that is, if an exception is generated, switching of address translation information is normally performed by software. This makes it possible for memory management to be performed flexibly by software.

The MMU has two methods of mapping from virtual memory to physical memory: a paging method using fixed-length address translation, and a segment method using variable-length address translation. With the paging method, the unit of translation is a fixed-size address space (usually of 1 to 64 kbytes) called a page. This LSI uses the paging method.

In the following text, the SH7729R address space in virtual memory is referred to as virtual address space, and address space in physical memory as physical memory space.

Figure 3.1 MMU Functions

3.1.3 SH7729R MMU

Virtual Address Space: The SH7729R uses 32-bit virtual addresses to access a 4-Gbyte virtual address space that is divided into several areas. Address space mapping is shown in figure 3.2.

(a) Privileged Mode

ww.DataSheet4U.com

In privileged mode, there are five areas, P0–P4. The P0 and P3 areas are mapped onto physical address space in page units, in accordance with address translation table information. Write-back or write-through can be selected for write access by means of a cache control register (CCR) setting.

Mapping of the P1 area is fixed in physical address space (H'00000000 to H'1FFFFFFF). In the P1 area, setting a virtual address MSB (bit 31) to 0 generates the corresponding physical address. P1 area accesses can be cached, and the cache control register (CCR) is set to indicate whether to cache or not. Write-back or write-through mode can be selected.

Mapping of the P2 area is fixed in physical address space (H'00000000 to H'1FFFFFFF). In the P2 area, setting the top three virtual address bits (bits 31, 30, and 29) to 0 generates the corresponding physical address. P2 area access cannot be cached.

The P1 and P2 areas are not mapped by the address translation table, so the TLB is not used and no exceptions such as TLB misses occur. Initialization of MMU control registers, exception handling routines, and the like should be located in the P1 and P2 areas. Routines that require high-speed processing should be placed in the P1 area, since it can be cached.

Some peripheral module control registers are located in area 1 of the physical address space. When the physical address space is not used for address translation, these registers should be located in the P2 area. When address translation is to be used, set no caching.

The P4 area is used for mapping peripheral module register addresses, etc.

(b) User Mode

In user mode, 2 Gbytes of the virtual address space from H'00000000 to H'7FFFFFFF (area U0) can be accessed. U0 is mapped onto physical address space in page units, in accordance with address translation table information. When the DSP bit in CPU status register (SR) is off, 2 Gbytes of the virtual address space from H'80000000 to H'FFFFFFFF cannot be accessed in the user mode. Attempting to do so creates an address error. Write-back or write-through mode can be selected for write accesses by means of a cache control register (CCR) setting. When the DSP bit in CPU status register (SR) is on, a new 16-Mbyte address space, Uxy, is defined from address H'A5000000 to H'A5FFFFF for X/Y RAM. This Uxy space is non-cached, fixed physical address space. Any access to address space beyond U0 and Uxy creates an address error. For details of the X/Y RAM space, refer to section 6, X/Y Memory.

www.DataSheet4U.com

Figure 3.2 Virtual Address Space Mapping

Physical Address Space: The SH7729R supports a 32-bit physical address space, but the upper 3 bits are actually ignored and treated as a shadow. See section 11, Bus State Controller (BSC), for details.

Address Translation: When the MMU is enabled, the virtual address space is divided into units called pages. Physical addresses are translated in page units. Address translation tables in external memory hold information such as the physical address that corresponds to the virtual address and memory protection codes. When an access to an area other than P4 occurs, if the accessed virtual address belongs to area P1 or P2 there is no TLB access and the physical address is uniquely defined. If it belongs to area P0, P3, or U0, the TLB is searched by virtual address and, if that virtual address is registered in the TLB, the access hits the TLB. The corresponding physical address and the page control information are read from the TLB and the physical address is determined.

www.DataSheet4U.com Rev. 5.0, 09/03, page 95 of 806

If the virtual address is not registered in the TLB, a TLB miss exception occurs and processing will shift to the TLB miss handler. In the TLB miss handler, the TLB address translation table in external memory is searched and the corresponding physical address and the page control information are registered in the TLB. After returning from the handler, the instruction that caused the TLB miss is re-executed. When the MMU is enabled, address translation information that results in a physical address space of H'80000000–H'FFFFFFF should not be registered in the TLB.

When the MMU is disabled, the virtual address is used directly as the physical address. As the SH7729R supports a 29-bit address space as the physical address space, the top 3 bits of the physical address are ignored, and constitute a shadow space (see section 11, Bus State Controller (BSC)). For example, addresses H'00001000 in the P0 area, H'80001000 in the P1 area, H'A0001000 in the P2 area, and H'C0001000 in the P3 area are all mapped onto the same physical address. When access to these addresses is performed with the cache enabled, an address with the top 3 bits of the physical address masked to 0 is stored in the cache address array to ensure data congruity.

Single Virtual Memory Mode and Multiple Virtual Memory Mode: There are two virtual memory modes: single virtual memory mode and multiple virtual memory mode. In single virtual memory mode, multiple processes run in parallel using the virtual address space exclusively and the physical address corresponding to a given virtual address is specified uniquely. In multiple virtual memory mode, multiple processes run in parallel sharing the virtual address space, so a given virtual address may be translated into different physical addresses depending on the process. Single or multiple virtual mode is selected by a value set in the MMU control register (MMUCR). In terms of operation, the only difference between single virtual memory mode and multiple virtual memory mode is in the TLB address comparison method (see section 3.3.3, TLB Address Comparison).

Address Space Identifier (ASID): In multiple virtual memory mode, the address space identifier (ASID) is used to differentiate between processes running in parallel and sharing virtual address space. The ASID is 8 bits in length and can be set by software setting of the ASID of the currently running process in the page table entry register high (PTEH) within the MMU. When the process is switched using the ASID, the TLB does not have to be purged.

In single virtual memory mode, the ASID is used to provide memory protection for processes running simultaneously and using the virtual address space exclusively (see section 3.4.2, MMU Software Management).

www.DataSheet4U.com

3.1.4 **Register Configuration**

Table 3.1 shows the configuration of the MMU control registers.

| Name www.DataSheet4U.com | Abbreviation | R/W | Size | Initial Value ^{*1} | Address | | | |
|--|--------------|-----|----------|-----------------------------|------------|--|--|--|
| Page table entry register high | PTEH | R/W | Longword | Undefined | H'FFFFFF0 | | | |
| Page table entry register low | PTEL | R/W | Longword | Undefined | H'FFFFFFF4 | | | |
| Translation table base register | ТТВ | R/W | Longword | Undefined | H'FFFFFF8 | | | |
| TLB exception address register | TEA | R/W | Longword | Undefined | H'FFFFFFC | | | |
| MMU control register | MMUCR | R/W | Longword | *2 | H'FFFFFE0 | | | |
| Notes: 1. Initialized by a power-on reset or manual reset. | | | | | | | | |

Table 3.1 **Register Configuration**

SV bit: Undefined

Other bits: 0

3.2 **Register Description**

There are five registers for MMU processing. These registers are located in address space area P4 and can only be accessed from privileged mode by specifying the address.

- 1. The page table entry register high (PTEH) register residing at address H'FFFFFF0, which consists of a virtual page number (VPN) and ASID. The VPN set is the VPN of the virtual address at which the exception is generated in case of an MMU exception or address error exception. When the page size is 4 kbytes, the VPN is the upper 20 bits of the virtual address, but in this case the upper 22 bits of the virtual address are set. The VPN can also be modified by software. As the ASID, software sets the number of the currently executing process. The VPN and ASID are recorded in the TLB by the LDTLB instruction.
- 2. The page table entry register low (PTEL) register residing at address H'FFFFFF4, and used to store the physical page number and page management information to be recorded in the TLB by the LDTLB instruction. The contents of this register are only modified in response to a software command. (Refer to section 3.4.3, MMU Instruction (LDTLB), and section 3.5, MMU Exceptions.)
- 3. The translation table base register (TTB) residing at address H'FFFFFF8, which points to the base address of the current page table. The software does not set any value in TTB automatically. TTB is available to software for general purposes.
- 4. The TLB exception address register (TEA) residing at address H'FFFFFFC, which stores the virtual address corresponding to a TLB or address error exception. This value remains valid until the next exception or interrupt.

5. The MMU control register (MMUCR) residing at address H'FFFFFE0, which makes the MMU settings described in figure 3.3. Any program that modifies MMUCR should reside in the P1 or P2 area.

The MMU registers are shown in figure 3.3.

Figure 3.3 MMU Register Contents

3.3 TLB Functions

3.3.1 Configuration of the TLB

The TLB caches address translation table information located in external memory. The address translation table stores the physical page number translated from the virtual page number and the control information for the page, which is the unit of address translation. Figure 3.4 shows the overall TLB configuration. The TLB is 4-way set associative with 128 entries. There are 32 entries for each way. Figure 3.5 shows the configuration of virtual addresses and TLB entries.

Figure 3.4 Overall Configuration of the TLB

| | | | | | | | | |
| | | | | | | | | |

Figure 3.5 Virtual Address and TLB Structure

3.3.2 TLB Indexing

The TLB uses a 4-way set associative scheme, so entries must be selected by index. VPN bits 16 to 12 and ASID bits 4 to 0 in PTEH are used as the index number. The index number can be generated in two different ways depending on the setting of the IX bit in MMUCR.

- 1. When IX = 0, VPN bits 16–12 alone are used as the index number
- 2. When IX = 1, VPN bits 16–12 are EX-ORed with ASID bits 4–0 to generate the index number

The second method is used to prevent lowered TLB efficiency that results when multiple processes run simultaneously in the same virtual address space (multiple virtual memory) and a specific entry is selected by generating an index number for each process. Figures 3.6 and 3.7 show the indexing schemes.

Figure 3.6 TLB Indexing (IX = 1)

Figure 3.7 TLB Indexing (IX = 0)

3.3.3 TLB Address Comparison

A TLB address comparison is performed when an instruction is fetched from a program in external memory or data in external memory is referenced. The items used in the comparison are VPN and ASID. The VPN of the virtual address that accesses external memory is compared to the VPN of the TLB entry selected with the index number. The ASID within the PTEH is compared to the ASID of the indexed TLB entry. All four ways are searched simultaneously. If the compared values match, and the indexed TLB entry is valid (V bit = 1), the hit is registered.

It is necessary to have software ensure that TLB hits do not occur simultaneously in more than one way, as hardware operation is not guaranteed if this occurs. For example, if there are two identical TLB entries with the same VPN and a setting is made such that a TLB hit is made only by a process with ASID = H'FF when one is in the shared state (SH = 1) and the other in the non-shared state (SH = 0), then if the ASID in PTEH is set to H'FF, there is a possibility of simultaneous TLB hits in both these ways. It is therefore necessary to ensure that this kind of setting is not made by software.

The object compared varies depending on the page management information (SZ, SH) in the TLB entry. It also varies depending on whether the system supports multiple virtual memory or single virtual memory.

The page-size information determines whether VPN (11–10) is compared. VPN (11–10) is compared for 1-kbyte pages (SZ = 0) but not for 4-kbyte pages (SZ = 1).

The sharing information (SH) determines whether PTEH.ASID and the ASID in the TLB entry are compared. ASIDs are compared when there is no sharing between processes (SH = 0) but not when there is sharing (SH = 1).

When single virtual memory is supported (MMUCR.SV = 1) and privileged mode is engaged (SR.MD = 1), all process resources can be accessed. This means that ASIDs are not compared when single virtual memory is supported and privileged mode is engaged. The objects of address comparison are shown in figure 3.8.

Figure 3.8 Objects of Address Comparison

3.3.4 Page Management Information

In addition to the SH and SZ bits, the page management information of TLB entries also includes D, C, and PR bits.

The D bit of a TLB entry indicates whether the page is dirty (i.e., has been written to). If the D bit is 0, an attempt to write to the page results in an initial page write exception. For physical page swapping between secondary memory and main memory, for example, pages are controlled so that a dirty page is paged out of main memory only after that page is written back to secondary memory. To record that there has been a write to a given page in the address translation table in memory, an initial page write exception is used.

The C bit in the entry indicates whether the referenced page resides in a cacheable or noncacheable area of memory. When the control register in area 1 is mapped, set the C bit to 0.

The PR field specifies the access rights for the page in privileged and user modes and is used to protect memory. Attempts at nonpermitted accesses result in TLB protection violation exceptions.

Access states designated by the D, C, and PR bits are shown in table 3.2.

| | | Privi | leged Mode | User Mode | | | |
|--------|--|-----------------------------|---------------------------------------|--|---------------------------------------|--|--|
| | | Reading | Writing | Reading | Writing | | |
| D bit | 0 | Permitted | Initial page write exception | Permitted | Initial page write exception | | |
| | 1 | Permitted | Permitted | Permitted | Permitted | | |
| C bit | C bit 0 Permitted Permitted (no caching) (no caching) | | Permitted (no caching) | Permitted (no caching) | | | |
| | 1 | Permitted (with caching) | Permitted (with caching) | Permitted (with caching) | Permitted (with caching) | | |
| PR bit | 00 | Permitted | TLB protection violation exception | TLB protection violation exception | TLB protection violation exception | | |
| | 01 | Permitted | Permitted | TLB protection violation exception | TLB protection violation exception | | |
| | 10 | Permitted | TLB protection violation exception | Permitted | TLB protection violation exception | | |
| | 11 | Permitted | Permitted | Permitted | Permitted | | |

Table 3.2 Access States Designated by D, C, and PR Bits

3.4 MMU Functions

3.4.1 MMU Hardware Management

There are two kinds of MMU hardware management as follows:

- 1. The MMU decodes the virtual address accessed by a process and performs address translation by controlling the TLB in accordance with the MMUCR settings.
- 2. In address translation, the MMU receives page management information from the TLB, and determines the MMU exception and whether the cache is to be accessed (using the C bit). For details of the determination method and the hardware processing, see section 3.5, MMU Exceptions.

3.4.2 MMU Software Management

There are three kinds of MMU software management, as follows.

- MMU register setting. MMUCR setting, in particular, should be performed in areas P1 and P2 for which address translation is not performed. Also, since SV and IX bit changes constitute address translation system changes, in this case, TLB flushing should be performed by simultaneously writing 1 to the TF bit also. Since MMU exceptions are not generated in the MMU disabled state with the AT bit cleared to 0, use in the disabled state must be avoided with software that does not use the MMU.
- TLB entry recording, deletion, and reading. TLB entry recording can be done in two ways: by using the LDTLB instruction, or by writing directly to the memory-mapped TLB. For TLB entry deletion and reading, the memory-mapped TLB can be accessed. See section 3.4.3, MMU Instruction (LDTLB), for details of the LDTLB instruction, and section 3.6, Memory-Mapped TLB, for details of the memory-mapped TLB.
- 3. MMU exception handling. When an MMU exception is generated, it is handled on the basis of information set from the hardware side. See section 3.5, MMU Exceptions, for details.

When single virtual memory mode is used, it is possible to create a state in which physical memory access is enabled in privileged mode only by clearing the share status bit (SH) to 0 to specify recording of all TLB entries. This strengthens inter-process memory protection, and enables special access levels to be created in privileged mode only.

Recording a 1-kbyte page TLB entry may result in a synonym problem. See section 3.4.4, Avoiding Synonym Problems.

www.DataSheet4U.com Rev. 5.0, 09/03, page 105 of 806

3.4.3 MMU Instruction (LDTLB)

The load TLB instruction (LDTLB) is used to record TLB entries. When the IX bit in MMUCR is 0, the LDTLB instruction changes the TLB entry in the way specified by the RC bit in MMUCR to the value specified by PTEH and PTEL, using VPN bits 16–12 specified in PTEH as the index number. When the IX bit in MMUCR is 1, the EX-OR of VPN bits 16–12 specified in PTEH and ASID bits 4–0 in PTEH is used as the index number.

Figure 3.9 shows the case where the IX bit in MMUCR is 0.

When an MMU exception occurs, the virtual page number of the virtual address that caused the exception is set in PTEH by hardware. The way is set in the RC bit of MMUCR for each exception (see figure 3.3). Consequently, if the LDTLB instruction is issued after setting only PTEL in the MMU exception handling routine, TLB entry recording is possible. Any TLB entry can be updated by software rewriting of PTEH and the RC bits in MMUCR.

As the LDTLB instruction changes address translation information, there is a risk of destroying address translation information if this instruction is issued in the P0, U0, or P3 area. Make sure, therefore, that this instruction is issued in the P1 or P2 area. Also, an instruction associated with an access to the P0, U0, or P3 area (such as the RTE instruction) should be issued at least two instructions after the LDTLB instruction.

Figure 3.9 Operation of LDTLB Instruction

3.4.4 Avoiding Synonym Problems

When a 1-kbyte page is recorded in a TLB entry, a synonym problem may arise. If a number of virtual addresses are mapped onto a single physical address, the same physical address data will be recorded in a number of cache entries, and it will not be possible to guarantee data congruity. The reason why this problem only occurs when using a 1-kbyte page is explained below with reference to figure 3.10.

To achieve high-speed operation of the SH7729R cache, an index number is created using virtual address bits 11–4. When a 4-kbyte page is used, virtual address bits 11–4 are included in the offset, and since they are not subject to address translation, they are the same as physical address bits 11–4. In cache-based address comparison and recording in the address array, since the cache tag address is a physical address, physical address bits 28–10 are recorded.

When a 1-kbyte page is used, also, a cache index number is created using virtual address bits 11-4. However, in case of a 1-kbyte page, virtual address bits 11 and 10 are subject to address translation and therefore may not be the same as physical address bits 11 and 10. Consequently, the physical address is recorded in a different entry from that of the index number indicated by the physical address in the cache address array.

www.DataSheet4U.com Rev. 5.0, 09/03, page 107 of 806

Note: When multiple address information items use the same physical memory to provide for future expansion of the SuperH RISC engine family, it is recommended that VPN[20:10] be made equal. Also, the same physical addresses should not be used with different page size address conversion information.

For example, assume that, with 1-kbyte page TLB entries, TLB entries for which the following translation has been performed are recorded in two TLBs:

Virtual address 1 H'00000000 \rightarrow physical address H'00000C00 Virtual address 2 H'00000C00 \rightarrow physical address H'00000C00

Virtual address 1 is recorded in cache entry H'00, and virtual address 2 in cache entry H'C0. Since two virtual addresses are recorded in different cache entries despite the fact that the physical addresses are the same, memory inconsistency will occur as soon as a write is performed to either virtual address. Therefore, when recording a 1-kbyte TLB entry, if the physical address is the same as a physical address already used in another TLB entry, it should be recorded in such a way that physical address bits 11 and 10 are the same.

3.5 MMU Exceptions

There are four MMU exceptions: TLB miss, TLB protection violation, TLB invalid, and initial page write.

3.5.1 TLB Miss Exception

A TLB miss exception occurs when the virtual address and the address array of the selected TLB entry are compared and no match is found. TLB miss exception handling includes both hardware and software operations.

Hardware Operations: In a TLB miss, the SH7729R hardware executes a set of prescribed operations, as follows:

- 1. The VPN field of the virtual address causing the exception is written to the PTEH register.
- 2. The virtual address causing the exception is written to the TEA register.
- 3. Either exception code H'040 for a load access, or H'060 for a store access, is written to the EXPEVT register.
- 4. The PC value indicating the address of the instruction in which the exception occurred is written to the saved program counter (SPC). If the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written to SPC.
- 5. The contents of the status register (SR) at the time of the exception are written to the saved status register (SSR).
- 6. The mode (MD) bit in SR is set to 1 to place the SH7729R in privileged mode.
- 7. The block (BL) bit in SR is set to 1 to mask any further exception requests.
- 8. The register bank (RB) bit in SR is set to 1.
- 9. The random counter (RC) field in the MMU control register (MMUCR) is incremented by 1 when all ways are checked for the TLB entry corresponding to the virtual address at which the exception occurred, and all ways are valid. If one or more ways are invalid, those ways are set in RC in prioritized order from way 0 through way 1, way 2, and way 3.
- 10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000400 to invoke the user-written TLB miss exception handler.

Software (TLB Miss Handler) Operations: The software searches the page tables in external memory and allocates the required page table entry. Upon retrieving the required page table entry, software must execute the following operations:

1. Write the value of the physical page number (PPN) field and the protection key (PR), page size (SZ), cacheable (C), dirty (D), share status (SH), and valid (V) bits of the page table entry recorded in the address translation table in external memory into the PTEL register in the SH7729R.

- 2. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
- 3. Issue an LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
- 4. Issue an RTE (return from exception handler) instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

/ww.DataSheet4U.com

3.5.2 TLB Protection Violation Exception

A TLB protection violation exception occurs when the virtual address and the address array of the selected TLB entry are compared and a valid entry is found to match, but the type of access is not permitted by the access rights specified in the PR field. TLB protection violation exception handling includes both hardware and software operations.

Hardware Operations: In a TLB protection violation exception, the SH7729R hardware executes a set of prescribed operations, as follows:

- 1. The VPN field of the virtual address causing the exception is written to the PTEH register.
- 2. The virtual address causing the exception is written to the TEA register.
- 3. Either exception code H'0A0 for a load access, or H'0C0 for a store access, is written to the EXPEVT register.
- 4. The PC value indicating the address of the instruction in which the exception occurred is written into SPC (if the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written into SPC).
- 5. The contents of SR at the time of the exception are written to SSR.
- 6. The MD bit in SR is set to 1 to place the SH7729R in privileged mode.
- 7. The BL bit in SR is set to 1 to mask any further exception requests.
- 8. The register bank (RB) bit in SR is set to 1.
- 9. The way that generated the exception is set in the RC field in MMUCR.
- 10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100 to invoke the TLB protection violation exception handler.

Software (TLB Protection Violation Handler) Operations: Software resolves the TLB protection violation and issues an RTE (return from exception handler) instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

www.DataSheet4U.com Rev. 5.0, 09/03, page 111 of 806

3.5.3 TLB Invalid Exception

A TLB invalid exception occurs when the virtual address is compared to a selected TLB entry address array and a match is found but the entry is not valid (the V bit is 0). TLB invalid exception handling includes both hardware and software operations.

Hardware Operations: In a TLB invalid exception, the SH7729R hardware executes a set of prescribed operations, as follows:

- 1. The VPN number of the virtual address causing the exception is written to the PTEH register.
- 2. The virtual address causing the exception is written to the TEA register.
- 3. The way number causing the exception is written to RC in MMUCR.
- 4. Either exception code H'040 for a load access, or H'060 for a store access, is written to the EXPEVT register.
- 5. The PC value indicating the address of the instruction in which the exception occurred is written to SPC. If the exception occurred in a delay slot, the PC value indicating the address of the delayed branch instruction is written to SPC.
- 6. The contents of SR at the time of the exception are written to SSR.
- 7. The mode (MD) bit in SR is set to 1 to place the SH7729R in privileged mode.
- 8. The block (BL) bit in SR is set to 1 to mask any further exception requests.
- 9. The register bank (RB) bit in SR is set to 1.
- 10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100, and the TLB protection violation exception handler starts.

Software (TLB Invalid Exception Handler) Operations: The software searches the page tables in external memory and assigns the required page table entry. Upon retrieving the required page table entry, software must execute the following operations:

- 1. Write the values of the physical page number (PPN) field and the values of the protection key (PR), page size (SZ), cacheable (C), dirty (D), share status (SH), and valid (V) bits of the page table entry recorded in the external memory to the PTEL register.
- 2. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
- 3. Issue an LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
- 4. Issue an RTE instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

3.5.4 Initial Page Write Exception

An initial page write exception occurs in a write access when the virtual address and the address array of the selected TLB entry are compared and a valid entry with the appropriate access rights is found to match, but the D (dirty) bit of the entry is 0 (the page has not been written to). Initial page write exception handling includes both hardware and software operations.

www.DataSheet4U.com

Hardware Operations: In an initial page write exception, the SH7729R hardware executes a set of prescribed operations, as follows:

- 1. The VPN field of the virtual address causing the exception is written to the PTEH register.
- 2. The virtual address causing the exception is written to the TEA register.
- 3. Exception code H'080 is written to the EXPEVT register.
- 4. The PC value indicating the address of the instruction in which the exception occurred is written to SPC. If the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written to SPC.
- 5. The contents of SR at the time of the exception are written to SSR.
- 6. The MD bit in SR is set to 1 to place the SH7729R in privileged mode.
- 7. The BL bit in SR is set to 1 to mask any further exception requests.
- 8. The register bank (RB) bit in SR is set to 1.
- 9. The way that caused the exception is set in the RC field in MMUCR.
- 10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100 to invoke the user-written initial page write exception handler.

Software (Initial Page Write Handler) Operations: The software must execute the following operations:

- 1. Retrieve the required page table entry from external memory.
- 2. Set the D bit of the page table entry in external memory to 1.
- 3. Write the value of the PPN field and the PR, SZ, C, D, SH, and V bits of the page table entry in the external memory to the PTEL register.
- 4. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
- 5. Issue an LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
- 6. Issue an RTE instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

3.5.6 MMU Exception in Repeat Loop

When an MMU exception or CPU address error occurs immediately before or within a repeat loop, the PC of the instruction that generated the exception cannot be saved in SPC correctly and the repeat loop cannot be restarted after returning from the exception handler. EXPEVT is set to H'070 in cases of TLB miss, TLB invalid, and CPU address error. EXPEVT is set to H'0D0 in case of TLB protection violation. Figure 3.14 shows where such cases occur.

In a repeat loop of 4 or more instructions, only the last 4 instructions are relevant (see figure 3.14 (4)).

3.6 Memory-Mapped TLB

In order for TLB operations to be managed by software, TLB contents can be read or written to in privileged mode using the MOV instruction. The TLB is assigned to the P4 area in the virtual address space. The TLB address array (VPN, V bit, and ASID) is assigned to H'F2000000–H'F2FFFFF, and the data array (PPN, PR, SZ, C, D, and SH bits) to H'F3000000–H'F3FFFFFF. The V bit in the address array can also be accessed from the data array. Only longword access is possible for both the address array and the data array.

3.6.1 Address Array

The address array is assigned to H'F2000000–H'F2FFFFF. To access an address array, the 32-bit address field (for read/write operations) and 32-bit data field (for write operations) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the VPN, V bit and ASID to be written to the address array (figure 3.15 (1)).

In the address field, specify VPN (16–12) as the index address for selecting the entry (bits 16–12), the W bits for selecting the way (bits 9–8), and H'F2 to indicate address array access (bits 31–24). The IX bit in MMUCR indicates whether the EX-OR of VPN (16–12) and ASID (4–0) in the PTEH register is used as the index address.

When writing, the write is performed to the entry selected with the index address and way.

When reading, the VPN, V bit, and ASID of the entry selected with the index address and way in the format of the data field in figure 3.12 without comparing addresses. 0 is written to data field bits 16–12.

To invalidate a specific entry, specify the entry and way, and write 0 to the corresponding V bit.

3.6.2 Data Array

The data array is assigned to H'F3000000–H'F3FFFFF. To access a data array, the 32-bit address field (for read/write operations), and 32-bit data field (for write operations) must be specified. The address section specifies information for selecting the entry to be accessed; the data section specifies the longword data to be written to the data array (figure 3.15 (2)). Longword data has the same bit configuration as PTEL.

In the address field, specify VPN (16–12) as the index address for selecting the entry (bits 16–12), the W bits for selecting the way (bits 9–8), and H'F3 to indicate data array access (bits 31–24). The IX bit in MMUCR indicates whether the EX-OR of VPN (16–12) and ASID (4–0) in the PTEH register is used as the index address.

Both reading and writing use longword data of the data array specified by the entry address and way number.

Figure 3.15 Specifying Address and Data for Memory-Mapped TLB Access

Invalidating Specific Entries: Specific TLB entries can be invalidated by writing 0 to the entry's V bit. R0 specifies the write data and R1 specifies the address.

```
; R0=H'1547 381C R1=H'F201 30
; MMUCR.IX=0=et4U.com
; VPN(31-17)=B'0001 0101 0100 011 VPN(11-10)=B'10 ASID=B'0001 1100
; corresponding entry association is made from the entry selected by
; the VPN(16-12)=B'1 0011 index, the V bit of the hit way is cleared to
; 0,achieving invalidation.
MOV.L R0,@R1
```

Reading the Data of a Specific Entry: This example reads the data section of a specific TLB entry. The data is read in the bit order indicated in the data field in figure 3.15 (2) is read. R0 specifies the address and the data section of a selected entry is read to R1.

```
; R1=H'F300 4300 VPN(16-12)=B'00100 Way 3
; MOV.L @R0,R1
```

3.7 Usage Note

Instructions that manipulate the MD or BL bit in register SR (the LDC Rm, SR instruction, LDC @Rm+, SR instruction, and RTE instruction) and the following instruction, or the LDTLB instruction, should be used with the TLB disabled or in a fixed physical address space (the P1 or P2 space).

Section 4 Exception Handling

4.1 Overview

4.1.1 wwwFeatureset4U.com

Exception handling is separate from normal program processing, and is performed by a routine separate from the normal program. In response to an exception handling request due to abnormal termination of the executing instruction, control is passed to a user-written exception handler. However, in response to an interrupt request, normal program execution continues until the end of the executing instruction. Here, all exceptions other than resets and interrupts will be called general exceptions. There are thus three types of exceptions: resets, general exceptions, and interrupts.

4.1.2 Register Configuration

Table 4.1 lists the registers used for exception handling. A register with an undefined initial value should be initialized by software.

| Register | Abbr. | R/W | Size | Initial Value | Address |
|---------------------------|---------|-----|----------|--|--|
| TRAPA exception register | TRA | R/W | Longword | Undefined | H'FFFFFD0 |
| Exception event register | EXPEVT | R/W | Longword | Power-on reset: H'000 Manual reset: H'020 ^{*1} | H'FFFFFFD4 |
| Interrupt event register | INTEVT | R/W | Longword | Undefined | H'FFFFFD8 |
| Interrupt event register2 | INTEVT2 | R | Longword | Undefined | H'0400000 (H'A400000) ^{*2} |

Table 4.1Register Configuration

Notes: 1. H'000 is set in a power-on reset, and H'020 in a manual reset.

2. When address translation by the MMU does not apply, the address in parentheses should be used.

4.2 Exception Handling Function

4.2.1 Exception Handling Flow

In exception handling, the contents of the program counter (PC) and status register (SR) are saved in the saved program counter (SPC) and saved status register (SSR), respectively, and execution of the exception handler is invoked from a vector address. The return from exception handler (RTE) instruction is issued by the exception handler routine on completion of the routine, restoring the

www.DataSheet4U.com

Rev. 5.0, 09/03, page 123 of 806

contents of PC and SR to return to the processor state at the point of interruption and the address where the exception occurred.

A basic exception handling sequence consists of the following operations:

- 1. The contents of PC and SR are saved in SPC and SSR, respectively.
- 2. The block (BL) bit in SR is set to 1, masking any subsequent exceptions.
- 3. The mode (MD) bit in SR is set to 1 to place the SH7729R in privileged mode.
- 4. The register bank (RB) bit in SR is set to 1.
- 5. An exception code identifying the exception event is written to bits 11–0 of the exception event (EXPEVT) or interrupt event (INTEVT or INTEVT2) register.
- 6. Instruction execution jumps to the designated exception vector address to invoke the handler routine.

4.2.2 Exception Vector Addresses

The reset vector address is fixed at H'A0000000. The other three events are assigned offsets from the vector base address by software. Translation look-aside buffer (TLB) miss exceptions have an offset from the vector base address of H'00000400. The vector address offset for general exception events other than TLB miss exceptions is H'00000100. The interrupt vector address offset is H'00000600. The vector base address is loaded into the vector base register (VBR) by software. The vector base address should reside in P1 or P2 fixed physical address space. Figure 4.1 shows the relationship between the vector base address, the vector offset, and the vector table.

Figure 4.1 Vector Table

In table 4.2, exceptions and their vector addresses are listed by exception type, instruction completion state, relative acceptance priority, relative order of occurrence within an instruction execution sequence and vector address for exceptions and their vector addresses.

| Exception Type | | Exception Event | Priority ^{*1} | Exception Order | Vector Address | Vector Offset |
|-----------------------|------------------------|--|------------------------|--------------------|-------------------|------------------|
| Reset | Aborted | Power-on reset | 1 | _ | H'A00000000 | _ |
| | | Manual reset | 1 | _ | H'A00000000 | _ |
| | DataSheet4U.c | UDI reset | 1 | _ | H'A00000000 | _ |
| General exception | Aborted and retried | CPU address error (instruction access) | 2 | 1 | _ | H'00000100 |
| events | | TLB miss (instruction access not in repeat loop) | 2 | 2 | _ | H'00000400 |
| | | TLB miss (instruction access in repeat loop)*4 | 2 | 2 | _ | H'00000100 |
| | | TLB invalid (instruction access) | 2 | 3 | _ | H'00000100 |
| | | TLB protection violation (instruction access) | 2 | 4 | _ | H'00000100 |

Table 4.2Exception Event Vectors

www.DataSheet4U.com

Rev. 5.0, 09/03, page 125 of 806

- Notes: 1. Priorities are indicated from high to low, 1 being the highest and 4 the lowest.
 - 2. The user defines the break point traps. 1 is a break point before instruction execution and 11 is a break point after instruction execution. For an operand break point, use 11.
 - 3. Use software to specify relative priorities of external hardware interrupts and peripheral module interrupts (see section 7, Interrupt Controller (INTC)).
 - 4. See section 4.5.2, General Exceptions, for details.

www.DataSheet4U.com

4.2.3 Acceptance of Exceptions

Processor resets and interrupts are asynchronous events unrelated to the instruction stream. All exception events are prioritized to establish an acceptance order whenever two or more exception events occur simultaneously.

All general exception events occur in a relative order in the execution sequence of an instruction (i.e. execution order), but are handled at priority level 2 in instruction-stream order (i.e. program order), where an exception detected in a preceding instruction is accepted prior to an exception detected in a subsequent instruction.

Three general exception events (reserved instruction code exception, unconditional trap, and slot illegal instruction exception) are detected in the decode stage (ID stage) of different instructions and are mutually exclusive events in the instruction pipeline. They have the same execution priority. Figure 4.2 shows the order of general exception acceptance.

| Pipeline Sequence | e: | | | | | | |
|---|----------------------------|------------------|------------|-----------|---------|---|--|
| Instruction n | IF ID | EX MA | WB |] | | | |

| IF = Instruction for ID = Instruction of EX = Instruction e MA = Memory acc WB = Write back | lecode execution | | | | | | |

Figure 4.2 Example of Acceptance Order of General Exceptions

All exceptions other than a reset are detected in the pipeline ID stage, and accepted at instruction boundaries. However, an exception is not accepted between a delayed branch instruction and the delay slot. A re-execution type exception detected in a delay slot is accepted before execution of the delayed branch instruction. A completion type exception detected in a delayed branch instruction. The delay slot here refers to the next instruction after a delayed unconditional branch instruction, or the next instruction when a delayed conditional branch instruction is true.

www.DataSheet4U.com Rev. 5.0, 09/03, page 127 of 806

4.2.4 Exception Codes

Table 4.3 lists the exception codes written to EXPEVT register (for reset or general exceptions) or the INTEVT and INTEVT2 registers (for general interrupt requests) to identify each specific exception event.

| Exception Type | Exception Event | Exception Code | | |
|----------------------------|---|----------------|--|--|
| Reset | Power-on reset | H'000 | | |
| | Manual reset | H'020 | | |
| | UDI reset | H'000 | | |
| General exception events | TLB miss/invalid (read) | H'040 | | |
| | TLB miss/invalid (write) | H'060 | | |
| | TLB miss/invalid/CPU Address error in repeat loop | H'070 | | |
| | Initial page write | H'080 | | |

| | IRL3–IRL0 = 1110 | H'3C0 | | |

4.2.5 Exception Request Masks

When the BL bit in SR is 0, exceptions and interrupts are accepted.

If a general exception event occurs when the BL bit in SR is 1, the CPU's internal registers are set to their post-reset state, other module registers retain their contents prior to the general exception, and a branch is made to the same address (H'A0000000) as for a reset.

If a general interrupt occurs when BL = 1, the request is masked (held pending) and not accepted until the BL bit is cleared to 0 by software. For reentrant exception handling, SPC and SSR must be saved and the BL bit in SR cleared to 0.

4.2.6 Returning from Exception Handling

The RTE instruction is used to return from exception handling. When RTE is executed, the SPC value is set in PC, and the SSR value in SR, and the return from exception handling is performed by branching to the SPC address.

If SPC and SSR have been saved in external memory, set the BL bit in SR to 1, then restore SPC and SSR, and issue an RTE instruction.

www.DataSheet4U.com Rev. 5.0, 09/03, page 129 of 806

4.3 **Register Descriptions**

There are four registers related to exception handling. These are peripheral module registers, and therefore reside in area P4. They can be accessed by specifying the address in privileged mode only.

- 1. The exception event register (EXPEVT) resides at address H'FFFFFD4, and contains a 12-bit exception code. The exception code set in EXPEVT is that for a reset or general exception event. The exception code is set automatically by hardware when an exception occurs. EXPEVT can also be modified by software.
- 2. The interrupt event register (INTEVT) resides at address H'FFFFFD8, and contains a 12-bit interrupt exception code or a code indicating the interrupt priority. Which is set when an interrupt occurs depends on the interrupt source (see tables 7.4 and 7.5). The exception code or interrupt priority code is set automatically by hardware when an exception occurs. INTEVT can also be modified by software.
- 3. Interrupt event register 2 (INTEVT2) resides at address H'04000000, and contains a 12-bit exception code. The exception code set in INTEVT2 is that for an interrupt request. The exception code is set automatically by hardware when an exception occurs.
- 4. The TRAPA exception register (TRA) resides at address H'FFFFFD0, and contains 8-bit immediate data (imm) for the TRAPA instruction. TRA is set automatically by hardware when a TRAPA instruction is executed. TRA can also be modified by software.

The bit configurations of the EXPEVT, INTEVT, INTEVT2, and TRA registers are shown in figure 4.3.

| EXPEVT register, IN | TEVT and IN | TEVT2 registers | TRA register | | | |
|---|---------------|-----------------|--------------|----|-----|----|
| 31 | 11 | 0 | 31 | 9 | | 20 |
| 0 | - 0 Exception | on code | 0 | _0 | imm | 00 |
| 0: Reserved bits, imm: 8-bit immediate | • | | | | | |

Figure 4.3 Bit Configurations of EXPEVT, INTEVT, INTEVT2, and TRA Registers

4.4 Exception Handling Operation

4.4.1 Reset

The reset sequence is used to power up or restart the SH7729R from the initialization state. The **RESETP** and **RESETM** signals are sampled every clock cycle, and in the case of a power-on reset, all processing being executed (excluding the RTC) is suspended, all unfinished events are canceled, and reset processing is executed immediately. In the case of a manual reset, however, reset processing is executed after completion of any memory access being executed. The reset sequence consists of the following operations:

- 1. The MD bit in SR is set to 1 to place the SH7729R in privileged mode.
- 2. The BL bit in SR is set to 1, masking any subsequent exceptions (except the NMI interrupt when the BLMSK bit is 1).
- 3. The RB bit in SR is set to 1.
- 4. An encoded value of H'000 in a power-on reset or H'020 in a manual reset is written to bits 11– 0 of the EXPEVT register to identify the exception event.
- 5. Instruction execution jumps to the user-written exception handler at address H'A0000000.

4.4.2 Interrupts

An interrupt handling request is accepted on completion of the current instruction. The interrupt acceptance sequence consists of the following operations:

- 1. The contents of PC and SR are saved to SPC and SSR, respectively.
- 2. The BL bit in SR is set to 1, masking any subsequent exceptions (except the NMI interrupt when the BLMSK bit is 1).
- 3. The MD bit in SR is set to 1 to place the SH7729R in privileged mode.
- 4. The RB bit in SR is set to 1.
- 5. An encoded value identifying the exception event is written to bits 11–0 of the INTEVT and INTEVT2 registers.
- 6. Instruction execution jumps to the vector location designated by the sum of the value of the contents of the vector base register (VBR) and H'00000600 to invoke the exception handler.

www.DataSheet4U.com Rev. 5.0, 09/03, page 131 of 806

4.4.3 General Exceptions

When the SH7729R encounters any exception condition other than a reset or interrupt request, it executes the following operations:

- 1. The contents of PC and SR are saved to SPC and SSR, respectively.
- 2. The BL bit in SR is set to 1, masking any subsequent exceptions (except the NMI interrupt when the BLMSK bit is 1).
- 3. The MD bit in SR is set to 1 to place the SH7729R in privileged mode.
- 4. The RB bit in SR is set to 1.
- 5. An encoded value identifying the exception event is written to bits 11–0 of the EXPEVT register.
- 6. Instruction execution jumps to the vector location designated by either the sum of the vector base address and offset H'00000400 in the vector table in a TLB miss trap, or by the sum of the vector base address and offset H'00000100 for exceptions other than TLB miss traps, to invoke the exception handler.

4.5 Individual Exception Operations

This section describes the conditions for specific exception handling, and this LSI operations.

4.5.1 Resets

- Power-On Reset
 - Conditions: RESETP low
 - Operations: EXPEVT set to H'000, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'0000000. In SR, the MD, RB and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip peripheral modules are initialized. See the register descriptions in the relevant sections for details. A power-on reset must always be performed when powering on. A low level is output from the RESETOUT pin, and a high level is output from the STATUS0 and STATUS1 pins.
- Manual Reset
 - Conditions: RESETM low
 - Operations: EXPEVT set to H'020, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'0000000. In SR, the MD, RB, and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip peripheral modules are initialized. See the register descriptions in the relevant sections for details. A low level is output from the RESETOUT pin, and a high level is output from the STATUS0 and STATUS1 pins.

- UDI Reset
 - Conditions: UDI reset command input (see section 23.4.3, UDI Reset)
 - Operations: EXPEVT set to H'000, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'0000000. In SR, the MD, RB and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip peripheral modules are initialized. See the register descriptions in the relevant sections for details.

Table 4.4Types of Reset

| | Conditions for Transition | Internal State | | | | |
|-------------------|---------------------------|----------------|---|--|--|--|
| Туре | to Reset State | CPU | On-Chip Peripheral Modules | | | |
| Power-on reset | RESETP = Low | Initialized | (See register configuration in relevant sections) | | | |
| Manual reset | RESETM = Low | Initialized | | | | |
| UDI reset | UDI reset command input | Initialized | | | | |

4.5.2 General Exceptions

- TLB miss exception
 - Conditions: Comparison of TLB addresses shows no address match.
 - Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31–10). The ASID of PTEH indicates the ASID at the time the exception occurred. If all ways are valid, 1 is added to the RC bit in MMUCR. If there is one or more invalid way, they are set by priority starting with way 0.

PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. If the exception occurred during a read, H'040 is set in EXPEVT; if the exception occurred during a write, H'060 is set in EXPEVT. The BL, MD and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0400.

To speed up TLB miss processing, the offset differs from other exceptions.

- TLB invalid exception
 - Conditions: Comparison of TLB addresses shows address match but the TLB entry valid bit (V) is 0.
 - Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31–10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bits in MMUCR.

PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. If the exception occurred during a read, H'040 is set in EXPEVT; if the exception occurred during a write, H'060 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- TLB exception/CPU address error in repeat loop
 - Conditions: TLB miss, TLB invalid or CPU address error in the last several instructions of repeat loop (see section 3.5.6, MMU Exception in Repeat Loop)
 - Operations: TEA, PTEH and RC bit in MMUCR are set in the way of the type of exception.

SR of the instruction that generated the exception is saved to SSR, but SPC is not the PC of the instruction that generated the exception. A repeat loop cannot be restarted after returning from the exception handler. In order to complete a repeat loop, ensure that a TLB exception or CPU address error does not occur in the last several instructions of the repeat loop (see section 3.5.6, MMU Exception in Repeat Loop). If a TLB exception or CPU address error occurs in the last several instructions of a repeat loop, H'070 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- Initial page write exception
 - Conditions: A hit occurred to the TLB for a store access, but the TLB entry data bit (D) is 0.

This occurs for initial writes to the page registered by the load.

— Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31–10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bit in MMUCR.

PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. H'080 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- TLB protection exception
 - Conditions: When a hit access violates the TLB protection information (PR bits) shown below:

| | PR | Privileged mode | User mode |
|---|----------------------|--------------------|--------------------|
| | 00 | Only read enabled | No access |
| V | / 01 /.DataSI | Read/write enabled | No access |
| | 10 | Only read enabled | Only read enabled |
| | 11 | Read/write enabled | Read/write enabled |

— Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31–10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bits in MMUCR.

PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. If the exception occurred during a read, H'0A0 is set in EXPEVT; if the exception occurred during a write, H'0C0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- TLB protection exception in repeat loop
 - Conditions: TLB protection exception in the last several instruction of a repeat loop (see section 3.5.6, MMU Exception in Repeat Loop)
 - Operations: TEA, PTEH, and RC bit in MMUCR are set in the way of the type of exception.

SR of the instruction that generated the exception is saved to SSR, but SPC is not the PC of the instruction that generated the exception. A repeat loop cannot be restarted after returning from the exception handler. In order to complete a repeat loop, ensure that a TLB exception or CPU address error does not occur in the last several instructions of the repeat loop (see section 3.5.6, MMU Exception in Repeat Loop). If a TLB protection exception occurs in an instruction immediately before or during a repeat loop, H'0D0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- CPU address error
 - Conditions:
 - a. Instruction fetch from odd address (4n + 1, 4n + 3)
 - b. Word data accessed from addresses other than word boundaries (4n + 1, 4n + 3)
 - c. Longword accessed from addresses other than longword boundaries $(4n+1,\,4n+2,\,\,4n+3)$
 - d. Virtual space accessed in user mode in the area H'80000000 to H'FFFFFFFF

www.DataSheet4U.com Rev. 5.0, 09/03, page 135 of 806

— Operations: The virtual address (32 bits) that caused the exception is set in TEA. PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. If the exception occurred during a read, H'0E0 is set in EXPEVT; if the exception occurred during a write, H'100 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100. See section 3.5.5, Processing Flow in Event of MMU Exception, for more information.

www.DataSheet4U.cor

- Unconditional trap
 - Conditions: TRAPA instruction executed
 - Operations: The exception is a processing-completion type, so PC of the instruction after the TRAPA instruction is saved to SPC. SR from the time when the TRAPA instruction was executing is saved to SSR. The 8-bit immediate value in the TRAPA instruction is quadrupled and set in TRA (9–0). H'160 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.
- Illegal general instruction exception
 - Conditions:
 - a. When undefined code not in a delay slot is decoded
 Delay branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S

Undefined instruction: H'Fxxx

- b. When a privileged instruction not in a delay slot is decoded in user mode Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions and therefore do not apply.
- c. When a DSP instruction not in a delay slot is decoded without DSP extension (SR.DSP=0)

DSP instructions: LDS Rm, DSR/A0/X0/X1/Y0/Y1, LDS.L @Rm+, DSR/A0/X0/X1/Y0/Y1, STS DSR/A0/X0/X1/Y0/Y1, Rn, STS.L DSR/A0/X0/X1/Y0/Y1, @-Rn, LDC Rm, RS/RE/MOD, LDC.L @Rm+, RS/RE/MOD, STC RS/RE/MOD, Rn, STC.L RS/RE/MOD, @-Rn, LDRS, LDRE, SETRC, MOVS, MOVX, MOVY, Pxxx

d. When an instruction that rewrites PC/SR/RS/RE in the last three instructions of repeat loop is decoded.

Instructions that rewrite PC: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT, BF, BT/S, BF/S, TRAPA, LDC Rm, SR, LDC.L @Rm+, SR
Instructions that rewrite SR: LDC Rm, SR, LDC.L @Rm+, SR, SETRC
Instructions that rewrite RS: LDC Rm, RS, LDC.L @Rm+, RS, LDRS
Instructions that rewrite RE: LDC Rm, RE, LDC.L @Rm+, RE, LDRE

www.DataSheet4U.com

- Operations: PC and SR of the instruction that generated the exception are saved to SPC and SSR, respectively. H'180 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100. When an undefined instruction other than H'Fxxx is decoded, operation cannot be guaranteed.
- Illegal slot instruction
 - Conditions: et4U.com
 - a. When undefined code in a delay slot is decoded
 Delay branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S
 - b. When an instruction that rewrites PC in a delay slot is decoded Instructions that rewrite PC: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT, BF, BT/S, BF/S, TRAPA, LDC Rm, SR, LDC.L @Rm+, SR
 - c. When a privileged instruction in a delay slot is decoded in user mode Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions and therefore do not apply.
 - d. When a DSP instruction in a delay slot is decoded without DSP extension (SR.DSP=0)

DSP instructions: LDS Rm, DSR/A0/X0/X1/Y0/Y1, LDS.L @Rm+, DSR/A0/X0/X1/Y0/Y1, STS DSR/A0/X0/X1/Y0/Y1, Rn, STS.L DSR/A0/X0/X1/Y0/Y1, @-Rn, LDC Rm, RS/RE/MOD, LDC.L @Rm+, RS/RE/MOD, STC RS/RE/MOD, Rn, STC.L RS/RE/MOD, @-Rn, LDRS, LDRE, SETRC, MOVS, MOVX, MOVY, Pxxx

- Operations: PC of the previous delay branch instruction is saved to SPC. SR of the instruction that generated the exception is saved to SSR. H'1A0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100. When an undefined instruction other than H'Fxxx is decoded, operation cannot be guaranteed.
- User break point trap
 - Conditions: When a break condition set in the user break controller is satisfied
 - Operations: When a post-execution break occurs, PC of the next instruction after the instruction that set the break point is set in SPC. If a pre-execution break occurs, PC of the instruction that set the break point is set in SPC. SR when the break occurs is set in SSR. H'1E0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100. See section 8, User Break Controller, for more information.
- DMA address error
 - Conditions:
 - a. Word data accessed from addresses other than word boundaries (4n + 1, 4n + 3)
 - b. Longword accessed from addresses other than longword boundaries (4n + 1, 4n + 2, 4n + 3)

www.DataSheet4U.com Rev. 5.0, 09/03, page 137 of 806

— Operations: PC of the instruction immediately after the instruction executed before the exception occurs is saved to SPC. SR when the exception occurs is saved to SSR. H'5C0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

4.5.3 Interrupts

- 1. NMI
 - Conditions: NMI pin edge detection
 - Operations: PC after the instruction that receives the interrupt are saved to SPC, respectively. PC after the instruction that receives the interrupt is saved to SPC, and SR at the point the interrupt is accepted is saved to SSR. H'01C0 is set to INTEVT and INTEVT2. The BL, MD, and RB bits of the SR are set to 1 and a branch occurs to PC = VBR + H'0600. This interrupt is not masked by the interrupt mask bits in SR and is accepted with top priority when the BL bit in SR is 0. When the BL bit is 1, the interrupt is masked. See section 7, Interrupt Controller (INTC), for more information.
- 2. IRL Interrupts

The value of the interrupt mask bits in SR is lower than the IRL3–IRL0 level and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.

- Operations: The PC value after the instruction at which the interrupt is accepted is saved to SPC. SR at the time the interrupt is accepted is saved to SSR. The code corresponding to the IRL3–IRL0 level is set in INTEVT and INTEVT2. The corresponding code is given as H'200 + [IRL3–IRL0] × H'20. See table 7.5, for the corresponding codes. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to VBR + H'0600. The received level is not set in the interrupt mask bits in SR. See section 7, Interrupt Controller (INTC), for more information.
- 3. IRQ Pin Interrupts
 - Conditions: The IRQ pin is asserted, the interrupt mask bits in SR are lower than the IRQ priority level, and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.
 - Operations: The PC value after the instruction at which the interrupt is accepted is saved to SPC. SR at the point the interrupt is accepted is saved to SSR. The code corresponding to the interrupt source is set in INTEVT and INTEVT2. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to VBR + H'0600. The received level is not set in the interrupt mask bits in SR. See section 7, Interrupt Controller (INTC), for more information.

- 4. PINT Pin Interrupts
 - Conditions: The PINT pin is asserted, the interrupt mask bits in SR are lower than the PINT priority level, and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.
 - Operations: The PC value after the instruction at which the interrupt is accepted is saved to SPC. SR at the point the interrupt is accepted is saved to SSR. The code corresponding to the interrupt source is set in INTEVT and INTEVT2. The BL, MD, and RB bits of SR are set to 1 and a branch occurs to VBR + H'0600. The received level is not set in the interrupt mask bits in SR. See section 7, Interrupt Controller (INTC), for more information.
- 5. On-Chip Peripheral Interrupts
 - Conditions: The interrupt mask bits in SR are lower than the on-chip module (TMU, RTC, SCI, IrDA, SCIF, A/D, DMAC, WDT, REF) interrupt level and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.
 - Operations: The PC value after the instruction at which the interrupt is accepted is saved to SPC. SR at the point the interrupt is accepted is saved to SSR. The code corresponding to the interrupt source is set in INTEVT and INTEVT2. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to VBR + H'0600. See section 7, Interrupt Controller (INTC), for more information.
- 6. UDI Interrupt
 - Conditions: An UDI interrupt command is input (see section 23.4.4, UDI Interrupt), SR.IMASK is lower than 15, and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.
 - Operations: The PC value after the instruction that accepts the interrupt is saved to SPC. SR at the point the interrupt is accepted is saved to SSR. H'5E0 is set to INTEVT and INTEVT2. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to VBR + H'0600. See section 7, Interrupt Controller (INTC), for more information.

4.6 Cautions

- Return from exception handling
 - Check the BL bit in SR with software. When SPC and SSR have been saved to external memory, set the BL bit in SR to 1 before restoring them.
 - Issue an RTE instruction, which sets SPC in PC and SSR in SR, and causes a branch to the SPC address, and return from exception handling.
- Operation when exception or interrupt occurs while SR.BL = 1
 - Interrupt: Acceptance is suppressed until the BL bit in SR is cleared to 0. If there is an interrupt request and the reception conditions are satisfied, the interrupt is accepted after the execution of the instruction that clears the BL bit in SR to 0. In sleep or standby mode, however, the interrupt will be accepted even when the BL bit in SR is 1.
 - Exception: No user break point trap will occur even when the break conditions are met. When one of the other exceptions occurs, a branch is made to the fixed address of the reset (H'A0000000). In this case, the values of the EXPEVT, SPC, and SSR registers are undefined. Differently from general reset processing, the RESETOUT pin is not asserted, and reset status is output from the STATUS0 and STATUS1 pins.
- SPC when exception occurs: The PC saved to SPC when an exception occurs is as shown below:
 - Re-executing-type exceptions: PC of the instruction that caused the exception is set in SPC and re-executed after return from exception handling. If the exception occurred in a delay slot, however, PC of the immediately prior delayed branch instruction is set in SPC. If the condition of the conditional delayed branch instruction is not satisfied, the delay slot PC is set in SPC.
 - Completed-type exceptions and interrupts: PC of the instruction after the one that caused the exception is set in SPC. If the exception was caused by a conditional delayed branch instruction, however, the branch destination PC is set in SPC. If the condition of the conditional delayed branch instruction is not satisfied, the delay slot PC is set in SPC.
- Initial register values after reset
 - Undefined registers

```
R0_BANK0/1-R7_BANK0/1, R8-R15, GBR, SPC, SSR, MACH, MACL, PR
```

- Initialized registers

VBR = H'00000000

SR.MD = 1, SR.BL = 1, SR.RB = 1, SR.I3-SR.I0 = H'F. Other SR bits are undefined. PC = H'A0000000

• Ensure that an exception is not generated at an RTE instruction delay slot, as operation is not guaranteed in this case.

www.DataSheet4U.com

Rev. 5.0, 09/03, page 140 of 806

• When the BL bit in the SR register is set to 1, ensure that a TLB-related exception or address error does not occur at an LDC instruction that updates the SR register and the following instruction. This will be identified as the occurrence of multiple exceptions, and may initiate reset processing.

Section 5 Cache

5.1 Overview

5.1.1 www.Featureset4U.com

The cache specifications are listed in table 5.1.

| Parameter | Specification |
|--------------------|---|
| Capacity | 16 kbytes |
| Structure | Instructions/data mixed, 4-way set associative |
| Locking | Way 2 and way 3 are lockable |
| Line size | 16 bytes |
| Number of entries | 256 entries/way |
| Write system | P0, P1, P3, U0: Write-back/write-through selectable |
| Replacement method | Least-recently-used (LRU) algorithm |

Table 5.1Cache Specifications

5.1.2 Cache Structure

The cache mixes data and instructions and uses a 4-way set associative system. It is composed of four ways (banks), each of which is divided into an address section and a data section. Each of the address and data sections is divided into 256 entries. The data section of the entry is called a line. Each line consists of 16 bytes (4 bytes \times 4). The data capacity per way is 4 kbytes (16 bytes \times 256 entries), with a total of 16 kbytes in the cache as a whole (4 ways). Figure 5.1 shows the cache structure.

www.DataSheet4U.com Rev. 5.0, 09/03, page 143 of 806

Figure 5.1 Cache Structure

Address Array: The V bit indicates whether the entry data is valid. When the V bit is 1, data is valid; when 0, data is not valid. The U bit indicates whether the entry has been written to in write-back mode. When the U bit is 1, the entry has been written to; when 0, it has not. The address tag holds the physical address used in the external memory access. It is composed of 22 bits (address bits 31–10) used for comparison during cache searches.

In the SH7729R, the top three of 32 physical address bits are used as shadow bits (see section 11, Bus State Controller (BSC)), and therefore in a normal replace operation the top three bits of the tag address are cleared to 0.

The V and U bits are initialized to 0 by a power-on reset, but are not initialized by a manual reset. The tag address is not initialized by either a power-on or manual reset.

Data Array: Holds a 16-byte instruction or data. Entries are registered in the cache in line units (16 bytes). The data array is not initialized by a power-on or manual reset.

LRU: With the 4-way set associative system, up to four instructions or data with the same entry address (address bits 11–4) can be registered in the cache. When an entry is registered, LRU shows which of the four ways it is recorded in. There are six LRU bits, controlled by hardware. A least-recently-used (LRU) algorithm is used to select the way.

In normal operation, four ways are used as cache and six LRU bits indicate the way to be replaced (table 5.2). If a bit pattern other than those listed in table 5.2 is set in the LRU bits by software, the cache will not function correctly. When modifying the LRU bits by software, set one of the patterns listed in table 5.2.

The LRU bits are initialized to 0 by a power-on reset, but are not initialized by a manual reset. www.DataSheet4U.com

Rev. 5.0, 09/03, page 144 of 806

| LRU (5–0) | Way to be Replaced |

5.1.3 Register Configuration

Table 5.3 shows details of the cache control registers.

Table 5.3Register Configuration

| Register | Abbr. | R/W | Initial Value | Address | Access Size |
|--------------------------|-------|-----|---------------|-----------------------------|-------------|
| Cache control register | CCR | R/W | H'00000000 | H'FFFFFFEC | 32 |
| Cache control register 2 | CCR2 | W | H'00000000 | H'040000B0 (H'A40000B0)* | 32 |

Note: * When address translation by the MMU does not apply, the address in parentheses should be used.

5.2 **Register Descriptions**

5.2.1 Cache Control Register (CCR)

The cache is enabled or disabled using the CE bit in the cache control register (CCR). CCR also has a CF bit (which invalidates all cache entries), and WT and CB bits (which select either write-through mode or write-back mode). Programs that change the contents of the CCR register should be placed in address space that is not cached. When updating the contents of the CCR register, bit 4 must always be cleared to 0. Figure 5.2 shows the configuration of the CCR register.

www.DataSheet4U.com Rev. 5.0, 09/03, page 145 of 806

| 31 | 6 5 4 | 3 | 2 | 1 | 0 |
|---------|--|-----------|---------|-------|----|
| | 0 0 | CF | СВ | WT | CE |
| Bits 5, | , 4: Always set to 0 when setting the register. | | | | |
| CF: | Cache flush bit. Writing 1 flushes all cache entries (clears the V cache entries to 0). Always reads 0. Write-back to external mer W. Dthe cache is flushed. | | | | |
| CB: | Cache write-back bit. Indicates the cache's operating mode for 1 = write-back mode, 0 = write-through mode. | area P | 1. | | |
| WT: | Write-through bit. Indicates the cache's operating mode for are 1 = write-through mode, 0 = write-back mode. | eas P0, I | U0, and | d P3. | |
| CE: | Cache enable bit. Indicates whether the cache function is used 1 = cache used, 0 = cache not used. | d. | | | |

Figure 5.2 CCR Register Configuration

5.2.2 Cache Control Register 2 (CCR2)

CCR2 register is used to enable or disable the cache locking mechanism in DSP mode (set by CPU status register bit 12) only. Executing a prefetch instruction (PREF) in DSP mode will bring the line of data pointed to by Rn into the cache, according to the setting of CCR2 [9:8] (W3LOAD, W3LOCK) and [1:0] (W2LOAD, W2LOCK).

When CCR2[9:8]=11, in DSP mode PREF @Rn will bring the data into way 3. When CCR2[9:8]=00, 01, or 10 in DSP mode, or any setting in non-DSP mode, PREF @Rn will place the data into the way pointed to by LRU.

When CCR2[1:0]=11, in DSP mode PREF @Rn will bring the data into way 2. When CCR2[1:0]=00, 01, or 10 in DSP mode, or any setting in non-DSP mode, PREF @Rn will place the data into the way pointed to by LRU.

CCR2 must be set before the cache is enabled (CCR.CE = 1).

When a PREF instruction is issued and there is a cache hit, the operation is treated as NOP.

Figure 5.3 shows the configuration of the CCR2 register.

CCR2 is a write-only register; if read, an undefined value will be returned.

Figure 5.3 CCR2 Register Configuration

Whenever CCR2 bit 8 (W3LOCK) or bit 0 (W2LOCK) is high the cache is locked. The locked data will not be overwritten unless the W3LOCK bit and W2LOCK bit are reset or the PREF condition in DSP mode matches. In cache locking mode, the LRU values in table 5.2 will be replaced by those in tables 5.4 to 5.6.

Table 5.4LRU and Way Replacement (when W2LOCK=1)

| LRU (5–0) | Way to be Replaced |
|--|--------------------|
| 000000, 000001, 000100, 010100, 100000, 100001, 110000, 110100 | 3 |

| 100000, 100001, 101001, 101011, 110000, 110100, 111000, 111001, 111011, 1111100, 111101, 111111 | 0 |

Table 5.6 LRU and Way Replacement (when W2LOCK=1 and W3LOCK=1)

5.3 Cache Operation

5.3.1 Searching the Cache

If the cache is enabled, whenever instructions or data in memory are accessed the cache will be searched to see if the desired instruction or data is in the cache. Figure 5.4 illustrates the method by which the cache is searched. The cache is a physical cache and holds physical addresses in its address section.

Entries are selected using bits 11–4 of the address (virtual) of the access to memory and the address tag of that entry is read. In parallel to reading of the address tag, the virtual address is translated to a physical address in the MMU. The physical address after translation and the physical address read from the address section are compared. The address comparison uses all four ways. When the comparison shows a match and the selected entry is valid (V = 1), a cache hit occurs. When the comparison does not show a match or the selected entry is not valid (V = 0), a cache miss occurs. Figure 5.4 shows a hit on way 1.

Figure 5.4 Cache Search Scheme (Normal Mode)

5.3.2 Read Access

Read Hit: In a read access, instructions and data are transferred from the cache to the CPU. The transfer unit is 32 bits. LRU is updated.

Read Miss: An external bus cycle starts and the entry is updated. The way replaced is the one least recently used. Entries are updated in 16-byte units. When the desired instruction or data that caused the miss is loaded from external memory to the cache, the instruction or data is transferred to the CPU in parallel with being loaded to the cache. When it is loaded in the cache, the U bit is cleared to 0 and the V bit is set to 1.

5.3.3 Write Access

Write Hit: In a write access in write-back mode, the data is written to the cache and the U bit of the entry written is set to 1. Writing occurs only to the cache; no external memory write cycle is issued. In write-through mode, the data is written to the cache and an external memory write cycle is issued.

Write Miss: In write-back mode, an external write cycle starts when a write miss occurs, and the entry is updated. The way to be replaced is the one least recently used. When the U bit of the entry to be replaced is 1, the cache fill cycle starts after the entry is transferred to the write-back buffer. The write-back unit is 16 bytes. Data is written to the cache and the U bit is set to 1. After the cache completes its fill cycle, the write-back buffer writes the entry back to the memory. In write-through mode, no write to cache occurs in a write miss; the write is only to the external memory.

5.3.4 Write-Back Buffer

When the U bit of the entry to be replaced in the write-back mode is 1, it must be written back to the external memory. To increase performance, the entry to be replaced is first transferred to the write-back buffer and fetching of new entries to the cache takes priority over writing back to the external memory. During the write-back cycles, the cache can be accessed. The write-back buffer can hold one line of cache data (16 bytes) and its physical address. Figure 5.5 shows the configuration of the write-back buffer.

| PA (31–4) | Longword 0 | Longword 1 | Longword 2 | Longword 3 |
|--------------------------|------------|--|------------|------------|
| PA (31–4): Longword 0 | , | address writh of cache data memory | | - |

Figure 5.5 Write-Back Buffer Configuration

5.3.5 Coherency of Cache and External Memory

Use software to ensure coherency between the cache and the external memory. When memory shared by this LSI and another device is accessed, the latest data may be in a write-back mode cache, so invalidate the entry that includes the latest data in the cache, generate a write-back, and update the data in memory before using it. When the caching area is updated by a device other than the SH7729R, invalidate the entry that includes the updated data in the cache.

5.4 Memory-Mapped Cache

To allow software management of the cache, cache contents can be read and written by means of MOV instructions in the privileged mode. The cache is mapped onto the P4 area in virtual address space. The address array is mapped onto addresses H'F0000000 to H'F0FFFFFF, and the data array onto addresses H'F1000000 to H'F1FFFFFF. Only longword can be used as the access size for the address array and data array, and instruction fetches cannot be performed.

5.4.1 Address Array

The address array is mapped to H'F0000000 to H'F0FFFFFF. The 32-bit address field (for read/write accessed) and 32-bit data field (for write access) must be specified to access an element of the address array. The address field specifies information that selects the entry to be accessed; the data field specifies the tag address, V bit, U bit, and LRU bits to be written to the address array (figure 5.6 (1)).

In the address field, specify the entry's address in bits 11-4 to select the entry, W in bits 13-12 to select the way, the A bit (bit 3) to specify an associative operation, and H'F0 in bits 31-24 to indicate access to the address array. Settings for the W bits (13-12) are as follows: 00 is way 0, 01 is way 1, 10 is way 2, and 11 is way 3.

In the data field, specify the tag address in bits 31-10, LRU in bits 9-4, U bit in bit 1, and V bit in bit 0. The upper 3 bits (bit 31-29) of the tag address must always be 0.

The following three operations on the address array are possible.

(1) Address Array Read

Reads the tag address, LRU, U bit, and V bit from the entry that corresponds to the entry address and w`ay that were specified in the address field. No associative operation will be performed, regardless of the value of the associative bit (the A bit).

(2) Address Array Write (without Associative Operation)

Writes the tag address, LRU, U bit, and V bit specified in the data field to the entry that corresponds to the entry address and way that were specified in the address field. The associative bit (A bit) of the address field must be set to 0. An attempt to write to a cache line for which both the U bit and V bit are set results in a write-back for that cache line. The tag address here the bit with the U bit are set results in a write-back for that cache line.

Rev. 5.0, 09/03, page 151 of 806

and V bit specified in the data field are then written. Note that, when a 0 is written to the V bit, a 0 should always be written to the U bit of the same entry, too.

(3) Address Array Write (with Associative Operation)

The associative bit (A bit) in the address field indicates whether the addresses are compared during writing. With the A bit set to 1, all 4 ways for the entry specified in the address field will be compared to the tag address specified in the data field for a match. The values of the U bit and V bit specified in the data field will be written to the way that has a hit. However, the tag address and the LRU will not be changed. If no way receives a hit, writing does not take place and the result is no operation.

This operation is used to invalidate the address specification for a cache. Write back will take place when the U bit of the entry that received a hit is 1. Note that, when a 0 is written to the V bit, a 0 should always be written to the U bit of the same entry, too.

5.4.2 Data Array

The address array is mapped to H'F1000000 to H'F1FFFFF. To access an element of the data array, the 32-bit address field (for read/write access) and 32-bit data field (for write access) must be specified. The address field specifies the information that selects the entry to be accessed; the data field specifies the longword data to be written to the data array.

In the address field, specify the entry's address in bits 11-4, L in bits 3-2 to indicate the longword's position within a line (which consists of 16 bytes), W in bits 13-12 to select the way, and H'F1 in bits 31-24 to indicate access to the data array. The L bits (3-2) specification is in the following form: 00 is longword 0, 01 is longword 1, 10 is longword 2, and 11 is longword 3. Settings for the W bits (13-12) are as follows: 00 is way 0, 01 is way 1, 10 is way 2, and 11 is way 3. Since access is not allowed crossing longword boundaries, always set 00 in bits 1-0 of the address field.

The following two operations on the data array are possible. Note that these operations will not change the information in the address array.

(1) Data Array Read

Reads the data at the position selected by the L bits (3-2) of the address field from the entry that corresponds to the entry address and way that were specified in the address field.

(2) Data Array Write

Writes the longword data set in the data field into the entry that corresponds to the entry address and way that were specified in the address field. The longword data will be written to the entry at the position selected by the L bits (3-2) of the address field.

Figure 5.6 Specifying Address and Data for Memory-Mapped Cache Access

5.5 Usage Examples

5.5.1 Invalidating a Specific Entry

A specific cache entry can be invalidated by accessing the allocated memory cache and writing a 0 to the entry's U and V bits. The A bit is cleared to 0, and an address is specified for the entry address and the way. If the U bit of the way of the entry in question was set to 1, the entry is written back and the V and U bits specified by the write data are written to.

In the following example, the write data is specified in R0 and the address is specified in R1.

```
; R0 = H'0000 0000 LRU = H'000, U = 0, V = 0
; R1 = H'F000 1080, Way = 1, Entry = H'08, A = 0
;
MOV.L R0, @R1
```

To invalidate all entries and ways, write 0 to the following addresses.

Addresses F000 0000 F000 0010 F000 0020 : F000 3FF0

This involves a total of 1,024 writes.

The above operation should be performed using a non-cacheable area.

www.DataSheet4U.com

5.5.2 Invalidating a Specific Address

A specific address can be invalidated by writing 0 to the entry's V bit. When the A bit is 1, the address tag specified by the write data is compared to the address tag within the cache selected by the entry address, and data is written when a match is found. If no match is found, there is no operation. R0 specifies the write data and R1 specifies the address. When the V bit of an entry in the address array is set to 0, the entry is written back if the entry's U bit is 1.

```
; R0=H'01100010; Tag address=B'0000 0001 0001 0000 0000 00, U=0, V=0
; R1=H'F0000088; address array access, entry=H'08, A=1
;
MOV.L R0,@R1
```

In the following example, an address (32-bit) to be purged is specified in R0.

The above operation should be performed using a non-cacheable area.

5.5.3 Reading the Data of a Specific Entry

This example reads the data section of a specific cache entry. The longword indicated in the data field of the data array in figure 5.6 is read into the register. R0 specifies the address and R1 is read.

```
; R1=H'F100 004C; data array access, entry=H'04, Way = 0,
; longword address = 3
;
MOV.L @R0,R1 ; Longword 3 is read.
```

Section 6 X/Y Memory

6.1 Overview

The SH7729R has on-chip X-RAM and Y-RAM. It can be used by the CPU, DSP and DMAC to store instructions of data.

6.1.1 Features

The X/Y memory features are listed in table 6.1.

| Parameter | Features |
|------------|--|
| Addressing | User selectable mapping mechanism |
| method | Fixed mapping for mission-critical realtime applications (P2/Uxy area) |
| | Automatic mapping through TLB for easy to use (P0/P3/U0 area) |
| Ports | Three independent read/write ports |
| | 8-/16-/32-bit access from the CPU |
| | Maximum of two simultaneous 16-bit accesses, or 16/32-bit accesses, from the DSP |
| | 8-/16-/32-bit access from the DMAC |
| Size | 8-kbyte RAM each for X and Y memory |

Table 6.1 X/Y Memory Specifications

6.2 X/Y Memory Access from CPU

The X/Y memory can be located in either a mappable area or fixed-mapped area, depending on the mode bit (MD) and DSP bit (DSP) setting in the status register (SR). Figure 6.1 shows X/Y memory logical mapping.

1. Privileged Modeet4U.com

MD = 1, DSP = 0: Any physical address in space P0 or P3 can map to X/Y memory through TLB translation. Addresses ranging from H'A500 0000 to H'A5FF FFFF in the P2 space can also fixed-map to X/Y memory. Since the DSP extension is disabled, the DSP instruction set and registers are not available to the programmer.

2. User Mode

MD = 0, DSP = 0: Any physical address in the U0 space can access X/Y memory through TLB translation. Any access to addresses beyond the U0 space will cause an address error. Since the DSP extension is disabled, the DSP instruction set and registers are not available to the programmer.

3. Privileged-DSP Mode

MD = 1, DSP = 1: Any physical address in space P0 or P3 can map to X/Y memory through TLB translation. Addresses ranging from H'A500 0000 to H'A5FF FFFF in the P2 space can also fixed-map to X/Y memory. Since the DSP extension is enabled, the DSP instruction set and registers are available to the programmer.

4. User-DSP Mode

MD = 0, DSP = 1: Any physical address in space U0 can map to X/Y memory through TLB translation. Addresses ranging from H'A500 0000 to H'A5FF FFFF in the Uxy spaces can also fixed-map to X/Y memory. Any access outside U0 and Uxy space will cause an address error. Since the DSP extension is enabled, the DSP instruction set and registers are available to the programmer.

For the mappable area, the C (cacheable) bit in the TLB entry must be cleared to 0 to guarantee a two-cycle access.

Mapping through TLB translation provides a flexible X/Y memory addressing scheme but takes two cycles even when the C bit in the TLB entry is cleared to 0. Fixed mapping provides a one-cycle access for read and two-cycle access for write, which is the appropriate method for mission-critical realtime operations.

The X/Y memory resides in the second 16 Mbytes of physical address space area 1, from H'A500 0000 to H'A5FF FFFF. This 16-Mbyte address space is shadowed and maps to the same 128-kbyte X/Y ROM/RAM. Figures 6.1 and 6.2 show X/Y memory physical mapping.

Figure 6.1 X/Y Memory Logical Address Mapping

Figure 6.2 X/Y Memory Physical Address Mapping

6.3 X/Y Memory Access from DSP

The X/Y memory can be accessed by the DSP through the X bus and Y bus. Accesses via the X bus/Y bus are always 16-bit, while accesses via the L bus are either 16-bit or 32-bit. Accesses via the X bus and Y bus cannot be specified simultaneously.

6.4 X/Y Memory Access from DMAC

The X/Y memory also exists on the I bus and can be accessed by the DMAC. DMAC access uses an 8-/16-/32-bit unit. If the I bus accesses X/Y memory simultaneously with an access from the X bus/Y bus or L bus, the I bus master has a higher priority.

When accessing X/Y memory from the DMAC, use physical addresses in the range H'05000000 to H'05FFFFFF.

Section 7 Interrupt Controller (INTC)

7.1 Overview

The interrupt controller (INTC) ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The INTC registers set the order of priority of each interrupt, allowing the user to process interrupt requests according to the user-set priority.

7.1.1 Features

The INTC has the following features:

- 16 levels of interrupt priority can be set: By setting the five interrupt-priority registers, the priorities of on-chip peripheral module, IRQ, and PINT interrupts can be selected from 16 levels for individual request sources.
- NMI noise canceler function: An NMI input-level bit indicates the NMI pin state. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as a noise canceler.
- External devices can be notified that an interrupt has been received (IRQOUT): When the SH7729R has released the bus, the external bus master can be notified that an external interrupt, an on-chip peripheral module interrupt, or a memory refresh request has occurred, enabling the bus to be requested.

7.1.2 Block Diagram

Figure 7.1 shows a block diagram of the INTC.

Rev. 5.0, 09/03, page 162 of 806

7.1.3 Pin Configuration

Table 7.1 shows the INTC pin configuration.

Table 7.1INTC Pins

| Namewww.DataSheet4U.com | Abbreviation | I/O | Description |
|---------------------------------|---------------------------------------|-----|---|
| Nonmaskable interrupt input pin | NMI | I | Input of interrupt request signal, not maskable by the interrupt mask bits in SR |
| Interrupt input pins | IRQ5-IRQ0 IRL3-IRL0 IRLS3-IRLS0 | I | Input of interrupt request signals, maskable by the interrupt mask bits in SR |
| Port interrupt input pins | PINT0-PINT15 | I | Input of port interrupt request signals, maskable by the interrupt mask bits in SR |
| Interrupt request output pin | IRQOUT | 0 | Output of signal that notifies external devices that an interrupt source or memory refresh has occurred |

7.1.4 Register Configuration

The INTC has the 12 registers listed in table 7.2.

Table 7.2INTC Registers

| Name www.DataSheet4U.com | Abbr. | R/W | Initial Value ^{*1} | Address | Access Size |
|--------------------------------|--------|-----|-----------------------------|--|----------------|
| Interrupt control register 0 | ICR0 | R/W | *2 | H'FFFFFEE0 | 16 |
| Interrupt control register 1 | ICR1 | R/W | H'0000 | H'04000010 (H'A4000010) ^{*3} | 16 |
| Interrupt control register 2 | ICR2 | R/W | H'0000 | H'04000012 (H'A4000012) ^{*3} | 16 |
| PINT interrupt enable register | PINTER | R/W | H'0000 | H'04000014 (H'A4000014) ^{*3} | 16 |
| Interrupt priority register A | IPRA | R/W | H'0000 | H'FFFFFEE2 | 16 |
| Interrupt priority register B | IPRB | R/W | H'0000 | H'FFFFFEE4 | 16 |
| Interrupt priority register C | IPRC | R/W | H'0000 | H'04000016 (H'A4000016) ^{*3} | 16 |
| Interrupt priority register D | IPRD | R/W | H'0000 | H'04000018 (H'A4000018) ^{*3} | 16 |
| Interrupt priority register E | IPRE | R/W | H'0000 | H'0400001A (H'A400001A) ^{*3} | 16 |
| Interrupt request register 0 | IRR0 | R/W | H'00 | H'04000004 (H'A4000004) ^{*3} | 8 |
| Interrupt request register 1 | IRR1 | R | H'00 | H'04000006 (H'A4000006) ^{*3} | 8 |
| Interrupt request register 2 | IRR2 | R | H'00 | H'0400008 (H'A400008) ^{*3} | 8 |

Notes: 1. Initialized by a power-on or manual reset.

2. H'8000 when the NMI pin is high, H'0000 when the NMI pin is low.

3. When address translation by the MMU does not apply, the address in parentheses should be used.

7.2 Interrupt Sources

There are five types of interrupt sources: NMI, IRQ, IRL,PINT, and on-chip peripheral modules. Each interrupt has a priority level (0–16), with 0 the lowest and 16 the highest. Priority level 0 masks an interrupt.

www.DataSheet4U.com

7.2.1 NMI Interrupt

The NMI interrupt has the highest priority level of 16. When the BLMSK bit in the interrupt control register (ICR1) is 1 or the BL bit in the status register (SR) is 0, NMI interrupts are accepted when the MAI bit in the ICR1 register is 0. NMI interrupts are edge-detected. In sleep or standby mode, the interrupt is accepted regardless of the BL setting. The NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is used to select either rising or falling edge detection. When the NMIE bit in the ICR0 register is changed, an NMI interrupt is not detected for 20 cycles after changing ICR0. NMIE to avoid a false detection of NMI. NMI interrupt exception handling does not affect the interrupt mask level bits (I3–I0) in the status register (SR).

When the BL bit is 1 and the BLMSK bit in the ICR1 register is set to 1 and only NMI interrupts are accepted, the SPC register and SSR register are updated by the NMI interrupt handler, making it impossible to return to the original processing from exception handling initiated prior to the NMI interrupt. Use should therefore be restricted to cases where return is not necessary.

It is possible to wake the chip up from the standby state with an NMI interrupt (except when the MAI bit in the ICR1 register is set to 1).

7.2.2 IRQ Interrupts

IRQ interrupts are input by level or edge from pins IRQ0–IRQ5. The priority level can be set by interrupt priority registers C–D (IPRC–IPRD) in a range from 0 to 15.

When using edge-sensing for IRQ interrupts, clear the interrupt source by having software read 1 from the corresponding bit in IRR0, then write 0 to the bit.

When the ICR1 register is rewritten, IRQ interrupts may be mistakenly detected, depending on the pin states. To prevent this, rewrite the register while interrupts are masked, then release the mask after clearing the illegal interrupt by writing 0 to interrupt request register 0 (IRR0).

Edge input interrupt detection requires input of a pulse width of more than two cycles on a P clock basis.

The interrupt mask bits (I3–I0) in the status register (SR) are not affected by IRQ interrupt handling.

www.DataSheet4U.com Rev. 5.0, 09/03, page 165 of 806

Interrupts IRQ4–IRQ0 can wake the chip up from the standby state when the relevant interrupt level is higher than the setting of I3–I0 in the SR register (but only when the RTC 32-kHz oscillator is used).

If the IRQ edge is input immediately before the CPU enters the standby mode (during the period between when the CPU executes a SLEEP instruction and when STATUS0 becomes high level), the interrupt may not be detected. However, the interrupt will be accepted correctly if the IRQ edge is re-input after the CPU has entered the standby mode (when STATUS0 is high level). In addition, the interrupt may not be detected if the IRQ edge is input during frequency change processing (WDT count).

7.2.3 IRL Interrupts

IRL interrupts are input by level at pins IRL3–IRL0 and IRLS3–IRLS0. IRLS3–IRLS0 are enabled when the IRQLVL bit and IRLSEN bit in interrupt control register 1 (ICR1) are both 1. The priority level is the higher level indicated by pins IRL3–IRL0 and IRLS3–IRLS0. An IRL3–IRL0/IRLS3–IRLS0 value of 0 (0000) indicates the highest-level interrupt request (interrupt priority level 15). A value of 15 (1111) indicates no interrupt request (interrupt priority level 0). Figure 7.2 shows an example of IRL interrupt connection. Table 7.3 shows IRL/IRLS pins and interrupt levels.

Figure 7.2 Example of IRL Interrupt Connection

| IRL3/ | IRL2/ | IRL1/ | IRLO/ | | |
|-------|-----------|--------------|--------------|--------------------------|----------------------------|
| IRLS3 | IRLS2 | IRLS1 | IRLS0 | Interrupt Priority Level | Interrupt Request |
| 0 | 0 | 0 | 0 | 15 | Level 15 interrupt request |
| 0 | 0 | 0 | 1 | 14 | Level 14 interrupt request |
| 0 . | wwoDataSh | eet4U.com | 0 | 13 | Level 13 interrupt request |
| 0 | 0 | 1 | 1 | 12 | Level 12 interrupt request |
| 0 | 1 | 0 | 0 | 11 | Level 11 interrupt request |
| 0 | 1 | 0 | 1 | 10 | Level 10 interrupt request |
| 0 | 1 | 1 | 0 | 9 | Level 9 interrupt request |
| 0 | 1 | 1 | 1 | 8 | Level 8 interrupt request |
| 1 | 0 | 0 | 0 | 7 | Level 7 interrupt request |
| 1 | 0 | 0 | 1 | 6 | Level 6 interrupt request |
| 1 | 0 | 1 | 0 | 5 | Level 5 interrupt request |
| 1 | 0 | 1 | 1 | 4 | Level 4 interrupt request |
| 1 | 1 | 0 | 0 | 3 | Level 3 interrupt request |
| 1 | 1 | 0 | 1 | 2 | Level 2 interrupt request |
| 1 | 1 | 1 | 0 | 1 | Level 1 interrupt request |
| 1 | 1 | 1 | 1 | 0 | No interrupt request |

 Table 7.3
 IRL3–IRL0/IRLS3–IRLS0
 Pins and Interrupt Levels

A noise-cancellation feature is built in, and the IRL interrupt is not detected unless the levels sampled at every peripheral module clock cycle remain unchanged for two consecutive cycles, so that no transient level on the IRL/IRLS pin change is detected. In standby mode, as the peripheral clock is stopped, noise cancellation is performed using the 32-kHz clock for the RTC instead. Therefore when the RTC is not used, interruption by means of IRL interrupts cannot be performed in standby mode.

The priority level of the IRL interrupt must not be lowered until the interrupt is accepted and interrupt handling starts. Correct operation cannot be guaranteed if the level is not maintained. However, the priority level can be changed to a higher one.

The interrupt mask bits (I3–I0) in the status register (SR) are not affected by $\overline{IRL}/\overline{IRLS}$ interrupt handling.

If the interrupt level of an IRL interrupt is higher than the setting in bits I3-I0 in the SR register, it can be used to recover from the standby state (but only when using the RTC 32-kHz oscillator).

www.DataSheet4U.com Rev. 5.0, 09/03, page 167 of 806

7.2.4 **PINT Interrupts**

PINT interrupts are input by level from pins PINT0–PINT15. The priority level can be set by interrupt priority register D (IPRD) in a range from 0 to 15, in groups of PINT0–PINT7 and PINT8–PINT15.

The PINT interrupt level should be held until the interrupt is accepted and interrupt handling is started. Correct operation cannot be guaranteed if the level is not maintained.

The interrupt mask bits (I3–I0) in the status register (SR) are not affected by PINT interrupt handling.

PINT interrupts can wake the chip up from the standby state when the relevant interrupt level is higher than the setting of I3–I0 in the SR register (but only when the RTC 32-kHz oscillator is used).

7.2.5 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following ten modules:

- Timer unit (TMU)
- Realtime clock (RTC)
- Serial communication interfaces (SCI, IrDA, SCIF)
- Bus state controller (BSC)
- Watchdog timer (WDT)
- Direct memory access controller (DMAC)
- Analog-to-digital converter (ADC)
- User-debugging interface (UDI)

Not every interrupt source is assigned a different interrupt vector. Sources are reflected in the interrupt event registers (INTEVT and INTEVT2). It is easy to identify sources by using the value of the INTEVT or INTEVT2 register as a branch offset.

A priority level (from 0 to 15) can be set for each module except UDI by writing to interrupt priority registers A, B, and E (IPRA, IPRB, and IPRE). The priority level of the UDI interrupt is 15 (fixed).

The interrupt mask bits (I3–I0) in the status register are not affected by on-chip peripheral module interrupt handling.

TMU and RTC interrupts can wake the chip up from the standby state when the relevant interrupt level is higher than the setting of I3–I0 in the SR register (but only when the RTC 32-kHz oscillator is used).

www.DataSheet4U.com

Rev. 5.0, 09/03, page 168 of 806

7.2.6 Interrupt Exception Handling and Priority

Tables 7.4 and 7.5 list the codes for the interrupt event registers (INTEVT and INTEVT2), and the order of interrupt priority. Each interrupt source is assigned a unique code. The start address of the interrupt service routine is common to each interrupt source. This is why, for instance, the value of INTEVT or INTEVT2 is used as offset at the start of the interrupt service routine and branched to in order to identify the interrupt source.

The priority of the on-chip peripheral module, IRQ, and PINT interrupts is set within priority levels 0–15 as required by using interrupt priority registers A–E (IPRA–IPRE). The priority of the on-chip peripheral module, IRQ, and PINT interrupts is set to 0 by a reset.

When the priorities of multiple interrupt sources are set to the same level and such interrupts are generated simultaneously, they are handled according to the default order shown in tables 7.4 and 7.5.

Table 7.6 Interrupt Levels and INTEVT Codes

7.3 INTC Registers

7.3.1 Interrupt Priority Registers A to E (IPRA–IPRE)

Interrupt priority registers A to E (IPRA to IPRE) are 16-bit readable/writable registers in which priority levels from 0 to 15 are set for on-chip peripheral module, IRQ, and PINT interrupts. These registers are initialized to H'0000 by a power-on reset or manual reset, but are not initialized in standby mode.

Table 7.7 lists the relationship between the interrupt sources and the IPRA—IPRE bits.

| Register | Bits 15 to 12 | Bits 11 to 8 | Bits 7 to 4 | Bits 3 to 0 |
|----------|----------------|-----------------|-------------|-------------|
| IPRA | TMU0 | TMU1 | TMU2 | RTC |
| IPRB | WDT | REF | SCI0 | Reserved* |
| IPRC | IRQ3 | IRQ2 | IRQ1 | IRQ0 |
| IPRD | PINT0 to PINT7 | PINT8 to PINT15 | IRQ5 | IRQ4 |
| IPRE | DMAC | IrDA | SCIF | ADC |

Table 7.7 Interrupt Request Sources and IPRA–IPRE

Note: * Always read as 0. Only 0 should be written.

As shown in table 7.7, on-chip peripheral module, IRQ, or PINT interrupts are assigned to four 4bit groups in each register. These 4-bit groups (bits 15 to 12, bits 11 to 8, bits 7 to 4, and bits 3 to 0) are set with values from H'0 (0000) to H'F (1111). Setting H'0 means priority level 0 (masking is requested); H'F is priority level 15 (the highest level). A reset initializes IPRA–IPRE to H'0000.

7.3.2 Interrupt Control Register 0 (ICR0)

ICR0 is a register that sets the input signal detection mode of external interrupt input pin NMI, and indicates the input signal level at the NMI pin. This register is initialized to H'0000 or H'8000 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Dat Bit he | eet4 15 om | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------------------|-------------------|----|----|----|----|----|---|------|
| | NMIL | _ | _ | | _ | _ | | NMIE |
| Initial value: | 0/1* | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | _ | _ | _ | | _ | _ | | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |
| | | | | | | | | |

Note: * 1 when NMI input is high, 0 when NMI input is low.

Bit 15—NMI Input Level (NMIL): Sets the level of the signal input at the NMI pin. This bit can be read to determine the NMI pin level. This bit cannot be modified.

| Bit 15: NMIL | Description |
|--------------|-------------------------|
| 0 | NMI input level is low |
| 1 | NMI input level is high |

Bit 8—NMI Edge Select (NMIE): Selects whether the falling or rising edge of the interrupt request signal at the NMI pin is detected.

| Bit 8: NMIE | Description |
|-------------|--|
| 0 | Interrupt request is detected on falling edge of NMI input |
| 1 | Interrupt request is detected on rising edge of NMI input |

Bits 14 to 9 and 7 to 0—Reserved: These bits are always read as 0. The write value should always be 0.

7.3.3 Interrupt Control Register 1 (ICR1)

ICR1 is a 16-bit register that specifies the detection mode for external interrupt input pins IRQ0 to IRQ5 individually: rising edge, falling edge, or low level. This register is initialized to H'4000 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Data Bit ee | et4U. 15 m | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|------------------------|-------------------|--------|--------|--------|--------|--------|--------|--------|
| | MAI | IRQLVL | BLMSK | IRLSEN | IRQ51S | IRQ50S | IRQ41S | IRQ40S |
| Initial value: | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | RW | R/W | R/W | R/W | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | IRQ31S | IRQ30S | IRQ21S | IRQ20S | IRQ11S | IRQ10S | IRQ01S | IRQ00S |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bit 15—Mask All Interrupts (MAI): When set to 1, all interrupt requests are masked while a low level is being input to the NMI pin. Masks NMI interrupts in standby mode.

| Bit 15: MAI | Description | |
|-------------|---|-----------------|
| 0 | All interrupt requests are not masked when NMI pin is low level | (Initial value) |
| 1 | All interrupt requests are masked when NMI pin is low level | |

Bit 14—Interrupt Request Level Detect (IRQLVL): Selects whether the IRQ3–IRQ0 pins are used as four independent interrupt pins or as 15-level interrupt pins encoded as IRL3–IRL0.

Bit 14: IRQLVL Description

| 0 | Used as four independent interrupt request pins IRQ3-IRQ0 | |
|---|---|-----------------|
| 1 | Used as 15-level interrupt pins encoded as IRL3-IRL0 | (Initial value) |

Bit 13—BL Bit Mask (BLMSK): Specifies whether NMI interrupts are masked when the BL bit in the SR register is 1.

Bit 13: BLMSK Description

| 0 | NMI interrupts are masked when BL bit is 1 | (Initial value) |
|---|--|-----------------|
| 1 | NMI interrupts are accepted regardless of BL bit setting | |

Bit 12—IRLS Enable (IRLSEN): Enables pins IRLS3–IRLS0. This bit is valid only when the IRQLVL bit is 1.

Bit 12: IRLSEN Description

| 0 | Pins IRLS3–IRLS0 disabled | (Initial value) |
|---|---------------------------|-----------------|
| 1 | Pins IRLS3-IRLS0 enabled | |

Bits 11 and 10—IRQ5 Sense Select (IRQ51S, IRQ50S): Select whether the interrupt signal to the IRQ5 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 11: IRQ51S | Bit 10: IRQ50S | Description |
|----------------|----------------|--|
| 0 | 0 | An interrupt request is detected at IRQ5 input falling edge (Initial value) |
| | 1 | An interrupt request is detected at IRQ5 input rising edge |
| 1 | 0 | An interrupt request is detected at IRQ5 input low level |
| | 1 | Reserved |

Bits 9 and 8—IRQ4 Sense Select (IRQ41S, IRQ40S): Select whether the interrupt signal to the IRQ4 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 9: IRQ41S | Bit 8: IRQ40S | Description |
|---------------|---------------|--|
| 0 | 0 | An interrupt request is detected at IRQ4 input falling edge (Initial value) |
| | 1 | An interrupt request is detected at IRQ4 input rising edge |
| 1 | 0 | An interrupt request is detected at IRQ4 input low level |
| | 1 | Reserved |

Bits 7 and 6—IRQ3 Sense Select (IRQ31S, IRQ30S): Select whether the interrupt signal to the IRQ3 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 7: IRQ31S | Bit 6: IRQ30S | Description |
|---------------|---------------|--|
| 0 | 0 | An interrupt request is detected at IRQ3 input falling edge (Initial value) |
| | 1 | An interrupt request is detected at IRQ3 input rising edge |
| 1 | 0 | An interrupt request is detected at IRQ3 input low level |
| | 1 | Reserved |

www.DataSheet4U.com

Bits 5 and 4—IRQ2 Sense Select (IRQ21S, IRQ20S): Select whether the interrupt signal to the IRQ2 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 5: IR | RQ21S | Bit 4: IRQ20S | Description |
|-----------|---------|---------------|--|
| 0 | | 0 | An interrupt request is detected at IRQ2 input falling edge (Initial value) |
| | ww.Data | Sheet4U.com | An interrupt request is detected at IRQ2 input rising edge |
| 1 | | 0 | An interrupt request is detected at IRQ2 input low level |
| | | 1 | Reserved |

Bits 3 and 2—IRQ1 Sense Select (IRQ11S, IRQ10S): Select whether the interrupt signal to the IRQ1 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 3: IRQ11S | Bit 2: IRQ10S | Description |
|---------------|---------------|--|
| 0 | 0 | An interrupt request is detected at IRQ1 input falling edge (Initial value) |
| | 1 | An interrupt request is detected at IRQ1 input rising edge |
| 1 | 0 | An interrupt request is detected at IRQ1 input low level |
| | 1 | Reserved |

Bits 1 and 0—IRQ0 Sense Select (IRQ01S, IRQ00S): Select whether the interrupt signal to the IRQ0 pin is detected at the rising edge, at the falling edge, or at the low level.

| Bit 1: IRQ01S | Bit 0: IRQ00S | Description |
|---------------|---------------|--|
| 0 | 0 | An interrupt request is detected at IRQ0 input falling edge (Initial value) |
| | 1 | An interrupt request is detected at IRQ0 input rising edge |
| 1 | 0 | An interrupt request is detected at IRQ0 input low level |
| | 1 | Reserved |

7.3.4 Interrupt Control Register 2 (ICR2)

ICR2 is a 16-bit readable/writable register that sets the detection mode for external interrupt input pins PINT0 to PINT15. This register is initialized to H'0000 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Dat Bit h | eet4 15 om | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------------|-------------------|---------|---------|---------|---------|---------|--------|---------------|
| | PINT15S | PINT14S | PINT13S | PINT14S | PINT11S | PINT10S | PINT9S | PINT8S |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15 to 0—PINT15 to PINT0 Sense Select (PINT15S to PINT0S): Select whether interrupt request signals to PINT15 to PINT0 are detected at the low level or high level.

| Bits 15–0: PINT15S to PINT0S | Description |
|---------------------------------|---|
| 0 | Interrupt requests are detected at low level input to the PINT pin (Initial value) |
| 1 | Interrupt requests are detected at high level input to the PINT pin |

7.3.5 **PINT Interrupt Enable Register (PINTER)**

PINTER is a 16-bit readable/writable register that enables interrupt requests input to external interrupt input pins PINT0 to PINT15. This register is initialized to H'0000 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Data Bit eet4U. 15 m | | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|--|---------|---------|---------|---------|---------|---------|--------|--------|
| | PINT15E | PINT14E | PINT13E | PINT12E | PINT11E | PINT10E | PINT9E | PINT8E |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | PINT7E | PINT6E | PINT5E | PINT4E | PINT3E | PINT2E | PINT1E | PINT0E |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15 to 0—PINT15 to PINT0 Interrupt Enable (PINT15E to PINT0E): Enable or diable interrupt request input to pins PINT15 to PINT0.

| Bits 15–0: PINT15E to PINT0E | Description | |
|---------------------------------|--|-----------------|
| 0 | PINT input interrupt requests disabled | (Initial value) |
| 1 | PINT input interrupt requests enabled | |

When all or some of pins PINT0–PINT15 are not used for interrupt input, bits corresponding to pins not used as interrupt request pins should be cleared to 0.

7.3.6 Interrupt Request Register 0 (IRR0)

IRR0 is an 8-bit register that indicates interrupt requests from external input pins IRQ0 to IRQ5 and PINT0 to PINT15. This register is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Dat Bit he | eet4U 7 com | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------------------|--------------------|--------|-------|-------|-------|-------|-------|-------|
| | PINT0R | PINT1R | IRQ5R | IRQ4R | IRQ3R | IRQ2R | IRQ1R | IRQ0R |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R/W | R/W | R/W | R/W | R/W | R/W |

When clearing an IRQ5R–IRQ0R bit to 0, read the bit while bit set to 1, and then write 0. In this case, 0 should be written only to the bits to be cleared and 1 to the other bits. The contents of the bits to which 1 is written do not change.

Bit 7—PINT0 to PINT7 Interrupt Request (PINT0R): Indicates whether there is interrupt request input to pins PINT0 to PINT7.

Bit 7: PINTOR Description

| 0 | No interrupt request to pins PINT0 to PINT7 | (Initial value) |
|---|---|-----------------|
| 1 | Interrupt to pins PINT0 to PINT7 | |

Bit 6—PINT8 to PINT15 Interrupt Request (PINT1R): Indicates whether there is interrupt request input to pins PINT8 to PINT15.

Bit 6: PINT1R Description

| 0 | No interrupt request input to pins PINT8 to PINT15 | (Initial value) |
|---|--|-----------------|
| 1 | Interrupt request input to pins PINT8 to PINT15 | |

Bit 5—IRQ5 Interrupt Request (IRQ5R): Indicates whether there is interrupt request input to the IRQ5 pin. When edge detection mode is set for IRQ5, an interrupt request is cleared by clearing the IRQ5R bit.

| Bit 5: IRQ5R | Description | |
|--------------|--|-----------------|
| 0 | No interrupt request input to IRQ5 pin | (Initial value) |
| 1 | Interrupt request input to IRQ5 pin | |

Bit 4—IRQ4 Interrupt Request (IRQ4R): Indicates whether there is interrupt request input to the IRQ4 pin. When edge detection mode is set for IRQ4, an interrupt request is cleared by clearing the IRQ4R bit.

| Bit 4: IRQ4R | Description | |
|--------------|--|-----------------|
| 0 | No interrupt request input to IRQ4 pin | (Initial value) |
| 1 www.Datas | Interrupt request input to IRQ4 pin | |

Bit 3—IRQ3 Interrupt Request (IRQ3R): Indicates whether there is interrupt request input to the IRQ3 pin. When edge detection mode is set for IRQ3, an interrupt request is cleared by clearing the IRQ3R bit.

| Bit 3: IRQ3R | Description | |
|--------------|--|-----------------|
| 0 | No interrupt request input to IRQ3 pin | (Initial value) |
| 1 | Interrupt request input to IRQ3 pin | |

Bit 2—IRQ2 Interrupt Request (IRQ2R): Indicates whether there is interrupt request input to the IRQ2 pin. When edge detection mode is set for IRQ2, an interrupt request is cleared by clearing the IRQ2R bit.

| Bit 2: IRQ2R | Description | |
|--------------|--|-----------------|
| 0 | No interrupt request input to IRQ2 pin | (Initial value) |
| 1 | Interrupt request input to IRQ2 pin | |

Bit 1—IRQ1 Interrupt Request (IRQ1R): Indicates whether there is interrupt request input to the IRQ1 pin. When edge detection mode is set for IRQ1, an interrupt request is cleared by clearing the IRQ1R bit.

| Bit 1: IRQ1R | Description | |
|--------------|--|-----------------|
| 0 | No interrupt request input to IRQ1 pin | (Initial value) |
| 1 | Interrupt request input to IRQ1 pin | |

Bit 0—IRQ0 Interrupt Request (IRQ0R): Indicates whether there is interrupt request input to the IRQ0 pin. When edge detection mode is set for IRQ0, an interrupt request is cleared by clearing the IRQ0R bit.

| Bit 0: IRQ0R | Description |
|--------------|-------------|
|--------------|-------------|

| 0 | No interrupt request input to IRQ0 pin | (Initial value) |
|---|--|-----------------|
| 1 | Interrupt request input to IRQ0 pin | |

7.3.7 Interrupt Request Register 1 (IRR1)

IRR1 is an 8-bit read-only register that indicates whether DMAC or IrDA interrupt requests have been generated. This register is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode.

| www.Dat Bit he | eet4U 7 com | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------------------|--------------------|-------|-------|-------|-------|-------|-------|-------|
| | TXI1R | BRI1R | RXI1R | ERI1R | DEI3R | DEI2R | DEI1R | DEI0R |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |

Bit 7—TXI1 Interrupt Request (TXI1R): Indicates whether a TXI1 (IrDA) interrupt request has been generated.

| Bit 7: TXI1 | Description | |
|-------------|--------------------------------------|-----------------|
| 0 | TXI1 interrupt request not generated | (Initial value) |
| 1 | TXI1 interrupt request generated | |

Bit 6—BRI1 Interrupt Request (BRI1R): Indicates whether a BRI1 (IrDA) interrupt request has been generated.

| Bit 6: BRI1R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | BRI1 interrupt request not generated | (Initial value) |
| 1 | BRI1 interrupt request generated | |

Bit 5—RXI1 Interrupt Request (RXI1R): Indicates whether an RXI1 (IrDA) interrupt request has been generated.

Bit 5: RXI1R Description

| 0 | RXI1 interrupt request not generated | (Initial value) |
|---|--------------------------------------|-----------------|
| 1 | RXI1 interrupt request generated | |

Bit 4—ERI1 Interrupt Request (ERI1R): Indicates whether an ERI1 (IrDA) interrupt request has been generated.

Bit 4: ERI1R Description

| 0 | ERI1 interrupt request not generated | (Initial value) |
|---|--------------------------------------|-----------------|
| 1 | ERI1 interrupt request generated | |

Bit 3—DEI3 Interrupt Request (DEI3R): Indicates whether a DEI3 (DMAC) interrupt request has been generated.

Bit 3: DEI3R Description

| | • | |
|---|--------------------------------------|-----------------|
| 0 | DEI3 interrupt request not generated | (Initial value) |
| 1 | DEI3 interrupt request generated | |

Bit 2—DEI2 Interrupt Request (DEI2R): Indicates whether a DEI2 (DMAC) interrupt request has been generated.

| Bit 2: DEI2R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | DEI2 interrupt request not generated | (Initial value) |
| 1 | DEI2 interrupt request generated | |

Bit 1—DEI1 Interrupt Request (DEI1R): Indicates whether a DEI1 (DMAC) interrupt request has been generated.

| Bit 1: DEI1R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | DEI1 interrupt request not generated | (Initial value) |
| 1 | DEI1 interrupt request generated | |

Bit 0—DEI0 Interrupt Request (DEI0R): Indicates whether a DEI0 (DMAC) interrupt request has been generated.

Bit 0: DEI0R Description

| 0 | DEI0 interrupt request not generated | (Initial value) |
|---|--------------------------------------|-----------------|
| 1 | DEI0 interrupt request generated | |

7.3.8 Interrupt Request Register 2 (IRR2)

IRR2 is an 8-bit read-only register that indicates whether an A/D converter or SCIF interrupt request has been generated. This register is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|---|---|------|-------|-------|-------|-------|
| | | | _ | ADIR | TXI2R | BRI2R | RXI2R | ERI2R |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |

Bits 7 to 5—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 4—ADI Interrupt Request (ADIR): Indicates whether an ADI (ADC) interrupt request has been generated.

| Bit 4: | ADIR Description | |
|--------|--|-----------------|
| 0 | www.DataSADI interrupt request not generated | (Initial value) |
| 1 | ADI interrupt request generated | |

Bit 3—TXI2 Interrupt Request (TXI2R): Indicates whether a TXI2 (SCIF) interrupt request has been generated.

| Bit 3: TXI2R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | TXI2 interrupt request not generated | (Initial value) |
| 1 | TXI2 interrupt request generated | |

Bit 2—BRI2 Interrupt Request (BRI2R): Indicates whether a BRI2 (SCIF) interrupt request has been generated.

Bit 2: BRI2R Description

| 0 | BRI2 interrupt request not generated | (Initial value) |
|---|--------------------------------------|-----------------|
| 1 | BRI2 interrupt request generated | |

Bit 1—RXI2 Interrupt Request (RXI2R): Indicates whether an RXI2 (SCIF) interrupt request has been generated.

| Bit 1: RXI2R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | RXI2 interrupt request not generated | (Initial value) |
| 1 | RXI2 interrupt request generated | |

Bit 0—ERI2 Interrupt Request (ERI2R): Indicates whether an ERI2 (SCIF) interrupt request has been generated.

| Bit 0: ERI2R | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | ERI2 interrupt request not generated | (Initial value) |
| 1 | ERI2 interrupt request generated | |

7.4 INTC Operation

7.4.1 Interrupt Sequence

The sequence of interrupt operations is described below. Figure 7.3 is a flowchart of the operations.

- 1. The interrupt request sources send interrupt request signals to the interrupt controller.
- 2. The interrupt controller selects the highest-priority interrupt from the interrupt requests sent, following the priority levels set in interrupt priority registers A to E (IPRA to IPRE). Lower priority interrupts are held pending. If two of these interrupts have the same priority level or if multiple interrupts occur within a single module, the interrupt with the highest default priority or the highest priority within its IPR setting unit (as indicated in tables 7.4 and 7.5) is selected.
- 3. The priority level of the interrupt selected by the interrupt controller is compared with the interrupt mask bits (I3–I0) in the status register (SR) of the CPU. If the request priority level is higher than the level in bits I3–I0, the interrupt controller accepts the interrupt and sends an interrupt request signal to the CPU. When the interrupt controller receives an interrupt, a low level is output from the IRQOUT pin.
- 4. Detection timing: The INTC operates, and notifies the CPU of interrupt requests, in synchronization with the peripheral clock ($P\phi$). The CPU receives an interrupt at a break in instructions.
- 5. The interrupt source code is set in the interrupt event registers (INTEVT and INTEVT2).
- 6. The status register (SR) and program counter (PC) are saved to SSR and SPC, respectively.
- 7. The block bit (BL), mode bit (MD), and register bank bit (RB) in SR are set to 1.
- 8. The CPU jumps to the start address of the interrupt handler (the sum of the value set in the vector base register (VBR) and H'00000600). This jump is not a delayed branch. The interrupt handler may branch with the INTEVT and INTEVT2 register value as its offset in order to identify the interrupt source. This enables it to branch to the handling routine for the individual interrupt source.
- Notes: 1. The interrupt mask bits (I3–I0) in the status register (SR) are not changed by acceptance of an interrupt in the SH7729R.
 - 2. **IRQOUT** outputs a low level until the interrupt request is cleared. However, if the interrupt source is masked by an interrupt mask bit, the **IRQOUT** pin returns to the high level. The level is output without regard to the BL bit.
 - 3. The interrupt source flag should be cleared in the interrupt handler. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag after it has been cleared, then wait for the interval shown in table 7.8 (Time for priority decision and SR mask bit comparison) before clearing the BL bit or executing an RTE instruction.

www.DataSheet4U.com Rev. 5.0, 09/03, page 187 of 806

Figure 7.3 Interrupt Operation Flowchart

7.4.2 Multiple Interrupts

When handling multiple interrupts, an interrupt handler should include the following procedures:

- Branch to a specific interrupt handler corresponding to a code set in INTEVT and INTEVT2. The code in INTEVT and INTEVT2 can be used as a branch-offset for branching to the specific handler.t4U.com
- 2. Clear the cause of the interrupt in each specific handler.
- 3. Save SSR and SPC to memory.
- 4. Clear the BL bit in SR, and set the accepted interrupt level in the interrupt mask bits in SR.
- 5. Handle the interrupt.
- 6. Execute the RTE instruction.

When these procedures are followed in order, an interrupt of higher priority than the one being handled can be accepted after clearing BL in step 4. Figure 7.3 shows a sample interrupt operation flowchart.

7.5 Interrupt Response Time

The time from generation of an interrupt request until interrupt exception handling is performed and fetching of the first instruction of the exception handler is started (the interrupt response time) is shown in table 7.8. Figure 7.4 shows an example of pipeline operation when an IRL interrupt is accepted. When SR.BL is 1, interrupt exception handling is masked, and is kept waiting until completion of an instruction that clears BL to 0.

| | Number of States | | | | |
|--|---|-------------------------------------|----------------------------|---|---|
| Item | NMI | IRQ | PINT | Peripheral Modules | Notes |
| Time for priority decision and SR Sheet mask bit comparison | 0.5 × lcyc 4+ 0.5 × Bcyc + 0.5 × Pcyc | 0.5 × lcyc + 1 × Bcyc + 4.5 × | 0.5 × lcyc + 3.5 × Pcyc | $0.5 \times lcyc$ + $1.5 \times Pcyc^{*5}$ | |
| | | Pcyc ^{*4} | | $\begin{array}{c} 0.5 \times \text{lcyc} \\ \textbf{+} \ 3 \times \text{Pcyc}^{*6} \end{array}$ | _ |
| Wait time until end of sequence being executed by CPU | X (≥ 0) × Icyc | X (≥ 0) × Icyc | X (≥ 0) × Icyc | X (≥ 0) × Icyc | Interrupt exception handling is kept waiting until the executing instruc- tion ends. If the number of instruc- tion execution states is S^{*1} , the maximum wait time is: $X = S - 1$. However, if BL is set to 1 by instru- ction execution or by an exception, interrupt exception handling is deferred until completion of an instruction that clears BL to 0. If the following instruction masks interrupt exception handling, the handling may be further deferred. |
| Time from interrupt exception handling (save of SR and PC) until fetch of first instruction of | 5 × Icyc | 5 × Icyc | 5 × Icyc | 5 × Icyc | |

Table 7.8 Interrupt Response Time

exception handler is

started

| ltem | | NMI | IRQ | PINT | Peripheral Modules | - Notes | |
|-------------------------------|-------------------------------|---|---|--|--|---|--|
| Response time | | (5.5 + X) × lcyc + 0.5 × Bcyc ⊔+0.5 × Pcyc | (5.5 + X) × lcyc + 1 × Bcyc + $4.5 \times Pcyc^{*4}$ | (5.5 + X) × lcyc + 3.5 × Pcyc ^{*5} | (5.5 + X) × Icyc + 1.5 × Pcyc ^{∗5} | | |
| | | | | | (5.5 + X) × lcyc + 3 × Pcyc ^{*6} | _ | |
| | Minimum case ^{*2} | 7.5 | 16.5 | 12.5 | 8.5 ^{*5} /11.5 ^{*6} | At 60-MHz (CKIO = 30) operation: 0.13–0.28 μs | |
| Maximum case ^{*3} | 8.5 + S | 26.5 + S | 18.5 + S | 10.5 + S ^{*5} 16.5 + S ^{*6} | At 60-MHz (CKIO = 15) operation: 0.26–0.56 µs (in case of operand cache-hit) | | |
| | | | | | | At 60-MHz (CKIO = 15) operation: $0.29-0.59 \ \mu s$ (when external memory access is performed with wait = 0) | |

Number of States

Icyc: Duration of one cycle of internal clock supplied to CPU.

Bcyc: Duration of one CKIO cycle.

Pcyc: Duration of one cycle of peripheral clock supplied to peripheral modules.

Notes: 1. S also includes the memory access wait time.

The processing requiring the maximum execution time is LDC.L @Rm+, SR. When the memory access is a cache-hit, this requires seven instruction execution cycles. When the external access is performed, the corresponding number of cycles must be added. There are also instructions that perform two external memory accesses; if the external memory access is slow, the number of instruction execution cycles will increase accordingly.

- 2. The internal clock:CKIO:peripheral clock ratio is 2:1:1.
- 3. The internal clock:CKIO:peripheral clock ratio is 4:1:1.
- 4. IRQ mode
- 5. Modules: TMU, RTC, SCI, WDT, REFC
- 6. Modules: DMAC, ADC, IrDA, SCIF

Figure 7.4 Example of Pipeline Operations when IRL Interrupt is Accepted

Section 8 User Break Controller

8.1 Overview

The user break controller (UBC) provides functions that simplify program debugging. Break conditions are set in the UBC and a user break is generated according to the conditions of the bus cycle generated by the CPU or on-chip DMAC. The breakpoint check function monitors instruction fetches and operand read/writes, generating a variable combination of pre-execution instruction fetch, post-execution instruction fetch, and post-execution operand access breakpoint traps under designated read/write conditions.

This function makes it easy to design an effective self-monitoring debugger, enabling the chip to debug programs without using an in-circuit emulator.

8.1.1 Features

The UBC has the following features:

• The following break comparison conditions can be set.

Number of break channels: two channels (channels A and B) User break can be requested as either the independent or sequential condition on channels A and B (sequential break setting: when a channel A break condition match is followed by a channel B break condition match, and both matches do not occur in the same bus cycle).

- Address (Compares 40 bits comprising a 32-bit logical address prefixed with an ASID address. Comparison bits are maskable in 32-bit units; user can mask addresses at lower 12 bits (4-k page), lower 10 bits (1-k page), or any size of page, etc.)
 One of four address buses (logic address bus (LAB), internal address bus (IAB), X-memory address bus (XAB), or Y-memory address bus (YAB)) can be selected.
- Data (only on channel B, 32-bit maskable)
 One of the four data buses (logic data bus (LDB), internal data bus (IDB), X-memory data bus (XDB), or Y-memory data bus (YDB)) can be selected.
- Bus master: CPU or DMAC cycle
- Bus cycle: Instruction fetch or data access
- Read/write
- Operand size: Byte, word, or longword
- User break is generated upon satisfying break conditions. A user-designed user-break condition exception handling routine can be run.
- In an instruction fetch cycle, break setting before or after instruction execution can be set.
- Breaks can be specified for on-chip I/O accesses or LDTLB instruction execution in ASE mode.

www.DataSheet4U.com Rev. 5.0, 09/03, page 193 of 806

- The number of repetitions can be specified as a break condition. (channel B only)
- Maximum repetitions for the break condition: $2^{12} 1$ times.
- Eight pairs of branch source/destination buffers.

8.2.1 Break Address Register A (BARA)

BARA is a 32-bit readable/writable register that specifies the address used as a break condition in channel A. BARA is initialized to H'00000000 by a power-on reset.

Bits 31 to 0—Break Address A31 to A0 (BAA31 to BAA0): Store the address on the LAB or IAB specifying break conditions of channel A.

8.2.2 Break Address Mask Register A (BAMRA)

BAMRA is a 32-bit readable/writable register that specifies bits masked in the break address specified by BARA. BAMRA is initialized to H'00000000 by a power-on reset.

Bits 31 to 0—Break Address Mask Register A31 to A0 (BAMA31 to BAMA0): Specify bits masked in the channel A break address bits specified by BARA (BAA31–BAA0).

| Bits 31–0: BAMAn | Description |
|---------------------|--|
| 0 | Break address bit BAAn of channel A is included in the break condition (Initial value) |
| 1 | Break address bit BAAn of channel A is masked and is not included in the break condition |
| n = 31–0 | |

8.2.3 Break Bus Cycle Register A (BBRA)

Break bus cycle register A (BBRA) is a 16-bit readable/writable register that specifies (1) CPU cycle or DMAC cycle, (2) instruction fetch or data access, (3) read or write, and (4) operand size in the break conditions of channel A. BBRA is initialized to H'0000 by a power-on reset.

Bits 15 to 8—Reserved: These bits are always read as 0. The write value should always be 0.

Bits 7 and 6—CPU Cycle/DMAC Cycle Select A (CDA1, CDA0): Select a CPU cycle or DMAC cycle as the bus cycle of the channel A break condition.

| Bit 7: CDA1 | Bit 6: CDA0 | Description | |
|-------------|-------------|---------------------------------------|-----------------|
| 0 | 0 | Condition comparison is not performed | (Initial value) |
| * | 1 | Break condition is CPU cycle | |
| 1 | 0 | Break condition is DMAC cycle | |
| | | | |

Note: * Don't care

Bits 5 and 4—Instruction Fetch/Data Access Select A (IDA1, IDA0): Select an instruction fetch cycle or data access cycle as the bus cycle of the channel A break condition.

| Bit 5: IDA1 | Bit 4: IDA0 | Description | |
|-------------|-------------|--|-----------------|
| 0 | 0 | Condition comparison is not performed | (Initial value) |
| | 1 | Break condition is instruction fetch cycle | |
| 1 | 0 | Break condition is data access cycle | |
| | 1 | Break condition is instruction fetch cycle or da | ta access cycle |

Bits 3 and 2—Read/Write Select A (RWA1, RWA0): Select a read cycle or write cycle as the bus cycle of the channel A break condition.

8.2.4 Break Address Register B (BARB)

BARB is a 32-bit readable/writable register that specifies the address used as a break condition in channel B. Control bits XYE and XYS in BBRB select an address bus for break condition B. If XYE is 0, then BARB specifies the break address on the logic or internal bus, LAB or IAB. If XYE is 1, then BAB31–16 specifies the break address on XAB (bits 15–1) and BAB15–0 specifies the break address on YAB (bits 15–1). However, one of two address buses must be chosen for the break. BARB is initialized to H'00000000 by a power-on reset.

| | BAB31–16 | BAB15–0 |

8.2.6 Break Data Register B (BDRB)

BDRB is a 32-bit readable/writable register. The control bits XYE and XYS in BBRB select a data bus for break condition B. If XYE is 0, then BDRB specifies the break data on LDB or IDB. If XYE is 1, then BDB31–16 specifies the break data on XDB (bits 15–0) and BDB15–0 specifies the break data on YDB (bits 15–0). However, one of two data buses must be chosen for the break. BDRB is initialized to H'00000000 by a power-on reset.

| | BDB31–16 | BDB15–0 |

| XYE = 0 | Mask L(I) DB31–16 | Mask L(I) DB15–0 |
| XYE = 1 | Mask XDB15–0 (XYS = 0) | Mask YDB15–0 (XYS = 1) |

Bits 31-0:

| BDMBn | Description |
|-------|---|
| 0 | Break data BDBn of channel B is included in the break condition (Initial value) |
| 1 | Break data BDBn of channel B is masked and is not included in the break condition |

n = 31–0

Notes: 1. Specify an operand size when including the value of the data bus in the break condition.

2. When a byte size is selected as a break condition, the break data must be set in bits 15-8 in BDRB for an even break address and bits 7-0 for an odd break address. Other bits have no influence on a break condition.

8.2.8 Break Bus Cycle Register B (BBRB)

Break bus cycle register B (BBRB) is a 16-bit readable/writable register that specifies (1) logic or internal bus (L or I bus), X bus, or Y bus, (2) CPU cycle or DMAC cycle, (3) instruction fetch or data access, (4) read/write, and (5) operand size in the break conditions of channel B. BBRB is initialized to H'0000 by a power-on reset.

Bits 15 to 10—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 9—X/Y Memory Bus Enable (XYE): Selects the logic or internal bus (L or I bus) or X/Y memory bus as the bus of the channel B break condition.

| Bit 9: XYE | Description |
|------------|---|
| 0 | Internal bus (I bus) selected for the channel B break condition |
| 1 | X/Y memory bus (X/Y bus) selected for the channel B break condition |

Bit 8—X or Y Memory Bus Select (XYS): Selects the X bus or the Y bus as the bus of the channel B break condition.

| Bit 8: XYS | Description |
|------------|--|
| 0 | X bus selected for the channel B break condition |
| 1 | Y bus selected for the channel B break condition |

www.DataSheet4U.com Rev. 5.0, 09/03, page 205 of 806

Bits 7 and 6—CPU Cycle/DMAC Cycle Select B (CDB1, CDB0): Select a CPU cycle or

DMAC cycle as the bus cycle of the channel B break condition.

| Bit 7: CDB1 | Bit 6: CDB0 | Description | |
|-------------|-----------------------------------|---------------------------------------|-----------------|
| 0 | 0 | Condition comparison is not performed | (Initial value) |
| * | 1 http://www.internationalized | Break condition is CPU cycle | |
| 1 | 0 | Break condition is DMAC cycle | |

Note: * Don't care.

Bits 5 and 4—Instruction Fetch/Data Access Select B (IDB1, IDB0): Select an instruction fetch cycle or data access cycle as the bus cycle of the channel B break condition.

| Bit 5: IDB1 | Bit 4: IDB0 | Description | |
|-------------|-------------|---|-----------------|
| 0 | 0 | Condition comparison is not performed | (Initial value) |
| | 1 | Break condition is instruction fetch cycle | |
| 1 | 0 | Break condition is data access cycle | |
| | 1 | Break condition is instruction fetch cycle or dat | a access cycle |

Bits 3 and 2—Read/Write Select B (RWB1, RWB0): Select a read cycle or write cycle as the bus cycle of the channel B break condition.

| Bit 3: RWB1 | Bit 2: RWB0 | Description | |
|-------------|-------------|--|-----------------|
| 0 | 0 | Condition comparison is not performed | (Initial value) |
| | 1 | Break condition is read cycle | |
| 1 | 0 | Break condition is write cycle | |
| | 1 | Break condition is read cycle or write cycle | |

Bits 1 and 0—Operand Size Select B (SZB1, SZB0): Select the operand size of the bus cycle for the channel B break condition.

| Bit 1: SZB1 | Bit 0: SZB0 | Description |
|-------------|-------------|---|
| 0 | 0 | Break condition does not include operand size (Initial value) |
| | 1 | Break condition is byte access |
| 1 | 0 | Break condition is word access |
| | 1 | Break condition is longword access |

| R/W: | R/W | R/W | R | R | R/W | R | R | R/W |

BRCR sets the following conditions:

- 1. Use of channels A and B as two independent channel conditions or as a sequential condition
- 2. Break setting before or after instruction execution
- 3. Break setting by the number of execution times
- 4. Determination of whether to include data bus on channel B in comparison conditions
- 5. Enabling of PC trace
- 6. Enabling of ASID check

The break control register (BRCR) is a 32-bit readable/writable register that has break condition match flags and bits for setting a variety of break conditions.

BRCR is initialized to H'00000000 by a power-on reset.

www.DataSheet4U.com Rev. 5.0, 09/03, page 207 of 806

Bits 31 to 22—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 21—Break ASID Mask A (BASMA): Specifies whether or not channel A break bits ASID7 to ASID0 (BASA7 to BASA0) set in BASRA are masked.

Bit 21: BASMA Description

| 0 | www.Data All BASRA bits are included in break condition, ASID is checked | (Initial value) |

| 1 | No BASRA bits are included in break condition, ASID is not checked | ed . |

Bit 20—Break ASID Mask B (BASMB): Specifies whether or not channel B break bits ASID7 to ASID0 (BASB7 to BASB0) set in BASRB are masked.

Bit 20: BASMB Description

| 0 | All BASRB bits are included in break condition, ASID is checked (Initial value) |
|---|---|
| 1 | No BASRB bits are included in break condition, ASID is not checked |

Bits 19 to 16—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 15—CPU Condition Match Flag A (SCMFCA): When the CPU bus cycle condition in the break conditions set for channel A is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 to this bit.

Bit 15: SCMFCA

Description

| 0 | CPU cycle condition for channel A is not matched | (Initial value) |
|---|--|-----------------|
| 1 | CPU cycle condition for channel A is matched | |

Bit 14—CPU Condition Match Flag B (SCMFCB): When the CPU bus cycle condition in the break conditions set for channel B is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 to this bit.

| Bit 14: SCMFCB | Description | |
|-------------------|--|-----------------|
| | CPU cycle condition for channel B is not matched | (Initial value) |
| 1 | CPU cycle condition for channel B is matched | |

Bit 13—DMAC Condition Match Flag A (SCMFDA): When the on-chip DMAC bus cycle condition in the break conditions set for channel A is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 to this bit.

| Bit 13 SCM | | |
|---------------|---|-----------------|
| 0 | www.DataSIDMAC cycle condition for channel A is not matched | (Initial value) |
| 1 | DMAC cycle condition for channel A is matched | |

Bit 12—DMAC Condition Match Flag B (SCMFDB): When the on-chip DMAC bus cycle condition in the break conditions set for channel B is satisfied, this flag is set to 1 (not cleared to 0). In order to clear this flag, write 0 to this bit.

| Bit 12: SCMFDB | Description | |
|-------------------|---|-----------------|
| 0 | DMAC cycle condition for channel B is not matched | (Initial value) |
| 1 | DMAC cycle condition for channel B is matched | |

Bit 11—PC Trace Enable (PCTE): Enables a PC trace.

| Bit 11: PCTE | Description | |
|--------------|-------------------|-----------------|
| 0 | PC trace disabled | (Initial value) |
| 1 | PC trace enabled | |

Bit 10—PC Break Select A (PCBA): Selects the break timing of the instruction fetch cycle for channel A as before or after instruction execution.

| Bit 10: PCBA | Description | |
|--------------|---|-----------------|
| 0 | PC break of channel A is set before instruction execution | (Initial value) |
| 1 | PC break of channel A is set after instruction execution | |

Bits 9 and 8—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 7—Data Break Enable B (DBEB): Selects whether or not the data bus condition is included in the channel B break condition.

| Bit 7: DBEB | Description | |
|-------------|--|-----------------|
| 0 | Data bus condition not included in channel B condition | (Initial value) |
| 1 | Data bus condition included in channel B condition | |

Bit 6—PC Break Select B (PCBB): Selects the break timing of the instruction fetch cycle for channel B as before or after instruction execution.

| Bit 6: PCBB | Description | |
|-------------|---|-----------------|
| 0 | PC break of channel B is set before instruction execution | (Initial value) |
| 1 | PC break of channel B is set after instruction execution | |

Bits 5 and 4—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 3—Sequence Condition Select (SEQ): Selects two conditions of channels A and B as independent or sequential.

| Bit 3: SEQ | Description | |
|------------|---|-----------------|
| 0 | Channels A and B are compared as independent conditions | (Initial value) |
| 1 | Channels A and B are compared as a sequential condition | |

Bits 2 and 1—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 0—Execution Times Break Enable (ETBE): Enables the execution-times break condition on channel B only. If this bit is 1 (break enabled), a user break is issued when the number of break conditions matches the number of execution times specified by the BETR register.

| Bit 0: ETBE | Description | |
|-------------|---|-----------------|
| 0 | Execution-times break condition is masked on channel B | (Initial value) |
| 1 | Execution-times break condition is enabled on channel B | |

8.2.10 Break Execution Times Register (BETR)

www.DataSheet4U.com

When the execution-times break condition of channel B is enabled, this register specifies the number of execution times to make the break. The maximum number is $2^{12} - 1$ times. BETR is initialized to H'0000 by a power-on reset. When a break condition is satisfied, the BETR value is decremented by 1. A break is issued when the break condition is satisfied after the BETR value reaches H'0001. Bits 15–12 are always read as 0, and 0 should always be written to these bits.

8.2.11 Branch Source Register (BRSR)

Note: * Undefined

BRSR is a 32-bit read-only register that stores the last fetched address before a branch and the pointer (3 bits) which indicates the number of cycles from fetch to execution for the last executed instruction. BRSR has a flag bit that is set to 1 when a branch occurs. This flag bit is cleared to 0 when BRSR is read, and also is initialized by a power-on reset or manual reset. Other bits are not initialized by a reset. Four BRSR registers have a queue structure and the stored register is shifted every branch.

Bit 31—BRSR Valid Flag (SVF): Indicates whether the address and the pointer that indicates the branch source address can be calculated. When a branch source address is fetched, this flag is set to 1. This flag is cleared to 0 by reading BRSR.

| Bit 31: SVF | Description | |
|-------------|--------------------------------|-----------------|
| 0 | BRSR register value is invalid | (Initial value) |
| 1 www.Dat | BRSR register value is valid | |

Bits 30 to 28—Instruction Decode Pointer (PID2 to PID0): PID is a 3-bit binary pointer (0–7). These bits indicate the instruction buffer number which stores the last instruction executed before a branch.

| Bits 30 to 28: PID | Description |
|-----------------------|---|
| Even | PID indicates the instruction buffer number |
| Odd | PiD+2 indicates the instruction buffer number |

Bits 27 to 0—Branch Source Address (BSA27 to BSA0): These bits store the last address fetched before a branch.

8.2.12 Branch Destination Register (BRDR)

BRDR is a 32-bit read-only register that stores the branch destination fetch address. BRDR has a flag bit that is set to 1 when a branch occurs. This flag bit is cleared to 0 when BRDR is read, and is also initialized by a power-on reset or manual reset. Other bits are not initialized by a reset. Four BRDR registers have a queue structure, and the stored register is shifted every branch.

Bit 31—BRDR Valid Flag (DVF): Indicates whether a branch destination address is stored. When a branch destination address is fetched, this flag is set to 1. This flag is set to 0 by reading BRDR.

| Bit 31: DVF | Description | |
|-------------|--------------------------------|-----------------|
| 0 | BRDR register value is invalid | (Initial value) |
| 1 | BRDR register value is valid | |

Bits 30 to 28—Reserved: These bits are always read as 0. The write value should always be 0.

Bits 27 to 0—Branch Destination Address (BDA27 to BDA0): These bits store the first address fetched after a branch. www.DataSheet4U.com Rev. 5.0, 09/03, page 213 of 806

8.2.13 Break ASID Register A (BASRA)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------------|----------|-------|-------|-------|-------|-------|-------|-------|
| | BASA7 | BASA6 | BASA5 | BASA4 | BASA3 | BASA2 | BASA1 | BASA0 |

| www.DataShe | et40.com | R/W |
| Note: * Undefined | | | | | | | | |

Break ASID register A (BASRA) is an 8-bit readable/writable register that specifies the ASID that serves as the break condition for channel A. It is not initialized by a reset. It is located in CCN.

Bits 7 to 0—Break ASID A7 to 0 (BASA7 to BASA0): These bits store the ASID (bits 7 to 0) that is the channel A break condition.

8.2.14 Break ASID Register B (BASRB)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | BASB7 | BASB6 | BASB5 | BASB4 | BASB3 | BASB2 | BASB1 | BASB0 |
| Initial value: | * | * | * | * | * | * | * | * |
| R/W: | R/W |
| Note: * Undefined | | | | | | | | |

Break ASID register B (BASRB) is an 8-bit readable/writable register that specifies the ASID that serves as the break condition for channel B. It is not initialized by a reset. It is located in CCN.

Bits 7 to 0—Break ASID A7 to 0 (BASB7 to BASB0): These bits store the ASID (bits 7 to 0) that is the channel B break condition.

8.3 **Operation Description**

8.3.1 Flow of the User Break Operation

The flow from setting of break conditions to user break exception processing is described below:

- 1. The break addresses and the corresponding ASIDs are loaded in the break address registers (BARA and BARB) and break ASID registers (BASRA and BASRB in CCN). The masked addresses are set in the break address mask registers (BAMRA and BAMRB). The break data is set in the break data register (BDRB). The masked data is set in the break data mask register (BDMRB). The breaking bus conditions are set in the break bus cycle registers (BBRA and BBRB). Three groups of the BBRA and BBRB (CPU cycle/DMAC cycle select, instruction fetch/data access select, and read/write select) are each set. No user break will be generated if even one of these groups is set with 00. The respective conditions are set in the bits of BRCR.
- 2. When the break conditions are satisfied, the UBC sends a user break request to the interrupt controller. The break type will be sent to the CPU indicating instruction fetch, pre/post instruction break, data access break, or on-chip I/O access/LDTLB break. When conditions match, the CPU condition match flags (SCMFCA and SCMFCB) and DMAC condition match flags (SCMFDA and SCMFDB) for the respective channels are set.
- 3. The appropriate condition match flags (SCMFCA, SCMFDA, SCMFCB, and SCMFDB) can be used to check if the set conditions match or not. The matching of the conditions sets flags, but they are not reset. 0 must first be written to them before they can be used again.
- 4. There is a chance that a data access break and its following instruction fetch break will occur around the same time; there will be only one break request to the CPU, but these two break channel match flags could be both set.

8.3.2 Break on Instruction Fetch Cycle

- 1. When CPU/instruction fetch/read/word or longword is set in the break bus cycle registers (BBRA/BBRB), the break condition becomes the CPU instruction fetch cycle. Whether it then breaks before or after execution of the instruction can then be selected with the PCBA/PCBB bits in the break control register (BRCR) for the appropriate channel.
- 2. An instruction set for a break before execution breaks when it is confirmed that the instruction has been fetched and will be executed. This means this feature cannot be used on instructions fetched by overrun (instructions fetched at a branch or during an interrupt transition, but not to be executed). When this kind of break is set for the delay slot of a delay branch instruction, the break is generated prior to execution of the instruction that then first accepts the break. Meanwhile, breaks set for pre-instruction-break on a delay slot instruction and post-instruction-break on a SLEEP instruction are also prohibited.

www.DataSheet4U.com Rev. 5.0, 09/03, page 215 of 806

- 3. When the condition is specified to occur after execution, the instruction set with the break condition is executed and then the break is generated prior to the execution of the next instruction. As with pre-execution breaks, this cannot be used with overrun fetch instructions. When this kind of break is set for a delay branch instruction, the break is generated at the instruction that then first accepts the break.
- 4. When an instruction fetch cycle is set for channel B, break data register B (BDRB) is ignored. There is thus no need to set break data for an instruction fetch cycle break.

8.3.3 Break by Data Access Cycle

- 1. The memory cycle in which a CPU data access break occurs depend on the instruction.
- 2. The relationship between the data access cycle address and the comparison condition for operand size is shown in table 8.2:

| Access Size | Address Compared |
|-------------|--|
| Longword | Compares break address register bits 31–2 to address bus bits 31–2 |
| Word | Compares break address register bits 31–1 to address bus bits 31–1 |
| Byte | Compares break address register bits 31–0 to address bus bits 31–0 |

 Table 8.2
 Data Access Cycle Addresses and Operand Size Comparison Conditions

This means that when address H'00001003 is set without specifying the size condition, for example, the bus cycle in which the break condition is satisfied is as follows (where other conditions are met).

Longword access at H'00001000 Word access at H'00001002 Byte access at H'00001003

3. When the data value is included in the break condition on channel B:

When the data value is included in the break condition, longword, word, or byte is specified as the operand size in the break bus cycle registers (BBRA and BBRB). When data values are included in break conditions, a break is generated when the address conditions and data conditions both match. To specify byte data for this case, set the same data in two bytes at bits 15–8 and bits 7–0 of the break data register B (BDRB) and break data mask register B (BDMRB). When word or byte is set, bits 31–16 of BDRB and BDMRB are ignored.

4. When the DMAC data access is included in the break condition: When the address is included in the break condition on DMAC data access, the operand size of the basel base of the break condition on DMAC data access, the operand size of

the break bus cycle registers (BBRA and BBRB) should be byte, word, or no specified operand size. When the data value is included, select either byte or word.

8.3.4 Break on X/Y-Memory Bus Cycle

- The break condition on an X/Y-memory bus cycle is specified only in channel B. If XYE in BBRB is set to 1, break address and break data on the X/Y-memory bus are selected. At this time, select the X-memory bus or Y-memory bus by specifying XYS in BBRB. The break condition cannot include both X-memory and Y-memory at the same time. The break condition is applied to X/Y-memory bus cycles by specifying CPU/data access/read or write/word or no specified operand size in the break bus cycle register B (BBRB).
- 2. When X-memory address is selected as the break condition, specify the X-memory address in the upper 16 bits of BARB and BAMRB. When Y-memory address is selected, specify the Y-memory address in the lower 16 bits. Specification of X/Y-memory data is the same for BDRB and BDMRB.

8.3.5 Sequential Break

- 1. When SEQ in BRCR is set to 1, the sequential break is issued when the channel B break condition matches after the channel A break condition matches. A user break is ignored even if the channel B break condition matches before the channel A break condition matches. When channel A and B conditions match at the same time, a sequential break is not issued.
- 2. In sequential break specification, the internal/X/Y bus can be selected and the execution times break condition can be also specified. For example, when the execution times break condition is specified, the break condition is satisfied by a channel B condition match with BETR = H'0001 after a channel A condition match.

8.3.6 Value of Saved Program Counter

When a break occurs, PC is saved to SPC in user breaks but saved to a fixed address (H'FD000000) in the ASE space in an ASE break. The PC value saved is as follows depending on the type of break.

- When instruction fetch (before instruction execution) is specified as a break condition: The value of the program counter (PC) saved is the address of the instruction that matches the break condition. The fetched instruction is not executed, and a break occurs before it.
- 2. When instruction fetch (after instruction execution) is specified as a break condition: The PC value saved is the address of the instruction to be executed following the instruction in which the break condition matches. The fetched instruction is executed, and a break occurs before execution of the next instruction.
- 3. When data access (address only) is specified as a break condition: The PC value is the address of the instruction to be executed following the instruction that matched the break condition. The instruction that matched the condition is executed and the break occurs before the next instruction is executed.

www.DataSheet4U.com Rev. 5.0, 09/03, page 217 of 806

4. When data access (address + data) is specified as a break condition:

The PC value is the start address of the instruction that follows the instruction already executed when break processing started. When a data value is added to the break conditions, the place where the break will occur cannot be specified exactly. The break will occur before the execution of an instruction fetched in the vicinity of the data access where the break occurred.

www.DataSheet4U.com

8.3.7 PC Trace

- 1. A PC trace is started by setting the PC trace enable bit (PCTE) to 1 in BRCR. When a branch (branch instruction, repeat, interrupt) occurs, an address that enables the branch source address to be calculated and the branch destination address are stored in the branch source register (BRSR) and branch destination register (BRDR). The branch destination instruction fetch address is stored in BRDR, while the last instruction fetch address before the branch is stored in BRSR. The branch flag register (BRFR) holds a pointer that indicates the relationship to the instruction executed immediately before the branch.
- 2. The address of the instruction executed immediately before the branch can be calculated from the address stored in BRSR and the pointer stored in BRFR. If the address stored in BRSR is BSA, the pointer stored in BRFR is PID, and the address prior to the branch is IA, then IA = $BSA 2 \times PID$.

With this equation, caution is required in the case where an interrupt (branch) is executed before the branch destination instruction is executed. In the example in figure 8.2, the address of instruction "Exec" executed immediately before the branch is calculated using the equation IA = BSA – $2 \times PID$. However, if branch "branch" has a delay slot and the branch destination is address 4n + 2, branch destination address "Dest" specified by the branch instruction is stored in BRSR. Therefore, the equation IA = BSA – $2 \times PID$ does not apply in this case, and this PID is invalid. In this case only, BSA is at the 4n + 2 boundary, classified as shown in table 8.3.

Figure 8.2 When Interrupt Occurs before Branch Instruction Is Executed

| Branch | Branch Destination (Dest) | BSA | Branch Source Address Calculable by Means of BRSR and BRFR |
|----------|---------------------------|--------|---|
| Delay | 4n | 4n | $Exec = IA = BSA - 2 \times PID$ |
| | Data4hha=24U.com | 4n + 2 | Dest = BSA |
| No delay | 4n or 4n + 2 | 4n | $Exec = IA = BSA - 2 \times PID$ |

Table 8.3BSA Values Stored in Exception Handling before Execution of Branch
Destination Instruction

If PID is an odd number, the value incremented by 2 indicates the instruction buffer, but the equations in the table do not take this into account. Therefore, the calculation can be performed using the values of BSA stored in BRSR and PID stored in BRFR.

- 3. The location indicated by IA, the address prior to the branch, depends on the type of branch.
 - a. Branch instruction: Branch instruction address
 - b. Repeat loop: Second-before-last instruction of the repeat loop

```
Repeat_Start: inst (1) ;---->BRDR
inst (2) ;
inst (n-1) ;---->Address calculated from BRSR and BRFR
Repeat End: inst (n) ;
```

c. Interrupt: Instruction executed immediately before the interrupt The start address of the interrupt routine is stored in BRDR.

In a repeat loop consisting of no more than three instructions, an instruction fetch cycle is not generated. A PC trace is invalid, since the branch destination address is unknown.

4. BRSR, BRDR, and BRFR have a four-queue structure. When reading addresses stored in a PC trace, reads are performed from the head of the queue. BRFR, BRSR, and BRDR are read in that order. After BRDR is read, the queue shifts by one. BRSR and BRDR should be read by longword access. Also, the PC trace has a trace pointer, which initially points to the bottom of the queues. The first pair of branch addresses will be stored at the bottom of the queues, then push up when next pairs come into the queues. The trace pointer will points to the next branch address to be executed, unless it got push out of the queues. When the branch address has been executed, the trace pointer will shift down to next pair of addresses, until it reaches the bottom of the queues. After switching the PCTE bit (in BRCR) off and on, the values in the queues are invalid. The read pointer stay at the position before PCTE is switched, but the trace pointer restart at the bottom of the queues.

8.3.8 Examples of Use

Break Condition Specified for CPU Instruction Fetch Cycle

1. Register specifications

BARA = H'00000404, BAMRA = H'00000000, BBRA = H'0054, BARB = H'00008010, BAMRB = H'00000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300400

Specified conditions: Channel A/channel B independent mode

 Channel A Address: H'00000404, Address mask: H'00000000
 Bus cycle: CPU/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

No ASID check is included

• Channel B

| Address: | H'00008010, Address mask: H'00000006 |
|------------|---|
| Data: | H'0000000, Data mask: H'00000000 |
| Bus cycle: | CPU/instruction fetch (before instruction execution)/read (operand size is not included in the condition) |

No ASID check is included

A user break occurs after the instruction at address H'00000404 is executed or before instructions at addresses H'00008010 to H'00008016 are executed.

2. Register specifications

BARA = H'00037226, BAMRA = H'0000000, BBRA = H'0056, BARB = H'0003722E, BAMRB = H'0000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000008, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B sequential mode

• Channel A

Address: H'00037226, Address mask: H'00000000, ASID = H'80

Bus cycle: CPU/instruction fetch (before instruction execution)/read/word

• Channel B

| Address: | H'0003722E, Address mask: H'00000000, ASID = H'70 |
|------------|--|
| Data: | H'00000000, Data mask: H'000000000 |
| Bus cycle: | $CPU/instruction\ fetch\ (before\ instruction\ execution)/read/word$ |

The instruction with ASID = H'80 and address H'00037226 is executed, and a user break occurs before the instruction with ASID = H'70 and address H'0003722E is executed.

www.DataSheet4U.com

3. Register specifications

BARA = H'00027128, BAMRA = H'00000000, BBRA = H'005A, BARB = H'00031415, BAMRB = H'00000000, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'000000000, BRCR = H'00300000

Specified conditions: Channel A/channel B independent mode

- Channel A
 Address: H'00027128, Address mask: H'00000000
 Bus cycle: CPU/instruction fetch (before instruction execution)/write/word No ASID check is included
- Channel B

Address: H'00031415, Address mask: H'00000000

- Data: H'0000000, Data mask: H'00000000
- Bus cycle: CPU/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

No ASID check is included

On channel A, no user break occurs since an instruction fetch is not a write cycle. On channel B, no user break occurs since an instruction fetch is performed for an even address.

4. Register specifications

BARA = H'00037226, BAMRA = H'00000000, BBRA = H'005A, BARB = H'0003722E, BAMRB = H'00000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000008, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B sequential mode

- Channel A Address: H'00037226, Address mask: H'00000000, ASID: H'80 Bus cycle: CPU/instruction fetch (before instruction execution)/write/word
 Channel B
 - Address:H'0003722E, Address mask: H'00000000, ASID: H'70Data:H'00000000, Data mask: H'00000000Bus cycle:CPU/instruction fetch (before instruction execution)/read/word

Since the instruction fetch is not a write cycle on channel A, a sequential condition is not matched. Therefore, no user break occurs.

www.DataSheet4U.com Rev. 5.0, 09/03, page 221 of 806

5. Register specifications

BARA = H'00000500, BAMRA = H'0000000, BBRA = H'0057, BARB = H'00001000, BAMRB = H'00000000, BBRB = H'0057, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300001, BETR = H'0005

Specified conditions: Channel A/channel B independent mode

| • | Channel A | neet4U.com |
|---|------------|--|
| | Address: | H'00000500, Address mask: H'00000000 |
| | Bus cycle: | CPU/instruction fetch (before instruction execution)/read/longword |
| • | Channel B | |
| | Address: | H'00001000, Address mask: H'00000000 |
| | Data: | H'0000000, Data mask: H'00000000 |
| | Bus cycle: | CPU/instruction fetch (before instruction execution)/read/longword |
| | | |

Execution-times break enabled (5 times)

On channel A, a user break occurs before the instruction at address H'00000500 is executed. On channel B, a user break occurs before the fifth instruction execution after the instruction at address H'00001000 has been executed four times.

6. Register specifications

BARA = H'00008404, BAMRA = H'00000FFF, BBRA = H'0054, BARB = H'00008010, BAMRB = H'0000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000400, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B independent mode

- Channel A
 Address: H'00008404, Address mask: H'00000FFF, ASID: H'80
 Bus cycle: CPU/instruction fetch (after instruction execution)/read (operand size is not included in the condition)
- Channel B

•

| Address: | H'00008010, Address mask: H'00000006, ASID: H'70 |
|------------|--|
| Data: | H'0000000, Data mask: H'00000000 |
| Bus cycle: | CPU/instruction fetch (before instruction execution)/read (operand size is not |
| | included in the condition) |

A user break occurs after an instruction with ASID = H'80 and address H'00008000 to H'00008FFE is executed or before instructions with ASID = H'70 and addresses H'00008010 to H'00008016 are executed.

Break Condition Specified for CPU Data Access Cycle

1. Register specifications

```
BARA = H'00123456, BAMRA = H'00000000, BBRA = H'0064, BARB = H'000ABCDE.
BAMRB = H'000000FF, BBRB = H'006A, BDRB = H'0000A512, BDMRB = H'00000000,
BRCR = H'00000080, BASRA = H'80, BASRB = H'70
```

Specified conditions: Channel A/channel B independent mode

- Channel A Address: H'00123456, Address mask: H'00000000, ASID: H'80 Bus cycle: CPU/data access/read (operand size is not included in the condition)
- Channel B •

Address: H'000ABCDE, Address mask: H'000000FF, ASID: H'70 Data. H'0000A512. Data mask: H'00000000 Bus cycle: CPU/data access/write/word

On channel A, a user break occurs with ASID = H'80 during longword read to address H'00123454, word read to address H'00123456, or byte read to address H'00123456. On channel B, a user break occurs with ASID = H'70 when word H'A512 is written in addresses H'000ABC00 to H'000ABCFE.

2. Register specifications:

BARA = H'01000000, BAMRA = H'00000000, BBRA = H'0066, BARB = H'0000F000. BAMRB = H'FFFF0000, BBRB = H'036A, BDRB = H'00004567, BDMRB = H'00000000, BRCR = H'00300080

Specified conditions: Channel A/channel B independent mode

Channel A

H'01000000, Address mask: H'00000000 Address: Bus cycle: CPU/data access/read/word No ASID check is included

• Channel B

> Y Address: H'0001F000, Address mask: H'FFFF0000 Data: H'00004567. Data mask: H'00000000 Bus cycle: CPU/data access/write/word No ASID check is included

On channel A, a user break occurs during word read to address H'01000000 in the memory space. On channel B, a user break occurs when word H'4567 is written in address H'0001F000 in Y memory space. X/Y-memory space is changed by a mode specification.

> www.DataSheet4U.com Rev. 5.0, 09/03, page 223 of 806

Break Condition Specified for DMAC Data Access Cycle

1. Register specifications:

BARA = H'00314156, BAMRA = H'00000000, BBRA = H'0094, BARB = H'00055555, BAMRB = H'00000000, BBRB = H'00A9, BDRB = H'00000078, BDMRB = H'0000000F, BRCR = H'00000080, BASRA = H'80, BASRB = H'70 www.DataSheet4U.com

Specified conditions: Channel A/channel B independent mode

Channel A
 Address: H'00314156, Address mask: H'00000000, ASID: H'80

 Bus cycle: DMAC/instruction fetch/read (operand size is not included in the condition)
 Channel B
 Address: H'00055555, Address mask: H'00000000, ASID: H'70

 Data: H'0000078, Data mask: H'0000000F
 Bus cycle: DMAC/data access/write/byte

On channel A, no user break occurs since an instruction fetch is not performed in DMAC cycles. On channel B, a user break occurs with ASID = H'70 when the DMAC writes byte $H'7^*$ in address H'00055555.

8.3.9 Notes

- 1. Only the CPU can read/write to UBC registers.
- 2. The UBC cannot monitor CPU and DMAC access in the same channel.
- 3. Notes on the specification of a sequential break are given below:
 - a. A condition match occurs when a channel B match occurs in a bus cycle after a channel A match occurs in another bus cycle in sequential break setting. Therefore, no condition match occurs if a bus cycle in which a channel A match and a channel B match occur simultaneously is set.
 - b. Since the CPU has a pipeline configuration, the pipeline determines the order of an instruction fetch cycle and a memory cycle. Therefore, when a channel condition matches in the order of bus cycles, a sequential condition is satisfied.
 - c. When the bus cycle condition for channel A is specified as a break before execution (PCBA = 0 in BRCR) and an instruction fetch cycle (in BBRA), the following point must be noted. A break is issued, and condition match flags in BRCR are set to 1, when the bus cycle conditions both for channels A and B match simultaneously.
- 4. The change of a UBC register value is executed in the MA (memory access) stage. Therefore, even if the break condition matches in the instruction fetch address following the instruction in which pre-execution break is specified as the break condition, no break occurs. In order to ascertain the timing of a UBC register is change, read the last register written to. Instructions after then are valid for the newly written register value.
- 5. Note the following when specifying an instruction in repeat execution, including a repeat instruction, as the break condition: When an instruction in a repeat loop is specified as the break condition,
 - a. A break is not issued during execution of a repeat loop with fewer than three instructions.
 - b. When an execution-times break is set, no instruction fetch from memory occurs during execution of a repeat loop with fewer than three instructions. Therefore, the value in the execution times register, BETR, is not decremented.
- 6. The branch instruction should not be executed as soon as PC trace registers BRSR and BRDR are read.
- 7. If a PC break and a TLB exception or error occur in the same instruction, the priority is as follows:
 - a. Break and instruction fetch exceptions: Instruction fetch exception occurs first.
 - b. Break before execution and operand exception: Break before execution occurs first.
 - c. Break after execution and operand exception: Operand exception occurs first.

Section 9 Power-Down Modes

9.1 Overview

In the power-down modes, all CPU and some on-chip peripheral module functions are halted. This lowers power consumption.

9.1.1 Power-Down Modes

The SH7729R has the following power-down modes and function:

- 1. Sleep mode
- 2. Standby mode
- 3. Module standby function (TMU, RTC, SCI, X/Y memory, UBC, DMAC, DAC, ADC, SCIF, and IrDA on-chip peripheral modules)
- 4. Hardware standby mode

Table 9.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

Table 9.1Power-Down Modes

| | State | | | | | | | | |
|-------------------------------|--|-------|-----------------------------------|----------------------|-------------------|----------------------------------|------|--------------------|---------------------------------------|
| Mode | Transition Conditions | CPG | CPU | CPU Reg- ister | On-Chip Memory | On-Chip Peripheral Modules | Pins | External Memory | Canceling Procedure |
| Sleep mode | Execute SLEEP instruction with STBY bit cleared to 0 in STBCR | Runs | Halts (Reg- ister: held) | Held | Held | Run | Held | Refresh | 1. Interrupt 2. Reset |
| Standby mode | Execute SLEEP instruction with STBY bit set to 1 in STBCR | Halts | Halts (Reg- ister: held) | Held | Held | Halt ^{*1} | Held | Self- refresh | 1. Interrupt 2. Reset |
| Module standby function | Set MSTP bit to 1 in STBCR | Runs | Runs or halts | Held | Held | Specified module halts | *2 | Refresh | 1. Clear MSTP bit to 0 2. Reset |
| Hardware standby mode | Drive CA pin low | Halts | Halts | Held | Held | Halt ^{*3} | Held | Self- refresh | Power-on reset |

Notes: 1. The RTC still runs if the START bit in RCR2 is set to 1 (see section 14, Realtime Clock (RTC)). The TMU still runs when output of the RTC is used as input to its counter (see section 13, Timer (TMU)).

 Depends on the on-chip peripheral module. TMU external pin: Held SCI external pin: Reset

3. The RTC still runs if the START bit in RCR2 is set to 1. The TMU does not run.

www.DataSheet4U.com

9.1.2 Pin Configuration

Table 9.2 lists the pins used for the power-down modes.

Table 9.2Pin Configuration

| Pin Name. DataSheet4 Symbol | | I/O | Description |
|-----------------------------|---------|-----|---|
| Processing state 1 | STATUS1 | 0 | Operating state of the processor. |
| Processing state 0 STATUS0 | | | HH: Reset, HL: Sleep mode, LH: Standby mode, LL: Normal operation |
| Wakeup from standby mode | WAKEUP | 0 | Active-low assertion after accepting wakeup interrupt in standby mode until returning to normal operation with WDT overflow |

Note: H: high level; L: low level

9.1.3 Register Configuration

Table 9.3 shows the control register configuration for the power-down modes.

Table 9.3Register Configuration

| Name | Abbreviation | R/W | Initial Value | Access Size | Address |
|----------------------------|--------------|-----|-------------------|-------------|------------|
| Standby control register | STBCR | R/W | H'00 [*] | Byte | H'FFFFFF82 |
| Standby control register 2 | STBCR2 | R/W | H'00 [*] | Byte | H'FFFFFF88 |

Note: * Initialized by a power-on reset. This value is not initialized by a manual reset; the current value is retained.

9.2 **Register Descriptions**

9.2.1 Standby Control Register (STBCR)

The standby control register (STBCR) is an 8-bit readable/writable register that sets the powerdown mode. STBCR is initialized to H'00 by a power-on reset. Always set bits 6–3 to 0 when writing to the STBCR register.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|------|---|---|--------|---|-------|-------|-------|
| | STBY | _ | — | STBXTL | _ | MSTP2 | MSTP1 | MSTP0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R/W | R | R/W | R/W | R/W |

Bit 7—Standby (STBY): Specifies transition to standby mode.

| Bit 7: STBY | Description | |
|-------------|--|----------|
| 0 | Executing SLEEP instruction puts chip into sleep mode value) | (Initial |
| 1 | Executing SLEEP instruction puts chip into standby mode | |

Bits 6, 5, and 3—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 4—Standby Crystal (STBXTL): Specifies halting or operating of the clock pulse generator in standby mode.

| Bit 4: STBXTL | Description |
|---------------|---|
| 0 | Clock pulse generator is halted in standby mode |
| 1 | Clock pulse generator is operates in standby mode |

Bit 2—Module Standby 2 (MSTP2): Specifies halting of the clock supply to the timer unit TMU (an on-chip peripheral module). When the MSTP2 bit is set to 1, the supply of the clock to the TMU is halted.

| Bit 2: MSTP2 | Description | |
|--------------|-------------------------------|-----------------|
| 0 | TMU runs | (Initial value) |
| 1 | Clock supply to TMU is halted | |

Bit 1—Module Standby 1 (**MSTP1**): Specifies halting of the clock supply to the realtime clock RTC (an on-chip peripheral module). When the MSTP1 bit is set to 1, the supply of the clock to the RTC is halted. When the clock halts, all RTC registers become inaccessible, but the counter keeps running.

| Bit 1: MSTP1 | Description | |
|--------------|-------------------------------|-----------------|
| 0 | RTC runs | (Initial value) |
| 1 | Clock supply to RTC is halted | |

Before switching the RTC to module standby, access at least one among the registers RTC, SCI, and TMU.

Bit 0—Module Standby 0 (MSTP0): Specifies halting of the clock supply to the serial communication interface SCI (an on-chip peripheral module). When the MSTP0 bit is set to 1, the supply of the clock to the SCI is halted.

| Bit 0: MSTP0 | Description | |
|--------------|-------------------------------|-----------------|
| 0 | SCI operates | (Initial value) |
| 1 | Clock supply to SCI is halted | |

9.2.2 Standby Control Register 2 (STBCR2)

The standby control register 2 (STBCR2) is a readable/writable 8-bit register that sets the powerdown mode. STBCR2 is initialized to H'00 by a power-on reset.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | MSTP9 | MDCHG | MSTP8 | MSTP7 | MSTP6 | MSTP5 | MSTP4 | MSTP3 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W |

Bit 7—Module Stop 9 (MSTP9): Specifies halting of the clock supply to the X/Y memory (an on-chip peripheral module). When the MSTP9 bit is set to 1, the supply of the clock to the memory is halted.

| Bit 7: MSTP9 | Description | |
|--------------|-----------------------------------|-----------------|
| 0 | X/Y memory runs | (Initial value) |
| 1 | Clock supply to X/Y memory halted | |

Bit 6—Pin MD5 to MD0 Control (MDCHG): Specifies whether or not pins MD5 to MD0 are changed in standby mode. When this bit is set to 1, the MD5 to MD0 pin values are latched when returning from standby mode by means of a reset or interrupt.

| Bit 6: MDCHG | Description | |
|--------------|---|-----------------|
| 0 | Pins MD5 to MD0 are not changed in standby mode | (Initial value) |
| 1 | Pins MD5 to MD0 are changed in standby mode | |

Bit 5— Module Stop 8 (MSTP8): Specifies halting of the clock supply to the user break controller UBC (an on-chip peripheral module). When the MSTP8 bit is set to 1, the supply of the clock to the UBC is halted.

| Bit 5: MSTP8 | Description | |
|--------------|-------------------------------|-----------------|
| 0 | UBC runs | (Initial value) |
| 1 | Clock supply to UBC is halted | |

Bit 4—Module Stop 7 (MSTP7): Specifies halting of the clock supply to the DMAC (an on-chip peripheral module). When the MSTP7 bit is set to 1, the supply of the clock to the DMAC is halted.

| Bit 4: MSTP7 | Description | |
|---------------|-----------------------------|-----------------|
| 0 | DMAC runs | (Initial value) |
| 1 www.DataShe | Clock supply to DMAC halted | |

Bit 3—Module Stop 6 (MSTP6): Specifies halting of the clock supply to the DAC (an on-chip peripheral module). When the MSTP6 bit is set to 1, the supply of the clock to the DAC is halted.

| Bit 3: MSTP6 | Description | |
|--------------|----------------------------|-----------------|
| 0 | DAC runs | (Initial value) |
| 1 | Clock supply to DAC halted | |

Bit 2—Module Stop 5 (MSTP5): Specifies halting of the clock supply to the ADC (an on-chip peripheral module). When the MSTP5 bit is set to 1, the supply of the clock to the ADC is halted and all registers are initialized.

| Bit 2: MSTP5 | Description | |
|--------------|--|-----------------|
| 0 | ADC runs | (Initial value) |
| 1 | Clock supply to ADC halted and all registers initialized | |

Bit 1—Module Stop 4 (MSTP4): Specifies halting of the clock supply to the SCI2 (SCIF) serial communication interface with FIFO (an on-chip peripheral module). When the MSTP1 bit is set to 1, the supply of the clock to SCI2 (SCIF) is halted.

| Bit 1: MSTP4 | Description | |
|--------------|------------------------------------|-----------------|
| 0 | SCI2 (SCIF) runs | (Initial value) |
| 1 | Clock supply to SCI2 (SCIF) halted | |

Bit 0—Module Stop 3 (MSTP3): Specifies halting of the clock supply to the SCI1 (IrDA) Infrared Data Association interface with FIFO (an on-chip peripheral module). When the MSTP1 bit is set to 1, the supply of the clock to SCI1 (IrDA) is halted.

| Bit 0: MSTP3 | Description | |
|--------------|-----------------------------------|-----------------|
| 0 | SCI1(IrDA) runs | (Initial value) |
| 1 | Clock supply to SCI1(IrDA) halted | |

9.3 Sleep Mode

9.3.1 Transition to Sleep Mode

Executing the SLEEP instruction when the STBY bit in STBCR is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the SLEEP instruction, the contents of its internal registers remain unchanged. The on-chip peripheral modules continue to run in sleep mode and the clock continues to be output to the CKIO and CKIO2 pins. In sleep mode, the STATUS1 pin is set high and the STATUS0 pin low.

DMAC transfers should not be performed in the sleep mode under conditions other than when the clock ratio of I ϕ (on-chip clock) to B ϕ (bus clock) is 1:1.

9.3.2 Canceling Sleep Mode

Sleep mode is canceled by an interrupt (NMI, IRQ, IRL, on-chip peripheral module, PINT) or reset. Interrupts are accepted in sleep mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR to the stack before executing the SLEEP instruction.

Canceling with an Interrupt: When an NMI, IRQ, IRL or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. A code indicating the interrupt source is set in the INTEVT and INTEVT2 registers.

Canceling with a Reset: Sleep mode is canceled by a power-on reset or a manual reset.

9.4 Standby Mode

9.4.1 Transition to Standby Mode

To enter standby mode, set the STBY bit to 1 in STBCR, then execute the SLEEP instruction. The chip switches from the program execution state to standby mode. In standby mode, power consumption is greatly reduced by halting not only the CPU, but the clock and on-chip peripheral modules as well. The clock output from the CKIO and CKIO2 pins also halts. CPU and cache register contents are held, but some on-chip peripheral modules are initialized. Table 9.4 lists the states of registers in standby mode.

| Module | Registers Initialized | Registers Retaining Data |
|-------------------------------|------------------------------|---------------------------------|
| Interrupt controller | _ | All registers |
| On-chip clock pulse generator | _ | All registers |
| User break controller (UBC) | — | All registers |
| Bus state controller (BSC) | _ | All registers |
| Timer unit (TMU) | TSTR register | Registers other than TSTR |
| Realtime clock (RTC) | _ | All registers |
| A/D converter (ADC) | All registers | — |
| D/A converter (DAC) | _ | All registers |

Table 9.4 Register States in Standby Mode

The procedure for moving to standby mode is as follows:

- Clear the TME bit in the WDT's timer control register (WTCSR) to 0 to stop the WDT. Set the WDT's timer counter (WTCNT) and the CKS2–CKS0 bits in the WTCSR register to appropriate values to secure the specified oscillation settling time.
- 2. After the STBY bit in the STBCR register is set to 1, a SLEEP instruction is executed.
- 3. Standby mode is entered and the clocks within the chip are halted. The STATUS1 pin output goes low and the STATUS0 pin output goes high.

www.DataSheet4U.com

9.4.2 Canceling Standby Mode

Standby mode is canceled by an interrupt (NMI, IRQ, IRL, PINT, or on-chip peripheral module) or a reset.

Canceling with an Interrupt: The on-chip WDT can be used for hot starts. When the chip detects an NMI, IRL, IRQ, PINT^{*1}, or on-chip peripheral module (except interval timer)^{*2} interrupt, the clock will be supplied to the entire chip and standby mode canceled after the time set in the WDT's timer control/status register has elapsed. The STATUS1 and STATUS0 pins both go low. Interrupt handling then begins and a code indicating the interrupt source is set in the INTEVT and INTEVT2 registers. After the branch to the interrupt handling routine, clear the STBY bit in the STBCR register. WTCNT stops automatically. If the STBY bit is not cleared, WTCNT continues operation and a transition is made to standby mode^{*3} when it reaches H'80. This function prevents the data from being destroyed due to a rise in voltage with an unstable power supply, etc. Interrupts are accepted in standby mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR to the stack before executing the SLEEP instruction. Immediately after an interrupt is detected, the phase of the CKIO pin clock output may be unstable, until the processor starts interrupt handling. (The canceling condition is that the IRL3–IRL0 level is higher than the mask level in the I3–I0 bits in the SR register.)

- Notes: 1. When the RTC is being used, standby mode can be canceled using IRL3–IRL0, IRQ4–IRQ0, or PINT0/1.
 - 2. Standby mode can be canceled with an RTC or TMU (only when running on the RTC clock) interrupt.
 - 3. This standby mode can be canceled only by a power-on reset.

Figure 9.1 Canceling Standby Mode with STBCR.STBY

www.DataSheet4U.com Rev. 5.0, 09/03, page 235 of 806

Canceling with a Reset: Standby mode is canceled by a reset (power-on or manual). Keep the $\overrightarrow{\text{RESET}}$ pin low until the clock oscillation settles. The internal clock will continue to be output to the CKIO and CKIO2 pins.

9.4.3 Clock Pause Function

In standby mode, the clock input from the EXTAL pin or CKIO pin can be halted and the frequency can be changed. This function is used as follows:

- 1. Enter standby mode using the appropriate procedures.
- 2. Once standby mode is entered and the clock stopped within the chip, the STATUS1 pin output is low and the STATUS0 pin output is high.
- 3. Once the STATUS1 pin goes low and the STATUS0 pin goes high, the input clock is stopped or the frequency is changed.
- 4. When the frequency is changed, an NMI, IRL, IRQ, PINT, or on-chip peripheral module (except interval timer) interrupt is input after the change. When the clock is stopped, the same interrupts are input after the clock is applied.
- 5. After the time set in the WDT has elapsed, the clock starts being applied internally within the chip, the STATUS1 and STATUS0 pins both go low, and operation resumes from interrupt exception handling.

9.5 Module Standby Function

9.5.1 Transition to Module Standby Function

Setting the standby control register MSTP9–MSTP0 bits to 1 halts the supply of clocks to the corresponding on-chip peripheral modules. This function can be used to reduce the power consumption in sleep mode. The module standby function holds the state prior to halting the external pins of the on-chip peripheral modules. TMU external pins hold their state prior to the halt. SCI external pins go to the reset state. With a few exceptions, all registers hold their values.

| Bit | Value | Description |
|-------|-------|---|
| MSTP9 | 0 | X/Y memory runs |
| | 1 | Supply of clock to X/Y memory halted |
| MSTP8 | 0 | UBC runs |
| | 1 | Supply of clock to UBC halted |
| MSTP7 | 0 | DMAC runs |
| | 1 | Supply of clock to DMAC halted |
| MSTP6 | 0 | DAC runs |
| | 1 | Supply of clock to DAC halted |
| MSTP5 | 0 | ADC runs |
| | 1 | Supply of clock to ADC halted, and all registers initialized |
| MSTP4 | 0 | SCIF runs |
| | 1 | Supply of clock to SCIF halted |
| MSTP3 | 0 | IrDA runs |
| | 1 | Supply of clock to IrDA halted |
| MSTP2 | 0 | TMU runs |
| | 1 | Supply of clock to TMU halted. Registers initialized*1 |
| MSTP1 | 0 | RTC runs |
| | 1 | Supply of clock to RTC halted. Register access prohibited*2*3 |
| MSTP0 | 0 | SCI runs |
| | 1 | Supply of clock to SCI halted |

Notes: 1. The registers initialized are the same as in standby mode (see table 9.4).

- 2. The counter runs.
- 3. Before putting the RTC into module standby status, first access one or more of the RTC, SCI, and TMU registers. The RTC may then be put into module standby status.

9.5.2 Clearing Module Standby Function

The module standby function can be cleared by clearing the MSTP9–MSTP0 bits to 0, or by a power-on reset or manual reset. www.DataSheet4U.com

9.7 Hardware Standby Mode

9.7.1 Transition to Hardware Standby Mode

Driving the CA pin low causes a transition to hardware standby mode. In hardware standby mode, all modules except those operating on an RTC clock are halted, as in the standby mode entered on execution of a SLEEP instruction ((software) standby mode).

Hardware standby mode differs from (software) standby mode as follows.

- 1. Interrupts and manual resets are not accepted.
- 2. The TMU does not operate.

Operation when a low-level signal is input at the CA pin depends on the CPG state, as follows.

1. In standby mode

The clock remains stopped and the chip enters the hardware standby state. Acceptance of interrupts and manual resets is disabled, TCLK output is fixed low, and the TMU halts.

- During WDT operation when standby mode is canceled by an interrupt The chip enters hardware standby mode after standby mode is canceled and the CPU resumes operation.
- 3. In sleep mode

The chip enters hardware standby mode after sleep mode is canceled and the CPU resumes operation.

Hold the CA pin low in hardware standby mode.

9.7.2 Canceling Hardware Standby Mode

Hardware standby mode can only be canceled by a power-on reset.

When the CA pin is driven high while the **RESETP** pin is low, clock oscillation is started. Hold the **RESETP** pin low until clock oscillation stabilizes. When the **RESETP** pin is driven high, the CPU begins power-on reset processing.

Operation is not guaranteed in the event of an interrupt or manual reset.

www.DataSheet4U.com Rev. 5.0, 09/03, page 245 of 806

9.7.3 Hardware Standby Mode Timing

Figures 9.10 and 9.11 show examples of pin timing in hardware standby mode.

The CA pin is sampled using EXTAL2 (32.768 kHz), and a hardware standby request is only recognized when the pin is low for two consecutive clock cycles.

www.DataSheet4U.com

The CA pin must be held low while the chip is in hardware standby mode.

Clock oscillation starts when the CA pin is driven high after the **RESETP** pin is driven low.

Section 10 On-Chip Oscillation Circuits

10.1 Overview

The clock pulse generator (CPG) supplies all clocks to the processor and controls the power-down modes. The watchdog timer (WDT) is a single-channel timer that counts the clock settling time and is used when clearing standby mode and temporary standbys, such as frequency changes. It can also be used as an ordinary watchdog timer or interval timer.

10.1.1 Features

The CPG has the following features:

- Four clock modes: Selection of four clock modes for different frequency ranges, power consumption, direct crystal input, and external clock input.
- Three clocks generated independently: An internal clock for the CPU, cache, and TLB (Ιφ); a
 peripheral clock (Pφ) for the on-chip peripheral modules; and a bus clock (CKIO) for the
 external bus interface.
- Frequency change function: Internal and peripheral clock frequencies can be changed independently using the PLL circuit and divider circuit within the CPG. Frequencies are changed by software using frequency control register (FRQCR) settings.
- Power-down mode control: The clock can be stopped for sleep mode and standby mode and specific modules can be stopped using the module standby function.

The WDT has the following features:

- Can be used to ensure the clock settling time: Use the WDT to cancel standby mode and the temporary standbys which occur when the clock frequency is changed.
- Can switch between watchdog timer mode and interval timer mode.
- Generates internal resets in watchdog timer mode: Internal resets occur after counter overflow. Selection of power-on reset or manual reset.
- Generates interrupts in interval timer mode: Internal timer interrupts occur after counter overflow.
- Selection of eight counter input clocks. Eight clocks (×1 to ×1/4096) can be obtained by dividing the peripheral clock.

www.DataSheet4U.com Rev. 5.0, 09/03, page 249 of 806

10.2 Overview of CPG

10.2.1 CPG Block Diagram

A block diagram of the on-chip clock pulse generator is shown in figure 10.1.

Figure 10.1 Block Diagram of Clock Pulse Generator

www.DataSheet4U.com

The clock pulse generator blocks function as follows:

- 1. PLL Circuit 1: PLL circuit 1 doubles, triples, quadruples, sextuples, or leaves unchanged the input clock frequency from the CKIO pin. The multiplication rate is set by the frequency control register. When this is done, the phase of the leading edge of the internal clock is controlled so that it will agree with the phase of the leading edge of the CKIO pin.
- 2. PLL Circuit 2: PLL circuit 2 leaves unchanged or quadruples the frequency of the crystal oscillator or the input clock frequency from the EXTAL pin. The multiplication ratio is fixed by the clock operation mode. The clock operation mode is set by pins MD0, MD1, and MD2. See table 10.3 for more information on clock operation modes.
- 3. Crystal Oscillator: This oscillator is used when a crystal oscillator element is connected to the XTAL and EXTAL pins. It operates according to the clock operating mode setting.
- 4. Divider 1: Divider 1 generates a clock at the operating frequency used by the internal clock. The operating frequency can be 1, 1/2, 1/3, 1/4, or 1/6 times the output frequency of PLL circuit 1, as long as it is not lower than the CKIO pin clock frequency. The division ratio is set in the frequency control register.
- 5. Divider 2: Divider 2 generates a clock at the operating frequency used by the peripheral clock. The operating frequency can be 1, 1/2, 1/3, 1/4, or 1/6 times the output frequency of PLL circuit 1 or the CKIO pin clock frequency, as long as it is not higher than the CKIO pin clock frequency. The division ratio is set in the frequency control register.
- 6. Clock Frequency Control Circuit: The clock frequency control circuit controls the clock frequency using the MD pins and the frequency control register.
- 7. Standby Control Circuit: The standby control circuit controls the state of the clock pulse generator and other modules during clock switching and sleep/standby modes.
- Frequency Control Register: The frequency control register has control bits assigned for the following functions: clock output/non-output from the CKIO pin, on/off control of PLL circuit 1, PLL standby, the frequency multiplication ratio of PLL 1, and the frequency division ratio of the internal clock and the peripheral clock.
- 9. Standby Control Register: The standby control register has bits for controlling the power-down modes. See section 9, Power-Down Modes, for more information.

10.2.2 CPG Pin Configuration

Table 10.1 lists the CPG pins and their functions.

| Table 10.1 CFG Fills and Functions | Table 10.1 | CPG Pins and Functions |
|------------------------------------|-------------------|-------------------------------|
|------------------------------------|-------------------|-------------------------------|

| Pin Name | Symbol | I/O | Description |
|---------------------------|--------|-----|---|
| Mode control | MD0 | Ι | Set the clock operating mode |
| pins | MD1 | Ι | |
| | MD2 | Ι | |
| Crystal I/O pins | XTAL | 0 | Connects a crystal oscillator |
| (clock input pins) | EXTAL | I | Connects a crystal oscillator. Also used to input an external clock |
| Clock I/O pin | CKIO | I/O | Inputs or outputs an external clock. Level can be fixed during output |
| Capacitor connection pins | CAP1 | I | Connects capacitor for PLL circuit 1 operation (recommended value 470 pF) |
| for PLL | CAP2 | I | Connects capacitor for PLL circuit 2 operation (recommended value 470 pF) |

10.2.3 CPG Register Configuration

Table 10.2 shows the CPG register configuration.

Table 10.2CPG Register

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------------|--------------|-----|---------------|------------|-------------|
| Frequency control register | FRQCR | R/W | H'0102 | H'FFFFFF80 | 16 |

10.3 Clock Operating Modes

Table 10.3 shows the relationship between the mode control pin (MD2–MD0) combinations and the clock operating modes. Table 10.4 shows the usable frequency ranges in the clock operating modes.

| | Pi | in Val | ues | Cloci | < I/O | PLL2 PLL1 | | Divider 1 | Divider 2 | СКІО |

| _ | Value above | es exce e | ept | Reserved | (Setting | prohibited |) | | | |

Table 10.3 Clock Operating Modes

Mode 0: An external clock is input from the EXTAL pin and undergoes waveform shaping by PLL circuit 2 before being supplied inside the chip. PLL circuit 1 is constantly on, and there are no frequency range restrictions compared to mode 3. An input clock frequency of 25 MHz to 66.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

As PLL circuit 1 compensates for fluctuations in the CKIO pin load, this mode is suitable for connection of synchronous DRAM.

Mode 1: An external clock is input from the EXTAL pin and its frequency is multiplied by 4 by PLL circuit 2 before being supplied inside the chip, allowing a low-frequency external clock to be used. An input clock frequency of 6.25 MHz to 16.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

As PLL circuit 1 compensates for fluctuations in the CKIO pin load, this mode is suitable for connection of synchronous DRAM.

www.DataSheet4U.com Rev. 5.0, 09/03, page 253 of 806

Mode 2: The on-chip crystal oscillator operates, with the oscillation frequency being multiplied by 4 by PLL circuit 2 before being supplied inside the chip, allowing a low crystal frequency to be used. A crystal oscillation frequency of 6.25 MHz to 16.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

As PLL circuit 1 compensates for fluctuations in the CKIO pin load, this mode is suitable for connection of synchronous DRAM.

Mode 7: In this mode, the CKIO pin is an input, an external clock is input to this pin, and undergoes waveform shaping, and also frequency multiplication according to the setting, by PLL circuit 1 before being supplied to the chip. In modes 0 to 4, the system clock is generated from the output of the chip's CKIO pin. Consequently, if a large number of ICs are operating on the clock cycle, the CKIO pin load will be large. This mode, however, assumes a comparatively large-scale system. If a large number of ICs are operating on the clock cycle, a clock generator with a number of low-skew clock outputs can be provided, so that the ICs can operate synchronously by distributing the clocks to each one.

As PLL circuit 1 compensates for fluctuations in the CKIO pin load, this mode is suitable for connection of synchronous DRAM.

| Clock Mode | FRQCR | PLL1 | PLL2 | Clock Rate [*] (I:B:P) | Input Frequency Range | CKIO Frequency Range |
|---------------|--------|----------|----------|------------------------------------|--------------------------|-------------------------|
| 0 | H'0100 | ON (× 1) | ON (× 1) | 1:1:1 | 25 MHz to 33.34 MHz | 25 MHz to 33.34 MHz |
| | H'0101 | ON (× 1) | ON (× 1) | 1:1:1/2 | 25 MHz to 66.67 MHz | 25 MHz to 66.67 MHz |
| | H'0102 | ON (× 1) | ON (× 1) | 1:1:1/4 | 25 MHz to 66.67 MHz | 25 MHz to 66.67 MHz |
| | H'0111 | ON (× 2) | ON (× 1) | 2:1:1 | 25 MHz to 33.34 MHz | 25 MHz to 33.34 MHz |
| | H'0112 | ON (× 2) | ON (× 1) | 2:1:1/2 | 25 MHz to 66.67 MHz | 25 MHz to 66.67 MHz |
| | H'0115 | ON (× 2) | ON (× 1) | 1:1:1 | 25 MHz to 33.34 MHz | 25 MHz to 33.34 MHz |
| | H'0116 | ON (× 2) | ON (× 1) | 1:1:1/2 | 25 MHz to 66.67 MHz | 25 MHz to 66.67 MHz |

| | H'E101 | ON (× 3) | OFF | 1:1:1/2 | 25 MHz to 66.67 MHz | 25 MHz to 66.67 MHz |
| | H'A111 | ON (× 6) | OFF | 6:1:1 | 25 MHz to 33.34 MHz | 25 MHz to 33.34 MHz |

Note: * Taking input clock as 1.

Cautions:

- 1. The input to divider 1 becomes the output of PLL circuit 1 when PLL circuit 1 is on.
- 2. The input of divider 2 becomes the output of PLL circuit 1.
- 3. The frequency of the internal clock $(I\phi)$ becomes:
 - The product of the frequency of the CKIO pin, the frequency multiplication ratio of PLL circuit 1, and the division ratio of divider 1 when PLL circuit 1 is on.
 - Do not set the internal clock frequency lower than the CKIO pin frequency.

www.DataSheet4U.com

10.4 Register Descriptions

10.4.1 Frequency Control Register (FRQCR)

The frequency control register (FRQCR) is a 16-bit readable/writable register used to specify the frequency multiplication ratio of PLL circuit 1, and the frequency division ratio of the internal clock and the peripheral clock.

Only word access can be used on the FRQCR register. FRQCR is initialized to H'0102 by a power-on reset trigged by the $\overrightarrow{\text{RESETP}}$ pin, but retains its value in a manual reset and in standby mode.

FRQCR:

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|------|------|------|------|------|------|------|------|
| | STC2 | IFC2 | PFC2 | — | _ | _ | — | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R/W | R/W | R/W | R | R | R | R | R |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | STC1 | STC0 | IFC1 | IFC0 | PFC1 | PFC0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| R/W: | R | R | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15, 5, and 4—Frequency Multiplication Ratio (STC2, STC1, STC0): These bits specify the frequency multiplication ratio of PLL circuit 1.

| Bit 15: STC2 | Bit 5: STC1 | Bit 4: STC0 | Description | |
|-----------------|-------------|-------------|-------------------------------|-----------------|
| 0 | 0 | 0 | × 1 | (Initial value) |
| 0 | 0 | 1 | ×2 | |
| 1 | 0 | 0 | ×3 | |
| 0 | 1 | 0 | × 4 | |
| 1 | 0 | 1 | ×6 | |
| Values except a | above | | Reserved (Setting prohibited) | |

Bits 14, 3, and 2—Internal Clock Frequency Division Ratio (IFC2, IFC1, IFC0): These bits specify the frequency division ratio of the internal clock with respect to the output frequency of PLL circuit 1.

| Bit 14: IFC2 | Bit 3: IFC1 | Bit 2: IFC0 | Description | |
|-----------------|--------------|-------------|-------------------------------|-----------------|
| 0 | 0 | 0 | ×1 | (Initial value) |
| 0 www.Da | aSheel40.com | 1 | × 1/2 | |
| 1 | 0 | 0 | × 1/3 | |
| 0 | 1 | 0 | × 1/4 | |
| Values except a | above | | Reserved (Setting prohibited) | |

Note: Do not set the internal clock frequency lower than the CKIO pin frequency.

Bits 13, 1, and 0—Peripheral Clock Frequency Division Ratio (PFC2, PFC1, PFC0): These bits specify the division ratio of the peripheral clock frequency with respect to the frequency of the output frequency of PLL circuit 1 or the frequency of the CKIO pin.

| Bit 13: PFC2 | Bit 1: PFC1 | Bit 0: PFC0 | Description |
|-----------------|-------------|-------------|-------------------------------|
| 0 | 0 | 0 | × 1 |
| 0 | 0 | 1 | × 1/2 |
| 1 | 0 | 0 | × 1/3 |
| 0 | 1 | 0 | × 1/4 (Initial value) |
| 1 | 0 | 1 | × 1/6 |
| Values except a | bove | | Reserved (Setting prohibited) |

Note: Do not set the peripheral clock frequency higher than the CKIO pin frequency.

Bits 12 to 9, 7, and 6—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 8—Reserved: This bit is always read as 1. The write value should always be 1.

10.5 Changing the Frequency

The frequency of the internal clock and peripheral clock can be changed either by changing the multiplication ratio of PLL circuit 1 or by changing the division ratios of dividers 1 and 2. All of these are controlled by software through the frequency control register. The methods are described below.

www.DataSheet4U.com

10.5.1 Changing the Multiplication Rate

A PLL settling time is required when the multiplication rate of PLL circuit 1 is changed. The onchip WDT counts the settling time.

- 1. In the initial state, the multiplication rate of PLL circuit 1 is 1.
- Set a value that will become the specified oscillation settling time in the WDT and stop the WDT. The following must be set: WTCSR register TME bit = 0: WDT stops WTCSR register CKS2–CKS0 bits: Division ratio of WDT count clock WTCNT counter: Initial counter value
- 3. Set the desired value in the STC2, STC1, and STC0 bits. The division ratio can also be set in the IFC2–IFC0 bits and PFC2–PFC0 bits.
- 4. The processor pauses internally and the WDT starts incrementing. In clock modes 0–2 and 7, the internal and peripheral clocks both stop (except for the peripheral clock supplied to the WDT).
- 5. Supply of the clock that has been set begins at WDT count overflow, and the processor begins operating again. The WDT stops after it overflows.

10.5.2 Changing the Division Ratio

The WDT will not count unless the multiplication ratio is changed simultaneously.

- 1. In the initial state, IFC2-IFC0 = 000 and PFC2-PFC0 = 010.
- 2. Set the IFC2, IFC1, IFC0, PFC2, PFC1, and PFC0 bits to the new division ratio. The values that can be set are limited by the clock mode and the multiplication ratio of PLL circuit 1. Note that if the wrong value is set, the processor will malfunction.
- 3. The clock is immediately supplied at the new division ratio.

10.5.3 Notes on Changing the Frequency

If the following three conditions are all met, FRQCR should not be changed when a transfer using the DMAC is in progress.

• Bits IFC2 to IFC0 are changed.

www.DataSheet4U.com Rev. 5.0, 09/03, page 259 of 806

- Bits STC2 to STC0 are not changed.
- The clock ratio is other than $I\phi:B\phi = 1:1$.

10.6 Overview of WDT

10.6.1 Block Diagram of WDT

Figure 10.2 shows a block diagram of the WDT.

Figure 10.2 Block Diagram of WDT

10.6.2 Register Configuration

The WDT has two registers that select the clock, switch the timer mode, and perform other functions. Table 10.5 shows the WDT registers.

| Name | Abbreviation | R/W | Access Size | Initial Value | Address |
|--|--------------|------|----------------------------------|---------------|------------|
| Watchdog timer counter | WTCNT | R/W* | R: byte; W: word [*] | H'00 | H'FFFFFF84 |
| Watchdog timer control/status register U.co | WTCSR | R/W* | R: byte; W: word [*] | H'00 | H'FFFFF86 |

Table 10.5Register Configuration

Note: * Write with word access. Write with H'5A and H'A5, respectively, in the upper byte. Byte or longword writes are not possible. Read with byte access.

10.7 WDT Registers

10.7.1 Watchdog Timer Counter (WTCNT)

The watchdog timer counter (WTCNT) is an 8-bit readable/writable counter that increments on the selected clock. WTCNT differs from other registers in that it is more difficult to write to. See section 10.7.3, Notes on Register Access, for details. When an overflow occurs, it generates a reset in watchdog timer mode and an interrupt in interval time mode. Its address is H'FFFFFF84. The WTCNT counter is initialized to H'00 only by a power-on reset through the RESETP pin. Use word access to write to the WTCNT counter, with H'5A in the upper byte. Use byte access to read WTCNT.

10.7.2 Watchdog Timer Control/Status Register (WTCSR)

The watchdog timer control/status register (WTCSR) is an 8-bit readable/writable register composed of bits to select the clock used for the count, bits to select the timer mode, and overflow flags. WTCSR differs from other registers in that it is more difficult to write to. See section 10.7.3, Notes on Register Access, for details. Its address is H'FFFFF86. The WTCSR register is initialized to H'00 only by a power-on reset through the RESETP pin. When a WDT overflow causes an internal reset, WTCSR retains its value. When used to count the clock settling time for canceling a standby, it retains its value after counter overflow. Use word access to write to the WTCSR counter, with H'A5 in the upper byte. Use byte access to read WTCSR.

Note: The method of writing data to this register differs from that for ordinary registers in order to ensure that data is not overwritten mistakenly. Refer to section 10.7.3, Notes on Register Access, for details.

www.DataSheet4U.com Rev. 5.0, 09/03, page 261 of 806

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-------|------|------|------|------|------|------|
| | TME | WT/IT | RSTS | WOVF | IOVF | CKS2 | CKS1 | CKS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bit 7—Timer Enable (TME): Starts and stops timer operation. Clear this bit to 0 when using the WDT in standby mode or when changing the clock frequency.

| Bit 7: TME | Description | |
|------------|--|-----------------|
| 0 | Timer disabled: Count-up stops and WTCNT value is retained | |
| | | (Initial value) |
| 1 | Timer enabled | |

Bit 6—Timer Mode Select (WT/IT): Selects whether to use the WDT as a watchdog timer or an interval timer.

| Bit 6: | WT/IT Description | |
|--------|---|----------------------------|
| 0 | Used as interval timer | (Initial value) |
| 1 | Used as watchdog timer | |
| Note: | If WT/IT is modified when the WDT is running, the up-count may no | ot be performed correctly. |

Bit 5—Reset Select (RSTS): Selects the type of reset when WTCNT overflows in watchdog timer mode. In interval timer mode, this setting is ignored.

| Bit 5: RSTS | Description | |
|-------------|----------------|-----------------|
| 0 | Power-on reset | (Initial value) |
| 1 | Manual reset | |
| Note: RESET | DUT is output. | |

Bit 4—Watchdog Timer Overflow (WOVF): Indicates that the WTCNT has overflowed in watchdog timer mode. This bit is not set in interval timer mode.

| Bit 4: WOVF | Description | |
|-------------|---|-----------------|
| 0 | No overflow | (Initial value) |
| 1 | WTCNT has overflowed in watchdog timer mode | |

Bit 3—Interval Timer Overflow (IOVF): Indicates that WTCNT has overflowed in interval timer mode. This bit is not set in watchdog timer mode.

www.DataSheet4U.com

| Bit 3: IOVF | Description | |
|-------------|---|-----------------|
| 0 | No overflow | (Initial value) |
| 1 | WTCNT has overflowed in interval timer mode | |

Bits 2 to 0—Clock Select 2 to 0 (CKS2 to CKS0): These bits select the clock to be used for the WTCNT count from the eight types obtainable by dividing the peripheral clock. The overflow period in the table is the value when the peripheral clock ($P\phi$) is 15 MHz.

| Bit 2: CKS2 | Bit 1: CKS1 | Bit 0: CKS0 | Clock Division Ratio | Overflow Period (when Pథ = 15 MHz) |
|-------------|-------------|-------------|----------------------|---------------------------------------|
| 0 | 0 | 0 | 1 (Initial value) | 17 μs |
| | | 1 | 1/4 | 68 µs |
| | 1 | 0 | 1/16 | 273 μs |
| | | 1 | 1/32 | 546 μs |
| 1 | 0 | 0 | 1/64 | 1.09 ms |
| | | 1 | 1/256 | 4.36 ms |
| | 1 | 0 | 1/1024 | 17.48 ms |
| | | 1 | 1/4096 | 69.91 ms |

Note: If bits CKS2–CKS0 are modified when the WDT is running, the up-count may not be performed correctly. Ensure that these bits are modified only when the WDT is not running.

10.7.3 Notes on Register Access

The watchdog timer counter (WTCNT) and watchdog timer control/status register (WTCSR) are more difficult to write to than other registers. The procedure for writing to these registers is given below.

Writing to WTCNT and WTCSR: These registers must be written to using a word transfer instruction. They cannot be written to with a byte or longword transfer instruction. When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in figure 10.3. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

www.DataSheet4U.com Rev. 5.0, 09/03, page 263 of 806

10.8 Using the WDT

10.8.1 Canceling Standby

The WDT can be used to cancel standby mode with an NMI or other interrupt. The procedure is described below. (The WDT does not run when a reset is used for canceling, so keep the RESET pin low until the clock stabilizes.)

- 1. Before transitioning to standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
- Set the type of count clock used in the CKS2–CKS0 bits in WTCSR and the initial values for the counter in the WTCNT counter. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
- 3. Switch to standby mode by executing a SLEEP instruction to stop the clock.
- 4. The WDT starts counting by detecting the edge change of the NMI signal or detecting interrupts.
- 5. When the WDT count overflows, the CPG starts supplying the clock and the processor resumes operation. The WOVF flag in WTCSR is not set when this happens.
- 6. Since the WDT continues counting from H'00, set the STBY bit in the STBCR register to 0 in the interrupt handling routine and this will stop the WDT. When the STBY bit remains at 1, the SH7729R again enters standby mode when the WDT has counted up to H'80. This standby mode can be canceled by a power-on reset

www.DataSheet4U.com

10.8.2 Changing the Frequency

To change the frequency used by the PLL, use the WDT. When changing the frequency only by switching the divider, do not use the WDT.

- 1. Before changing the frequency, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
- Set the type of count clock used in the CKS2–CKS0 bits of WTCSR and the initial values for the counter in the WTCNT counter. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
- 3. When the frequency control register (FRQCR) is written to, the clock stops and the processor enters standby mode temporarily. The WDT starts counting.
- 4. When the WDT count overflows, the CPG resumes supplying the clock and the processor resumes operation. The WOVF flag in WTCSR is not set when this happens.
- 5. The counter stops at a value of H'00 or H'01. The stop value depends on the clock ratio. If the following three conditions are all met, FRQCR should not be changed when a transfer using the DMAC is in progress.
 - Bits IFC2 to IFC0 are changed.
 - Bits STC2 to STC0 are not changed.
 - The clock ratio is other than $I\phi:B\phi = 1:1$.

10.8.3 Using Watchdog Timer Mode

- 1. Set the WT/IT bit in the WTCSR register to 1, set the reset type in the RSTS bit, set the type of count clock in the CKS2–CKS0 bits, and set the initial value of the counter in the WTCNT counter.
- 2. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
- 3. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
- 4. When the counter overflows, the WDT sets the WOVF flag in WTCSR to 1 and generates the type of reset specified by the RSTS bit. The counter then resumes counting. When a reset is generated, a low level is output at the RESETOUT pin, and a high level at the STATUS0 and STATUS1 pins. The output period is approximately 1 count clock cycle in the case of a power-on reset, and approximately 5 peripheral clock cycles in the case of a manual reset.

10.8.4 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

www.DataSheet4U.com Rev. 5.0, 09/03, page 265 of 806

- 1. Clear the WT/IT bit in the WTCSR register to 0, set the type of count clock in the CKS2–CKS0 bits, and set the initial value of the counter in the WTCNT counter.
- 2. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
- 3. When the counter overflows, the WDT sets the IOVF flag in WTCSR to 1 and an interval timer interrupt request is sent to the INTC. The counter then resumes counting.

10.9 Notes on Board Design

When Using an External Crystal Resonator: Place the crystal resonator, capacitors CL1 and CL2, and damping resistor R close to the EXTAL and XTAL pins. To prevent induction from interfering with correct oscillation, use a common grounding point for the capacitors connected to the resonator, and do not locate a wiring pattern near these components.

Figure 10.4 Points for Attention when Using Crystal Resonator

Decoupling Capacitors: Insert a laminated ceramic capacitor of 0.01 to 0.1 μ F as a passive capacitor for each V_{SS}/V_{CC} pair. Mount the passive capacitors close to the SH7729R power supply pins, and use components with a frequency characteristic suitable for the chip's operating frequency, as well as a suitable capacitance value.

Digital system V_{SS}/V_{CC} pairs: 19-21, 27-29, 33-35, 45-47, 57-59, 69-71, 79-81, 83-85, 95-97, 109-111, 132-134, 153-154, 161-163, 173-175, 181-183, 205-208

On-chip oscillator V_{SS}/V_{CC} pairs: 3-6, 145-147, 148-150

When Using a PLL Oscillator Circuit: Keep the wiring from the PLL V_{CC} and V_{SS} connection pattern to the power supply pins short, and make the pattern width large, to minipate sheet 4U.com

Rev. 5.0, 09/03, page 266 of 806

inductance component. Ground the oscillation stabilization capacitors C1 and C2 to V_{SS} (PLL1) and V_{SS} (PLL2), respectively. Place C1 and C2 close to the CAP1 and CAP2 pins and do not locate a wiring pattern in the vicinity. In clock mode 7, connect the EXTAL pin to V_{CC} or V_{SS} and leave the XTAL pin open.

Section 11 Bus State Controller (BSC)

11.1 Overview

The bus state controller (BSC) divides physical address space and output control signals for various types of memory and bus interface specifications. BSC functions enable the chip to link directly with synchronous DRAM, SRAM, ROM, and other memory storage devices without an external circuit. The BSC also allows direct connection to PCMCIA interfaces, simplifying system design and allowing high-speed data transfers in a compact system.

11.1.1 Features

The BSC has the following features:

- Physical address space is divided into six areas
 - A maximum 64 Mbytes for each of the six areas, 0, 2–6
 - Area bus width can be selected by register (area 0 is set by external pin)
 - Wait states can be inserted using the \overline{WAIT} pin
 - Wait state insertion can be controlled through software. Register settings can be used to specify the insertion of 1–10 cycles independently for each area (1–38 cycles for areas 5 and 6 and the PCMCIA interface only)
 - The type of memory connected can be specified for each area, and control signals are output for direct memory connection
 - Wait cycles are automatically inserted to avoid data bus conflict for continuous memory accesses to different areas or writes directly following reads in the same area
- Direct interface to synchronous DRAM
 - Multiplexes row/column addresses according to synchronous DRAM capacity
 - Supports burst operation
 - Supports bank active mode
 - Has both auto-refresh and self-refresh functions
 - Controls timing of synchronous DRAM direct-connection control signals according to register setting
- Burst ROM interface
 - Insertion of wait states controllable through software
 - Register setting control of burst transfers
- PCMCIA direct-connection interface
 - Insertion of wait states controllable through software
 - Bus sizing function for I/O bus width (only in little-endian mode)

www.DataSheet4U.com Rev. 5.0, 09/03, page 269 of 806

- Short refresh cycle control
 - The overflow interrupt function of the refresh counter enables the refresh function immediately after a self-refresh operation using low power-consumption DRAM
- The refresh counter can be used as an interval timer
 - Outputs an interrupt request signal using the compare-match function
 - Outputs an interrupt request signal when the refresh counter overflows
- Automatically disables the output of clock signals to anywhere but the refresh counter, except during execution of external bus cycles

11.1.2 Block Diagram

Figure 11.1 Block Diagram of Bus State Controller

11.1.3 Pin Configuration

Table 11.1 shows the BSC pin configuration.

Table 11.1 BSC Pins

| Pin Name | Signal | I/O | Description |
|-----------------------------|-----------------------|-----|--|
| Address bus | A25–A0 | 0 | Address output |
| Data bus | D15–D0 | I/O | Data I/O |
| | D31–D16 | I/O | Data I/O when using 32-bit bus width |
| Bus cycle start | BS | 0 | Shows start of bus cycle. During burst transfers, asserted every data cycle. |
| Chip select 0, 2-4 | CS0, CS2–CS4 | 0 | Chip select signals to indicate area being accessed. |
| Chip select 5, 6 | CS5/CE1A, CS6/CE1B | 0 | Chip select signals to indicate area being accessed. $\overline{CS5}/\overline{CE1A}$ and $\overline{CS6}/\overline{CE1B}$ can also be used as $\overline{CE1A}$ and $\overline{CE1B}$ of PCMCIA. |
| PCMCIA card select | CE2A, CE2B | 0 | CE2A and CE2B signals when PCMCIA is used |
| Read/write | RD/WR | 0 | Data bus direction indication signal. PCMCIA write indication signal. |
| Row address strobe 3L | RAS3L | 0 | When synchronous DRAM is used in area 3, RAS3L for lower 32-Mbyte address and 64-Mbyte address. |
| Row address strobe 3U | RAS3U | 0 | When synchronous DRAM is used in area 3, RAS3U for upper 32-Mbyte address. |
| Column address strobe | CASL | 0 | When synchronous DRAM is used, CASL signal for lower 32-Mbyte address and 64-Mbyte address. |
| Column address strobe LH | CASU | 0 | When synchronous DRAM is used, CASU signal for upper 32-Mbyte address. |
| Data enable 0 | WE0/DQMLL | 0 | When memory other than synchronous DRAM is used, D7–D0 write strobe signal. When synchronous DRAM is used, selects D7–D0. |
| Data enable 1 | WE1/DQMLU/ WE | 0 | When memory other than synchronous DRAM and PCMCIA is used, D15–D8 write strobe signal. When synchronous DRAM is used, selects D15– D8. When PCMCIA is used, strobe signal indicating write cycle. |
| Data enable 2 | WE2/DQMUL/ ICIORD | 0 | When memory other than synchronous DRAM and PCMCIA is used, D23–D16 write strobe signal. When synchronous DRAM is used, selects D23– D16. When PCMCIA is used, strobe signal indicating I/O read. |

| Pin Name | Signal | I/O | Description |
|-------------------------------|----------------------|-----|--|
| Data enable 3 | WE3/DQMUU/ ICIOWR | 0 | When memory other than synchronous DRAM and PCMCIA is used, D31–D24 write strobe signal. When synchronous DRAM is used, selects D31– D24. When PCMCIA is used, strobe signal indicating I/O write. |
| Read www.DataShee | etRDcom | 0 | Strobe signal indicating read cycle |
| Wait | WAIT | | Wait state request signal |
| Clock enable | CKE | 0 | Clock enable control signal for synchronous DRAM |
| IOIS16 | IOIS16 | I | Signal indicating PCMCIA 16-bit I/O. Valid only in little-endian mode. |
| Bus release request | BREQ | I | Bus release request signal |
| Bus release acknowledgment | BACK | 0 | Bus release acknowledge signal |
| Mask ROM chip select | MCS[0]-MCS[7] | 0 | Chip select signal for mask ROM connected to area 0 or 2. |

11.1.4 Register Configuration

The BSC has 21 registers (table 11.2). Synchronous DRAM also has a built-in synchronous DRAM mode register. These registers control direct connection interfaces to memory, wait states, refreshes, and PCMCIA devices.

Table 11.2 BSC Registers

Notes: For details, see section 11.2.7, Synchronous DRAM Mode Register (SDMR).

* Initialized by a power-on reset.

11.1.5 Area Overview

Space Allocation: In the architecture of the SH7729R, both logical spaces and physical spaces have 32-bit address spaces. The logical space is divided into five areas by the value of the upper bits of the address. The physical space is divided into eight areas.

Logical space can be allocated to physical space using a memory management unit (MMU). For details, refer to section 3, Memory Management Unit (MMU), which describes area allocation for physical space.

As shown in table 11.3, the SH7729R can be connected directly to six memory/PCMCIA interface areas, and it outputs chip select signals ($\overline{CS0}$, $\overline{CS2}$ – $\overline{CS6}$, $\overline{CE2A}$, $\overline{CE2B}$) for each of them. $\overline{CS0}$ is asserted during area 0 access; $\overline{CS6}$ is asserted during area 6 access. When PCMCIA interface is selected in area 5 or 6, in addition to $\overline{CS5}/\overline{CS6}$, $\overline{CE2A}/\overline{CE2B}$ are asserted for the corresponding bytes accessed.

Figure 11.2 Correspondence between Logical Address Space and Physical Address Space

www.DataSheet4U.com Rev. 5.0, 09/03, page 275 of 806

| Area | Connectable Memory | Physical Address | Capacity | Access Size |
|-----------------|---------------------------------|--|-----------|----------------------------|
| 0 | Ordinary memory ^{*1} , | H'00000000 to H'03FFFFFF | 64 Mbytes | 8, 16, 32 ^{*2} |
| | burst ROM | H'00000000 + H'20000000 × n to H'03FFFFFF + H'20000000 × n | Shadow | n = 1–6 |
| 1 | Internal I/O registers*7 | H'04000000 to H'07FFFFFF | 64 Mbytes | 8, 16, 32 ^{*3} |
| | | H'04000000 + H'20000000 × n to H'07FFFFF + H'20000000 × n | Shadow | n = 1–6 |

| | synchronous DRAM | H'08000000 + H'20000000 × n to H'0BFFFFF + H'20000000 × n | Shadow | n = 1–6 |
| 3 | Ordinary memory, | H'0C000000 to H'0FFFFFF | 64 Mbytes | 8, 16, 32 ^{*3 *4} |
| | synchronous DRAM | $\begin{array}{l} H'0C000000 + H'20000000 \times n \text{ to} \\ H'0FFFFFFF + H'20000000 \times n \end{array}$ | Shadow | n = 1–6 |
| 4 | Ordinary memory | H'10000000 to H'13FFFFFF | 64 Mbytes | 8, 16, 32 ^{*3} |
| | | H'10000000 + H'20000000 × n to H'13FFFFFF + H'20000000 × n | Shadow | n = 1–6 |
| 5 | Ordinary memory, | H'14000000 to H'15FFFFFF | 32 Mbytes | 8, 16, 32 ^{*3 *5} |
| | PCMCIA, burst ROM | H'16000000 to H'17FFFFFF | 32 Mbytes | |
| | Ordinary memory, burst ROM | H'14000000 + H'20000000 × n to H'17FFFFFF + H'20000000 × n | Shadow | n = 1–6 |
| 6 | Ordinary memory, | H'18000000 to H'19FFFFFF | 32 Mbytes | 8, 16, 32 ^{*3 *5} |
| | PCMCIA, burst ROM | H'1A000000 to H'1BFFFFFF | | |
| | | H'18000000 + H'20000000 × n to H'1BFFFFF + H'20000000 × n | Shadow | n = 1–6 |
| 7 ^{*6} | Reserved area | H'1C000000 + H'20000000 × n to H'1FFFFFF + H'20000000 × n | | n = 0–7 |

Table 11.3 Physical Address Space Map

Notes: 1. Memory with interface such as SRAM or ROM.

- 2. Use external pin to specify memory bus width.
- 3. Use register to specify memory bus width.
- 4. With synchronous DRAM interfaces, bus width must be 16 or 32 bits.
- 5. With PCMCIA interface, bus width must be 8 or 16 bits.
- 6. Do not access the reserved area. If the reserved area is accessed, correct operation cannot be guaranteed.
- 7. When the control register in area 1 is not used for address translation by the MMU, set the first three bits of the logical address to 101 for allocation to the P2 space.

| Area 0: H'00000000 | Ordinary memory/ burst ROM | |
|---------------------|--------------------------------------|---|
| Area 1: H'04000000 | Internal I/O | |
| Area 2: H'08000000 | Ordinary memory/ | |
| www.DataSheet4U.com | synchronous DRAM | |
| Area 3: H'0C000000 | Ordinary memory/ synchronous DRAM | |
| Area 4: H'10000000 | Ordinary memory | |
| Area 5: H'14000000 | Ordinary memory/ burst ROM/PCMCIA | The PCMCIA interface is shared by the memory and I/O card |
| Area 6: H'18000000 | Ordinary memory/ burst ROM/PCMCIA | The PCMCIA interface is shared by the memory and I/O card |

Figure 11.3 Physical Space Allocation

Memory Bus Width: The memory bus width in the SH7729R can be set for each area. In area 0, external pins can be used to select byte (8 bits), word (16 bits), or longword (32 bits) on power-on reset. The correspondence between the external pins (MD4 and MD3) and the memory size is shown in table below.

| MD4 | MD3 | Memory Size |
|-----|-----|-----------------------|
| 0 | 0 | Reserved (Do not set) |
| 0 | 1 | 8 bits |
| 1 | 0 | 16 bits |
| 1 | 1 | 32 bits |

| Table 11.4 Correspondence between External Pins (MD4 and MD3) and Memory Siz | Table 11.4 | Correspondence betwee | een External Pins (MD | 4 and MD3) and Mer | nory Size |
|--|------------|------------------------------|-----------------------|--------------------|-----------|
|--|------------|------------------------------|-----------------------|--------------------|-----------|

For areas 2–6, byte, word, and longword can be chosen for the bus width using bus control register 2 (BCR2) whenever ordinary memory, ROM, or burst ROM are used. When the synchronous DRAM interface is used, word or longword can be chosen as the bus width.

When the PCMCIA interface is used, set the bus width to byte or word. When synchronous DRAM is connected to both area 2 and area 3, set the same bus width for areas 2 and 3. When using the port function, set each of the bus widths to byte or word for all areas. For more information, see section 11.2.2, Bus Control Register 2 (BCR2).

Shadow Space: Areas 0 and 2–6 are decoded by physical addresses A28–A26, which correspond to areas 000 to 110. Address bits 31–29 are ignored. This means that the range of area 0 addresses, for example, is H'00000000 to H'03FFFFFF, and its corresponding shadow space is the address space obtained by adding to it H'20000000 × n (n = 1–6). The address range for area 7, which is on-chip I/O space, is H'1C000000 to H'1FFFFFFF. The address space H'1C000000 + H'20000000 × n–H'1FFFFFFF + H'20000000 × n (n = 0–7) corresponding to the area 7 shadow space is reserved, and must not be used.

11.1.6 PCMCIA Support

The SH7729R supports PCMCIA standard interface specifications in physical space areas 5 and 6.

| Item | Feature |
|--------------------|--|
| Access | Random access |
| Data bus | 8/16 bits |
| Memory type | Mask ROM, OTPROM, EPROM, EEPROM, flash memory, SRAM |
| Memory capacity | Maximum 32 Mbytes |
| I/O space capacity | Maximum 32 Mbytes |
| Other features | Dynamic bus sizing of I/O bus width [*] The PCMCIA interface can be accessed from the address translation area or non-address translation area. |

 Table 11.5
 PCMCIA Interface Characteristics

Note: * Dynamic bus sizing of the I/O bus width is supported only in little-endian mode.

| Area 5: H'14000000 | Common memory/Attribute memory | |
|--------------------|--------------------------------|--|
| Area 5: H'1600000 | I/O space | |
| Area 6: H'18000000 | Common memory/Attribute memory | |
| Area 6: H'1A000000 | I/O space | |

11.2 BSC Registers

11.2.1 Bus Control Register 1 (BCR1)

Bus control register 1 (BCR1) is a 16-bit readable/writable register that sets the functions and bus cycle state for each area. It is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or in standby mode. Do not access external memory outside area 0 until BCR1 register initialization is complete.

| | Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|------|------------|--------|--------|--------|-----------------|--------|--------|--------|--------|
| | | PULA | PULD | HIZMEM | HIZCNT | ENDIAN | A0BST1 | A0BST0 | A5BST1 |

| Init | ial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| | | | | / | - -> · · | | | | |

Note: * Samples the value of the external pin (MD5) designating the endian in a power-on reset.

Bit 15—Pin A25 to A0 Pull-Up (PULA): Specifies whether or not pins A25 to A0 are pulled up for 4 cycles immediately after **BACK** is asserted.

| Bit 15: PULA | Description | |
|--------------|---------------|-----------------|
| 0 | Not pulled up | (Initial value) |
| | Pulled up | |

Bit 14—Pin D31 to D0 Pull-Up (PULD): Specifies whether or not pins D31 to D0 are pulled up when not in use.

| Bit 14: PULD | Description | |
|--------------|---------------|-----------------|
| 0 | Not pulled up | (Initial value) |
| 1 | Pulled up | |

Bit 13—Hi-Z Memory Control (HIZMEM): Specifies the state of A25–A0, \overline{BS} , \overline{CS} , RD/WR, \overline{WE} /DQM, \overline{RD} , $\overline{CE2A}$, $\overline{CE2B}$ and DRAK0/1 in standby mode.

| Bit 13: HIZMEM | Description |
|----------------|---------------------------------------|
| 0 | High impedance (Hi-Z) in standby mode |
| 1 | Driven in standby mode |

Bit 12—High-Z Control (HIZCNT): Specifies the state of the \overline{RAS} and \overline{CAS} signals in standby mode and when the bus is released.

| Bit 12: HIZCNT | Description | |
|----------------|--|-----------------|
| 0 | RAS and CAS signals are high-impedance (High-Z) in standby mode and when bus is released (Initial val) (Initial val) | |
| 1 | $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ signals are driven in standby mode and when | bus is released |

Bit 11—Endian Flag (ENDIAN): Samples the value of the external pin designating the endian in a power-on reset. The endian for all physical spaces is decided by this bit, which is read-only.

| Bit 11: ENDIAN | Description |
|----------------|---|
| 0 | (On reset) Endian setting external pin (MD5) is low. Indicates the SH7729R is set as big-endian |
| 1 | (On reset) Endian setting external pin (MD5) is high. Indicates the SH7729R is set as little-endian |

Bits 10 and 9—Area 0 Burst ROM Control (A0BST1, A0BST0): Specify whether to use burst ROM in physical space area 0. When burst ROM is used, these bits set the number of burst transfers.

| Bit 10: A0BST1 | Bit 9: A0BST0 | Description |
|----------------|-----------------|---|
| 0 www.DataS | 0 neet4U.com | Access area 0 accessed as ordinary memory (Initial value) |
| | 1 | Access area 0 accessed as burst ROM (4 consecutive accesses). Can be used when bus width is 8, 16, or 32 |
| 1 | 0 | Access area 0 accessed as burst ROM (8 consecutive accesses). Can be used only when bus width is 8 or 16. Bus width of 32 should not be selected when this setting is used |
| | 1 | Access area 0 accessed as burst ROM (16 consecutive accesses). Can be used only when bus width is 8. Bus width of 16 or 32 should not be selected when this setting is used |

Bits 8 and 7—Area 5 Burst Enable (A5BST1, A5BST0): Specify whether to use burst ROM and PCMCIA burst mode in physical space area 5. When burst ROM and PCMCIA burst mode are used, these bits set the number of burst transfers.

| Bit 8: A5BST1 | Bit 7: A5BST0 | Description |
|---------------|---------------|--|
| 0 | 0 | Access area 5 accessed as ordinary memory (Initial value) |
| | 1 | Burst access of area 5 (4 consecutive accesses). Can be used when bus width is 8, 16, or 32 |
| 1 | 0 | Burst access of area 5 (8 consecutive accesses). Can be used only when bus width is 8 or 16. Bus width of 32 should not be selected when this setting is used |
| | 1 | Burst access of area 5 (16 consecutive accesses). Can be used only when bus width is 8. Bus width of 16 or 32 should not be selected when this setting is used |

Bits 6 and 5—Area 6 Burst Enable (A6BST1, A6BST0): Specify whether to use burst ROM and PCMCIA burst mode in physical space area 6. When burst ROM and PCMCIA burst mode are used, these bits set the number of burst transfers.

| Bit 6: A6BST1 | Bit 5: A6BST0 | Description | | |
|----------------|------------------|--|--|--|
| 0 | 0 | Access area 6 accessed as ordinary memory (initial value) | | |
| | 1 | Burst access of area 6 (4 consecutive accesses). Can be used when bus width is 8, 16, or 32 | | |
| 1 www.Datas | 0 Sheet4U.com | Burst access of area 6 (8 consecutive accesses). Can be used only when bus width is 8 or 16. Bus width of 32 should not be selected when this setting is used | | |
| | 1 | Burst access of area 6 (16 consecutive accesses). Can be used only when bus width is 8. Bus width of 16 or 32 should not be selected when this setting is used | | |

Bits 4 to 2—Area 2, Area 3 Memory Type (DRAMTP2, DRAMTP1, DRAMTP0): Designate the types of memory connected to physical space areas 2 and 3. Ordinary memory, such as ROM, SRAM, or flash ROM, can be directly connected. Synchronous DRAM can also be directly connected.

DILO. DDAMTDO

December (I.e.)

| Bit 4: DRAMTP2 | Bit 3: DRAMTP1 | Bit 2: DRAMTPU | Description |
|----------------|----------------|----------------|---|
| 0 | 0 | 0 | Areas 2 and 3 are ordinary memory (Initial value) |
| | | 1 | Reserved (Setting prohibited) |
| | 1 | 0 | Area 2: ordinary memory; area 3: synchronous DRAM ^{*2} |
| | | 1 | Areas 2 and 3 are synchronous DRAM ^{*1 *2} |
| 1 | 0 | 0 | Reserved (Setting prohibited) |
| | | 1 | Reserved (Setting prohibited) |
| | 1 | 0 | Reserved (Setting prohibited) |
| | | 1 | Reserved (Setting prohibited) |

Notes: 1. When selecting this mode, set the same bus width for area 2 and area 3.

2. Do not access synchronous DRAM when clock ratio $I\phi:B\phi = 1:1$.

Bit 1—Area 5 Bus Type (A5PCM): Designates whether to access physical space area 5 as PCMCIA space.

| Bit 1: A5PCM | Description | |
|--------------|---|-----------------|
| 0 | Physical space area 5 accessed as ordinary memory | (Initial value) |
| 1 | Physical space area 5 accessed as PCMCIA space | |

Bit 0—Area 6 Bus Type (A6PCM): Designates whether to access physical space area 6 as PCMCIA space.

| 0 | Physical space area 6 accessed as ordinary memory | (Initial value) |
| 1 | Physical space area 6 accessed as PCMCIA space | |

11.2.2 Bus Control Register 2 (BCR2)

Bus control register 2 (BCR2) is a 16-bit readable/writable register that selects the bus size of each area. It is initialized to H'3FF0 by a power-on reset, but is not initialized by a manual reset or in standby mode. Do not access external memory outside area 0 until BCR2 register initialization is complete.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | | | A6SZ1 | A6SZ0 | A5SZ1 | A5SZ0 | A4SZ1 | A4SZ0 |

| | 1 | | Longword (32-bit) size |
| 0 | 0 | Used | Reserved (Setting prohibited) |
| | 1 | | Byte (8-bit) size |
| 1 | 0 | | Word (16-bit) size |
| | 1 | | Reserved (Setting prohibited) |

11.2.3 Wait State Control Register 1 (WCR1)

Wait state control register 1 (WCR1) is a 16-bit readable/writable register that specifies the number of idle (wait) state cycles inserted for each area. For some memories, data bus drive may not be turned off quickly even when the read signal from the external device is turned off. This can result in conflicts between data buses when consecutive memory accesses are to different memories or when a write immediately follows a memory read. The SH7729R automatically inserts the number of idle states set in WCR1 in those cases.

WCR1 is initialized to H'3FF3 by a power-on reset. It is not initialized by a manual reset or in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-------------|-------|-------|-------|-------|-------|-------|-------|
| | WAITSE L | _ | A6IW1 | A6IW0 | A5IW1 | A5IW0 | A4IW1 | A4IW0 |

| R/W: | R/W | R/W | R/W | R/W | R | R | R/W | R/W |

Bit 15—WAIT Sampling Timing Select (WAITSEL): Specifies the WAIT signal sampling timing.

Bit 15: WAITSEL Description

| 0 | Setting to 1 when using the WAIT signal [*] | (Initial value) |
|---|--|-----------------|
| 1 | Sampled WAIT signal at fall of CKIO | |
| | | |

Note: * Operation is not guaranteed if \overline{WAIT} is asserted while WAITSEL = 0.

Bits 14, 3, and 2 — Reserved: These bits are always read as 0. The write value should always be 0.

Bits 2n + 1, 2n—Area n (6–2, 0) Intercycle Idle Specification (AnIW1, AnIW0): Specify the number of idles inserted between bus cycles when switching between physical space area n (6–2, 0) and another space or between a read access and a write access in the same physical space.

| Bit 2 | n + 1: AnIW1 Bit | t 2n: AnIW0 | Description | |
|-------|------------------|-------------|------------------------|-----------------|
| 0 | 0 | | 1 idle cycle inserted | |
| | www.DataSheet40. | COM | 1 idle cycle inserted | |
| 1 | 0 | | 2 idle cycles inserted | |
| | 1 | | 3 idle cycles inserted | (Initial value) |

11.2.4 Wait State Control Register 2 (WCR2)

Wait state control register 2 (WCR2) is a 16-bit readable/writable register that specifies the number of wait state cycles inserted for each area. It also specifies the data access pitch for burst memory accesses. This allows direct connection of even low-speed memories without an external circuit. WCR2 is initialized to H'FFFF by a power-on reset. It is not initialized by a manual reset or in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | A6 W2 | A6 W1 | A6 W0 | A5 W2 | A5 W1 | A5 W0 | A4 W2 | A4 W1 |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

11.2.5 Individual Memory Control Register (MCR)

The individual memory control register (MCR) is a 16-bit readable/writable register that specifies \overline{RAS} and \overline{CAS} timing and burst control for synchronous DRAM (areas 2 and 3), specifies address multiplexing, and controls refresh. This enables direct connection of synchronous DRAM without external circuits.

www.DataSheet4U.com

MCR is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or in standby mode. Bits TPC1–TPC0, RCD1–RCD0, TRWL1–TRWL0, TRAS1–TRAS0, RASD, BE, AMX2–AMX0, and EDOMODE are written to in the initialization after a power-on reset and should not then be modified again. When RFSH and RMODE are written to, write the same values to the other bits. When using synchronous DRAM, do not access areas 2 and 3 until this register is initialized.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|------|------|------|------|-------|-------|-------|-------|
| | TPC1 | TPC0 | RCD1 | RCD0 | TRWL1 | TRWL0 | TRAS1 | TRAS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | RASD | AMX3 | AMX2 | AMX1 | AMX0 | RFSH | RMODE | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R |

Bits 15 and 14—RAS Precharge Time (TPC1, TPC0): When synchronous DRAM interface is selected as connected memory, they set the minimum number of cycles until output of the next bank-active command after precharge. However, the number of cycles input immediately after the issue of an all-bank-precharge command (PALL) in the case of an auto-refresh or a precharge command (PRE) in the bank active mode is one fewer than the normal value. TPC1 should not be set to 0 and TPC0 to 1 in the bank active mode.

| | | | Description | |
|-----------------|-----------------|-------------------------|---|-----------------------------------|
| Bit 15: TPC1 | Bit 14: TPC0 | Normal Operation | Immediately after Precharge Command [*] | Immediately after Self-Refresh |
| 0 | 0 | 1 cycle (Initial value) | 0 cycle (Initial value) | 2 cycles (Initial value) |
| | 1 | 2 cycles | 1 cycle | 5 cycles |
| 1 | 0 | 3 cycles | 2 cycles | 8 cycles |
| | 1 | 4 cycles | 3 cycles | 11 cycles |

Note: * Immediately after all-bank-precharge (PALL) in the case of an auto-refresh or precharge (PRE) in the bank active mode.

Bits 13 and 12—RAS–CAS Delay (RCD1, RCD0): When synchronous DRAM interface is selected as connected memory, these bits set the bank active read/write command delay time.

| Bit 13: RCD1 | Bit 12: RCD0 | Description | |
|--------------|--------------------|-------------|-----------------|
| 0 | 0 | 1 cycle | (Initial value) |
| | 1 Shoot/III.com | 2 cycles | |
| 1 | 0 | 3 cycles | |
| | 1 | 4 cycles | |

Bits 11 and 10—Write-Precharge Delay (TRWL1, TRWL0): Set the synchronous DRAM write-precharge delay time. This designates the time between the end of a write cycle and the next bank-active command. This setting is valid only when synchronous DRAM is connected. After the write cycle, the next bank-active command is not issued for the period TPC + TRWL.

| Bit 11: TRWL1 | Bit 10: TRWL0 | Description | |
|---------------|---------------|-------------------------------|-----------------|
| 0 | 0 | 1 cycle | (Initial value) |
| | 1 | 2 cycles | |
| 1 | 0 | 3 cycles | |
| | 1 | Reserved (Setting prohibited) | |

Bits 9 and 8-CAS-Before-RAS Refresh RAS Assert Time (TRAS1, TRAS0): When

synchronous DRAM interface is selected as a connected memory, no bank-active command is issued during the period TPC + TRAS after an auto-refresh command.

| Bit 9: TRAS1 | Bit 8: TRAS0 | Description | |
|--------------|--------------|-------------|-----------------|
| 0 | 0 | 2 cycles | (Initial value) |
| | 1 | 3 cycles | |
| 1 | 0 | 4 cycles | |
| | 1 | 5 cycles | |

Bit 7—Synchronous DRAM Bank Active (RASD): Specifies whether synchronous DRAM is used in bank active mode or auto-precharge mode. Set auto-precharge mode when areas 2 and 3 are both designated as synchronous DRAM space. The bank active mode should not be used unless the bus width for all areas is 32 bits.

| Bit 7: RASD | Description | |
|-------------|---------------------|-----------------|
| 0 | Auto-precharge mode | (Initial value) |
| 1 | Bank active mode | |

Bits 6 to 3—Address Multiplex (AMX3, AMX2, AMX1, AMX0): Specify address multiplexing for synchronous DRAM.

For Synchronous DRAM Interface:

| Bit6: AMX3 | Bit5: AMX2 | Bit 4: AMX1 | Bit 3: AMX0 | Description |
|---------------|---------------|----------------|----------------|---|
| 1 1 | | 0 | 1 | The row address begins with A10 (The A10 value is output at A1 when the row address is output. $4M \times 16$ -bit $\times 4$ -bank products) |
| | | 1 | 0 | The row address begins with A11 (The A11 value is output at A1 when the row address is output. $8M \times 16$ -bit \times 4-bank products) ^{*1} |
| 0 | 1 | 0 | 0 | The row address begins with A9 (The A9 value is output at A1 when the row address is output. $1M \times 16$ -bit $\times 4$ -bank products) (Initial value) |
| | | | 1 | The row address begins with A10 (The A10 value is output at A1 when the row address is output. $2M \times 8$ -bit $\times 4$ -bank products, $2M \times 16$ -bit $\times 4$ -bank products) |
| | | 1 | 1 | The row address begins with A9 (The A9 value is output at A1 when the row address is output. $512k \times 32$ -bit \times 4-bank products) *2 |
| 0 | 0 | 0 | 0 | Begin synchronous DRAM access after setting AMX3 to 0 = *1** |
| Values | except al | oove | | Reserved (Setting prohibited) |

Notes: 1. Can only be set when using a 16-bit bus width.

2. Can only be set when using a 32-bit bus width.

Bit 2—Refresh Control (RFSH): The RFSH bit determines whether or not synchronous DRAM refresh operations are is performed. If the refresh function is not used, the timer for generation of periodic refresh requests can also be used as an interval timer.

| Bit 2: RFSH | Description | |
|-------------|-------------|-----------------|
| 0 | No refresh | (Initial value) |
| 1 | Refresh | |

Bit 1—Refresh Mode (RMODE): Selects whether to perform an ordinary refresh or a selfrefresh when the RFSH bit is 1. When the RFSH bit is 1 and this bit is 0, an auto-refresh is performed on synchronous DRAM at the period set by refresh-related registers RTCNT, RTCOR, and RTCSR. When a refresh request occurs during an external bus cycle, the refresh cycle is performed after the bus cycle ends. When the RFSH bit is 1 and this bit is also 1, the synchronous DRAM will wait for the end of any executing external bus cycle before going into a self-refresh. All refresh requests to memory that is in the self-refresh state are ignored.

| Bit 1: RMODE | Description | |
|--------------|-------------------------------|-----------------|
| 0 | Auto refresh (RFSH must be 1) | (Initial value) |
| 1 | Self-refresh (RFSH must be 1) | |

Bit 0-Reserved: This bit is always read as 0. The write value should always be 0.

11.2.6 PCMCIA Control Register (PCR)

The PCMCIA control register (PCR) is a 16-bit readable/writable register that specifies the assertion and negation timing of the \overline{OE} and \overline{WE} signals for the PCMCIA interface connected to areas 5 and 6. The \overline{OE} and \overline{WE} signal assertion width is set by the wait control bits in the WCR2 register.

PCR is initialized to H'0000 by a power-on reset, but is not initialized, and retains its contents, in a manual reset and in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|--------|--------|--------|--------|--------|--------|--------|--------|
| | A6W3 | A5W3 | — | _ | A5TED2 | A6TED2 | A5TEH2 | A6TEH2 |

| 1 | 1 | 1 | 1 | 38 | Enabled | 39 | Enabled |

Bit 14—Area 5 Wait Control (A5W3): Specifies the number of inserted wait states for area 5 combined with bits A5W2–A5W0 in WCR2. Also specifies the number of transfer states in burst transfer. Clear this bit to 0 when area 5 is not set to PCMCIA.

The relationship between the set value and the number of waits is the same as for A6W3.

Bits 13 and 12—Reserved: These bits are always read as 0. The write value should always be 0.

www.DataSheet4U.com Rev. 5.0, 09/03, page 295 of 806

Bits 11, 7, and 6—Area 5 Address \overline{OE}/\overline{WE} Assert Delay (A5TED2, A5TED1, A5TED0): Specify the delay time from address output to $\overline{OE}/\overline{WE}$ assertion for the PCMCIA interface connected to area 5.

| Bit 11: A5TED2 | Bit 7: A5TED1 | Bit 6: A5TED0 | Description | |
|-------------------|----------------------|------------------|-----------------|-----------------|
| 0 ww | w @ ataSheet4 | L 0 com | 0.5-cycle delay | (Initial value) |

| | | 1 | 7.5-cycle delay | |

11.2.7 Synchronous DRAM Mode Register (SDMR)

The synchronous DRAM mode register (SDMR) is an 8-bit write-only register that is written to via the synchronous DRAM address bus. It sets synchronous DRAM mode for areas 2 and 3. SDMR is undefined after a power-on reset. The register contents are not initialized by a manual reset or in standby mode; values remain unchanged.

www.DataSheet4U.com

Writes to the synchronous DRAM mode register use the address bus rather than the data bus. If the value to be set is X and the SDMR address is Y, the value X is written in the synchronous DRAM mode register by writing in address X + Y. Since, with a 32-bit bus width, A0 of the synchronous DRAM is connected to A2 of the chip and A1 of the synchronous DRAM is connected to A3 of the chip, the value actually written to the synchronous DRAM is the X value shifted two bits right. With a 16-bit bus width, the value written is the X value shifted one bit right. For example, with a 32-bit bus width, when H'0230 is written to the SDMR register of area 2, random data is written to the address H'FFFFD000 (address Y) + H'08C0 (value X), or H'FFFFD8C0. As a result, H'0230 is written to the SDMR register. The range for value X is H'0000 to H'0FFC. When H'0230 is written to the SDMR register of area 3, random data is written to the address H'FFFFE000 (address Y) + H'08C0 (value X), or H'FFFFE8C0. As a result, H'0230 is written to the SDMR register. The range for value X is

Note: * Depending on the type of synchronous DRAM.

11.2.8 Refresh Timer Control/Status Register (RTCSR)

The refresh timer control/status register (RTCSR) is a 16-bit readable/writable register that specifies the refresh cycle, whether to generate an interrupt, and the cycle of that interrupt. It is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or in standby mode. Make the RTCOR setting before setting bits CKS2 to CKS0 in RTCSR.

vw.DataSheet4U.com

Note: The method of writing to RTCSR differs from that for general registers to ensure that RTCSR is not rewritten incorrectly. Use a word transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For details, see section 11.2.12, Cautions on Accessing Refresh Control Related Registers.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-----|------|------|------|------|-----|------|------|
| | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | CMF | CMIE | CKS2 | CKS1 | CKS0 | OVF | OVIE | LMTS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15 to 8—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 7—Compare Match Flag (CMF): Indicates that the values of RTCNT and RTCOR match.

| Bit 7: CMF | Description | |
|------------|---|-----------------|
| 0 | The values of RTCNT and RTCOR do not match | (Initial value) |
| | Clearing condition: When a refresh is performed after 0 h CMF and RFSH = 1 and RMODE = 0 (to perform a CBR | |
| 1 | The values of RTCNT and RTCOR match | |
| | Setting condition: RTCNT = RTCOR* | |

Note: * Contents do not change when 1 is written to CMF.

Bit 6—Compare Match Interrupt Enable (CMIE): Enables or disables an interrupt request caused when CMF in RTCSR is set to 1. Do not set this bit to 1 when using auto-refresh.

| Bit 6: CMIE | Description | |
|-------------|--------------------------------------|-----------------|
| 0 | Interrupt request by CMF is disabled | (Initial value) |
| 1 | Interrupt request by CMF is enabled | |

www.DataSheet4U.com Rev. 5.0, 09/03, page 299 of 806

Bits 5 to 3—Clock Select Bits (CKS2 to CKS0): Select the clock input to RTCNT. The source clock is the external bus clock (BCLK). The RTCNT count clock is CKIO divided by the specified ratio. RTCOR must be set before setting CKS2–CKS0.

| | | | Description |
|-------------|-------------|-------------|---------------------------|
| Bit 5: CKS2 | Bit 4: CKS1 | Bit 3: CKS0 | Normal external bus clock |
| 0 | 0 | 0 | Clock input disabled |
| | | 1 | Bus clock (CKIO)/4 |
| | 1 | 0 | CKIO/16 |
| | | 1 | CKIO/64 |
| 1 | 0 | 0 | CKIO/256 |
| | | 1 | CKIO/1024 |
| | 1 | 0 | CKIO/2048 |
| | | 1 | CKIO/4096 |

Bit 2—Refresh Count Overflow Flag (OVF): Indicates when the number of refresh requests indicated in the refresh count register (RFCR) exceeds the limit set in the LMTS bit in RTCSR.

| Bit 2: OVF | Description | |
|------------|---|-------------------|
| 0 | RFCR has not exceeded the count limit value set in LMTS | (Initial value) |
| | Clearing condition: When 0 is written to OVF | |
| 1 | RFCR has exceeded the count limit value set in LMTS | |
| | Setting condition: When the RFCR value has exceeded the or set in LMTS $^{\!$ | count limit value |

Note: * Contents do not change when 1 is written to OVF.

Bit 1—Refresh Count Overflow Interrupt Enable (OVIE): Selects whether to suppress generation of interrupt requests by the OVF bit in RTCSR when OVF is set to 1.

| Bit 1: OVIE | Description | |
|-------------|--------------------------------------|-----------------|
| 0 | Interrupt request by OVF is disabled | (Initial value) |
| 1 | Interrupt request by OVF is enabled | |

Bit 0—Refresh Count Overflow Limit Select (LMTS): Indicates the count limit value to be compared to the number of refreshes indicated in the refresh count register (RFCR). When the value in RFCR overflows the value specified by LMTS, the OVF flag is set.

| Bit 0: LMTS | Description | |
|-----------------|---------------------------|-----------------|
| 0 | Count limit value is 1024 | (Initial value) |
| 1 www.DataSheet | Count limit value is 512 | |

11.2.9 Refresh Timer Counter (RTCNT)

RTCNT is a 16-bit register containing a readable/writable 8-bit counter that counts up on an input clock. The clock select bits (CKS2–CKS0) in RTCSR select the input clock. When RTCNT matches RTCOR, the CMF bit in RTCSR is set and RTCNT is cleared. RTCNT is initialized to H'00 by a power-on reset, but continues incrementing after a manual reset. It is not initialized in standby mode, but holds its contents.

Note: The method of writing to RTCNT differs from that for general registers to ensure that RTCNT is not rewritten incorrectly. Use a word transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For details, see section 11.2.12, Cautions on Accessing Refresh Control Related Registers.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|
| | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | — | — | — | — | — | — | — | — |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W |

11.2.10 Refresh Time Constant Register (RTCOR)

The refresh time constant register (RTCOR) is a 16-bit register with a readable/writable lower 8 bits. The values of RTCOR and RTCNT (lower 8 bits) are constantly compared. When the values match, the compare match flag (CMF) in RTCSR is set and RTCNT is cleared to 0. When the refresh bit (RFSH) in the individual memory control register (MCR) is set to 1 and the refresh mode is set to auto refresh, a memory refresh cycle occurs when the CMF bit is set. RTCOR is initialized to H'00 by a power-on reset. It is not initialized by a manual reset or in standby mode, but holds its contents. Make the RTCOR setting before setting bits CKS2 to CKS0 in RTCSR.

Note: The method of writing to RTCOR differs from that for general registers to ensure that RTCOR is not rewritten incorrectly. Use a word transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For details, see section 11.2.12, Cautions on Accessing Refresh Control Related Registers.

11.2.11 Refresh Count Register (RFCR)

The refresh count register (RFCR) is a 16-bit register containing a readable/writable 10-bit counter that increments every time RTCOR and RTCNT match. When RFCR exceeds the count limit value set in the LMTS bit in RTCSR, the OVF bit in RTCSR is set and RFCR is cleared. RFCR is initialized to H'0000 by a power-on reset. It is not initialized by a manual reset or in standby mode, but holds its contents.

Note: The method of writing to RFCR differs from that for general registers to ensure that RFCR is not rewritten incorrectly. Use a word transfer instruction to set the six bits starting from the MSB in the upper byte as B'101001, and the remaining bits as the write data. For details, see section 11.2.12, Cautions on Accessing Refresh Control Related Registers.

11.2.12 Cautions on Accessing Refresh Control Related Registers

RFCR, RTCSR, RTCNT, and RTCOR require that a specific code be appended to the data when it is written to prevent data from being mistakenly overwritten by program overruns or other write operations (figure 11.5). Perform reads and writes using the following methods:

1. When writing to RFCR, RTCSR, RTCNT, and RTCOR, use only word transfer instructions. Byte transfer instructions cannot be used.

When writing to RTCNT, RTCSR, or RTCOR, place B'10100101 in the upper byte and the write data in the lower byte. When writing to RFCR, place B'101001 in the upper 6 bits and the write data in the remaining bits, as shown in figure 11.5.

2. When reading from RFCR, RTCSR, RTCNT, and RTCOR, carry out reads with a 16-bit width. 0 is read from undefined bits.

Figure 11.5 Writing to RFCR, RTCSR, RTCNT, and RTCOR

11.2.13 MCS0 Control Register (MCSCR0)

The MCS0 control register (MCSCR0) is a 16-bit readable/writable register that specifies the $\overline{\text{MCS}[0]}$ pin output conditions.

MCSCR0 is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or in standby mode ataSheet4U.com

As the $\overline{\text{MCS}[0]}$ pin is multiplexed as the PTC0 pin, when using the pin as $\overline{\text{MCS}[0]}$, bits PC0MD[1:0] in the PCCR register should be set to 00 (other function).

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-----|-------|------|------|-----|-----|-----|-----|
| | — | _ | — | | — | — | _ | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | CS2/0 | CAP1 | CAP0 | A25 | A24 | A23 | A22 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15 to 7—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 6—CS2/CS0 Select (CS2/0): Selects whether an area 2 or area 0 address is to be decoded.

| Bit 6: CS2/0 | Description |
|--------------|--------------------|
| 0 | Area 0 is selected |
| 1 | Area 2 is selected |

Note that the CS2/0 bit in MCSCR should always be cleared to 0 (area 0 selected).

Bits 5 and 4—Connected Memory Size Specification (CAP1, CAP0)

| Bit 5: CAP1 | Bit 4: CAP0 | Description |
|-------------|-------------|------------------------------|
| 0 | 0 | 32-Mbit memory is connected |
| 0 | 1 | 64-Mbit memory is connected |
| 1 | 0 | 128-Mbit memory is connected |
| 1 | 1 | 256-Mbit memory is connected |

Bits 3 to 0—Start Address Specification (A25, A24, A23, A22): These bits specify the start address of the memory area for which $\overline{MCS[0]}$ is asserted.

www.DataSheet4U.com

11.2.14 MCS1 Control Register (MCSCR1)

The MCS1 control register (MCSCR1) specifies the $\overline{MCS[1]}$ pin output conditions.

The bit configuration and functions are the same as those of MCSCR0.

11.2.15 MCS2 Control Register (MCSCR2)

The MCS2 control register (MCSCR2) specifies the $\overline{\text{MCS}[2]}$ pin output conditions. The bit configuration and functions are the same as those of MCSCR0.

11.2.16 MCS3 Control Register (MCSCR3)

The MCS3 control register (MCSCR3) specifies the $\overline{\text{MCS}[3]}$ pin output conditions. The bit configuration and functions are the same as those of MCSCR0.

11.2.17 MCS4 Control Register (MCSCR4)

The MCS4 control register (MCSCR4) specifies the $\overline{\text{MCS}[4]}$ pin output conditions. The bit configuration and functions are the same as those of MCSCR0.

11.2.18 MCS5 Control Register (MCSCR5)

The MCS5 control register (MCSCR5) specifies the $\overline{\text{MCS}[5]}$ pin output conditions. The bit configuration and functions are the same as those of MCSCR0.

11.2.19 MCS6 Control Register (MCSCR6)

The MCS6 control register (MCSCR6) specifies the $\overline{\text{MCS}[6]}$ pin output conditions. The bit configuration and functions are the same as those of MCSCR0.

11.2.20 MCS7 Control Register (MCSCR7)

The MCS7 control register (MCSCR7) specifies the $\overline{MCS[7]}$ pin output conditions.

The bit configuration and functions are the same as those of MCSCR0.

www.DataSheet4U.com Rev. 5.0, 09/03, page 305 of 806

11.3 BSC Operation

11.3.1 Endian/Access Size and Data Alignment

The SH7729R supports both big endian, in which the 0 address is the most significant byte in the byte data, and little endian, in which the 0 address is the least significant byte. Switching between the two is designated by an external pin (MD5 pin) at the time of a power-on reset. After a power-on reset, big endian is engaged when MD5 is low; little endian is engaged when MD5 is high.

Three data bus widths are available for ordinary memory (byte, word, longword) and two data bus widths (word and longword) for synchronous DRAM. For the PCMCIA interface, choose from byte and word. This means data alignment is done by matching the device's data width and endian. The access unit must also be matched to the device's bus width. This also means that when longword data is read from a byte-width device, four read operations must be performed. In the SH7729R, data alignment and conversion of data length is performed automatically between the respective interfaces.

Tables 11.7 to 11.12 show the relationship between endian, device data width, and access unit.

| | | Data I | Bus | | Strobe Signals | | | | |

Table 11.12 8-Bit External Device/Little-Endian Access and Data Alignment

11.3.2 Description of Areas

Area 0: Area 0 physical address bits A28–A26 are 000. Address bits A31–A29 are ignored and the address range is H'00000000 + H'20000000 × n - H'03FFFFFF + H'20000000 × n (n = 0-6) and n = 1-6 are the shadow spaces).

Ordinary memories such as SRAM, ROM, and burst ROM can be connected to this space. Byte, word, or longword can be selected as the bus width using external pins MD3 and MD4. When the area 0 space is accessed, the $\overline{CS0}$ signal is asserted. The \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}-\overline{WE3}$ signals for write control are also asserted. The number of bus cycles is selected between 0 and 10 wait cycles using the A0W2–A0W0 bits in WCR2. When the burst function is used, the bus cycle pitch of the burst cycle is determined within a range of 2–10 according to the number of waits.

Area 1: Area 1 physical address bits A28–A26 are 001. Address bits A31–A29 are ignored and the address range is H'04000000 + H'20000000 × n - H'07FFFFFF + H'20000000 × n (n = 0-6) and n = 1-6 are the shadow spaces).

Area 1 is the area specifically for internal peripheral modules. External memories cannot be connected.

Control registers of the peripheral modules shown below are mapped to this area 1. Their addresses are physical addresses, to which logical addresses can be mapped when the MMU is enabled:

DMAC, PORT, IrDA, SCIF, ADC, DAC, INTC (except INTEVT, IPRA, IPRB)

These registers must be set not to be cached.

Area 2: Area 2 physical address bits A28–A26 are 010. Address bits A31–A29 are ignored and the address range is H'08000000 + H'20000000 × n - H'0BFFFFFF + H'20000000 × n (n = 0-6 and n = 1-6 are the shadow spaces).

Ordinary memories such as SRAM and ROM, as well as synchronous DRAM, can be connected to this space. Byte, word, or longword can be selected as the bus width using bits A2SZ1 and A2SZ0 in BCR2 for ordinary memory.

When the area 2 space is accessed, the $\overline{CS2}$ signal is asserted. When ordinary memories are connected, the \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}$ – $\overline{WE3}$ signals for write control are also asserted and the number of bus cycles is selected between 0 and 3 wait cycles using bits A2W1 and A2W0 bits in WCR2.

When synchronous DRAM is connected, the $\overline{RAS3U}$ and $\overline{RAS3L}$ signals, \overline{CASU} and \overline{CASL} signals, RD/\overline{WR} signal, and byte control signals DQMHH, DQMHL, DQMLH, and DQMLL are

www.DataSheet4U.com Rev. 5.0, 09/03, page 311 of 806

all asserted and addresses multiplexed. Control of $\overline{RAS3U}$, $\overline{RAS3L}$, \overline{CASU} , \overline{CASL} , data timing, and address multiplexing is set with MCR.

Area 3: Area 3 physical address bits A28–A26 are 011. Address bits A31–A29 are ignored and the address range is H'0C000000 + H'20000000 × n – H'0FFFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces).

```
www.DataSheet4U.com
```

Ordinary memories such as SRAM and ROM, as well as synchronous DRAM, can be connected to this space. Byte, word or longword can be selected as the bus width using bits A3SZ1 and A3SZ0 bits in BCR2 for ordinary memory.

When area 3 space is accessed, $\overline{CS3}$ is asserted.

When ordinary memories are connected, the \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}$ - $\overline{WE3}$ signals for write control are asserted and the number of bus cycles is selected between 0 and 3 wait cycles using the A3W1 and A3W0 bits in WCR2.

When synchronous DRAM is connected, the $\overline{RAS3U}$ and $\overline{RAS3L}$ signals, \overline{CASU} and \overline{CASL} signals, RD/WR signal, and byte control signals DQMHH, DQMHL, DQMLH, and DQMLL are all asserted and addresses multiplexed. The $\overline{RAS3U}$ and $\overline{RAS3L}$ signals, \overline{CASHH} signal, \overline{CASHL} signal, \overline{CASLH} signal, \overline{CASLL} signal, and RD/WR signal are all asserted and addresses multiplexed.

Area 4: Area 4 physical address bits A28–A26 are 100. Address bits A31–A29 are ignored and the address range is H'10000000 + H'20000000 × n – H'13FFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces).

Only ordinary memories such as SRAM and ROM can be connected to this space. Byte, word, or longword can be selected as the bus width using bits A4SZ1 and A4SZ0 in BCR2. When the area 4 space is accessed, the $\overline{CS4}$ signal is asserted. The \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}-\overline{WE3}$ signals for write control are also asserted. The number of bus cycles is selected between 0 and 10 wait cycles using the A4W2–A4W0 bits in WCR2.

The number of bus cycles is selected between 0 and 10 wait cycles using bits A4W2 to A4W0 in WCR2. In addition, any number of wait cycles can be inserted in each bus cycle by means of the external wait pin (\overline{WAIT}).

Area 5: Area 5 physical address bits A28–A26 are 101. Address bits A31–A29 are ignored and the address range is the 64 Mbytes at H'14000000 + H'20000000 × n – H'17FFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces).

Ordinary memories such as SRAM and ROM as well as burst ROM and PCMCIA interfaces can be connected to this space. When the PCMCIA interface is used, the IC memory card interface address range comprises the 32 Mbytes at H'14000000 + H'20000000 × n to H'15FFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces), and the I/O card interface address www.DataSheet4U.com

Rev. 5.0, 09/03, page 312 of 806

range comprises the 32 Mbytes at H'16000000 + H'20000000 × n to H'17FFFFFF + H'20000000 × n (n = 0-6 and n = 1-6 are the shadow spaces).

For ordinary memory and burst ROM, byte, word, or longword can be selected as the bus width using bits A5SZ1 and A5SZ0 in BCR2. For the PCMCIA interface, byte or word can be selected as the bus width using bits A5SZ1 and A5SZ0 bits in BCR2.

www.DataSheet4U.com

When the area 5 space is accessed and ordinary memory is connected, the $\overline{CS5}$ signal is asserted. The \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}$ - $\overline{WE3}$ signals for write control are also asserted. When the PCMCIA interface is used, the $\overline{CE1A}$ signal, $\overline{CE2A}$ signal, \overline{RD} signal as \overline{OE} signal, and $\overline{WE1}$ signal are asserted.

The number of bus cycles is selected between 0 and 10 wait cycles using the A5W2–A5W0 bits in WCR2. With the PCMCIA interface, from 0 to 38 wait cycles can be selected using the A5W2–A5W0 bits in WCR2 and the A5W3 bit in PCR. In addition, any number of waits can be inserted in each bus cycle by means of the external wait pin (WAIT). When a burst function is used, the bus cycle pitch of the burst cycle is determined within a range of 2–11 (2–39 for the PCMCIA interface) according to the number of waits. The setup and hold times of address/ $\overline{CS5}$ for the read/write strobe signals can be set in the range 0.5–7.5 using bits A5TED2–A5TED0 and A5TEH2–A5TEH0 in the PCR register.

Area 6: Area 6 physical address bits A28–A26 are 110. Address bits A31–A29 are ignored and the address range is the 64 Mbytes at H'18000000 + H'20000000 × n – H'1BFFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces).

Ordinary memories such as SRAM and ROM as well as burst ROM and PCMCIA interfaces can be connected to this space. When the PCMCIA interface is used, the IC memory card interface address range is 32 Mbytes at H'18000000 + H'20000000 × n – H'19FFFFFF + H'20000000 × n – H'19FFFFFF + H'20000000 × n – H'18FFFFFF + H'20000000 × n – H'18FFFFFF + H'20000000 × n (n = 0–6 and n = 1–6 are the shadow spaces).

For ordinary memory and burst ROM, byte, word, or longword can be selected as the bus width using bits A6SZ1 and A6SZ0 in BCR2. For the PCMCIA interface, byte or word can be selected as the bus width using bits A6SZ1 and A6SZ0 in BCR2.

When the area 6 space is accessed and ordinary memory is connected, the $\overline{CS6}$ signal is asserted. The \overline{RD} signal that can be used as \overline{OE} and the $\overline{WE0}$ - $\overline{WE3}$ signals for write control are also asserted. When the PCMCIA interface is used, the $\overline{CE1B}$ signal, $\overline{CE2B}$ signal, \overline{RD} signal as \overline{OE} signal, and \overline{WE} , \overline{ICIORD} , and \overline{ICIOWR} signals are asserted.

The number of bus cycles is selected between 0 and 10 wait cycles using the A6W2–A6W0 bits in WCR2. With the PCMCIA interface, from 0 to 38 wait cycles can be selected using the A6W2–A6W0 bits in WCR2 and the A6W3 bit in PCR. In addition, any number of waits can be inserted in each bus cycle by means of the external wait pin (WAIT). The bus cycle pitch of the burst cycle is determined within a range of 2–11 (2–39 for the PCMCIA interface) according to a selected method.

Rev. 5.0, 09/03, page 313 of 806

waits. The address/ $\overline{CS6}$ setup and hold times for the read/write strobe signals can be set in the range 0.5–7.5 using bits A6TED2–A6TED0 and A6TEH2–A6TEH0 in the PCR register.

11.3.3 Basic Interface

Basic Timing: The basic interface of the SH7729R uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. Figure 11.6 shows the basic timing of normal space accesses. A no-wait normal access is completed in two cycles. The \overline{BS} signal is asserted for one cycle to indicate the start of a bus cycle. The \overline{CSn} signal is negated on the T2 clock falling edge to secure the negation period. Therefore, in case of access at minimum pitch, there is a half-cycle negation period.

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 32 bits are always read in case of a 32-bit device, and 16 bits in case of a 16-bit device. When writing, only the \overline{WE} signal for the byte to be written is asserted. For details, see section 11.3.1, Endian/Access Size and Data Alignment.

Read/write for cache fill or write-back follows the set bus width and transfers a total of 16 bytes continuously. The bus is not released during this transfer. For cache misses that occur during byte or word operand accesses or branching to odd word boundaries, the fill is always performed by longword accesses on the chip-external interface. Write-through-area write access and non-cacheable read/write access are based on the actual address size.

www.DataSheet4U.com

Figure 11.6 Basic Timing of Basic Interface

Figures 11.7, 11.8, and 11.9 show examples of connection to 32, 16, and 8-bit data-width static RAM, respectively.

Figure 11.7 Example of 32-Bit Data-Width Static RAM Connection

www.DataSheet4U.com

Figure 11.8 Example of 16-Bit Data-Width Static RAM Connection

Figure 11.9 Example of 8-Bit Data-Width Static RAM Connection

Wait State Control: Wait state insertion on the basic interface can be controlled by the WCR2 settings. If the WCR2 wait specification bits corresponding to a particular area are not zero, a software wait is inserted in accordance with that specification. For details, see section 11.2.4, Wait State Control Register 2 (WCR2).

The specified number of Tw cycles are inserted as wait cycles using the basic interface wait timing shown in figure 11.10.1.com

Figure 11.10 Basic Interface Wait Timing (Software Wait Only)

When software wait insertion is specified by WCR2, the external wait input $\overline{\text{WAIT}}$ signal is also sampled. $\overline{\text{WAIT}}$ pin sampling is shown in figure 11.11. A 2-cycle wait is specified as a software wait. Sampling is performed at the transition from the Tw state to the T₂ state; therefore, if the $\overline{\text{WAIT}}$ signal has no effect if asserted in the T₁ cycle or the first Tw cycle.

www.DataSheet4U.com Rev. 5.0, 09/03, page 319 of 806

When the WAITSEL bit in the WCR1 register is set to 1, the \overline{WAIT} signal is sampled at the falling edge of the clock. If the setup time and hold times with respect to the falling edge of the clock are not satisfied, the value sampled at the next falling edge is used.

However, the \overline{WAIT} signal is ignored in the following three cases:

- A write to external address space in dual address mode with 16-byte DMA transfer
- Transfer from an external device with DACK to external address space in single address mode with 16-byte DMA transfer
- Wait states inserted by WAIT signal Tw Tw Tw T_2 CKIO A25 to A0 CSn RD/WR RD Read D31 to D0 WFn Write D31 to D0 WAIT BS
- Cache write-back access

11.3.4 Synchronous DRAM Interface

Synchronous DRAM Direct Connection: Since synchronous DRAM can be selected by the \overline{CS} signal, physical space areas 2 and 3 can be connected using \overline{RAS} and other control signals in common. If the memory type bits (DRAMTP2–0) in BCR1 are set to 010, area 2 is ordinary memory space and area 3 is synchronous DRAM space; if set to 011, areas 2 and 3 are both synchronous DRAM space. Note, however, that synchronous DRAM must not be accessed when clock ratio I ϕ :B ϕ = 1:1.

With the SH7729R, burst length 1 burst read/single write mode is supported as the synchronous DRAM operating mode. A data bus width of 16 or 32 bits can be selected. The burst enable bit (BE) in MCR is ignored, a 16-bit burst transfer is performed in a cache fill/write-back cycle, and only one access is performed in a write-through area write or a non-cacheable area read/write.

The control signals for direct connection of synchronous DRAM are $\overline{RAS3L}$, $\overline{RAS3U}$, \overline{CASL} , \overline{CASU} , $\overline{RD/WR}$, $\overline{CS2}$ or $\overline{CS3}$, DQMUU, DQMUL, DQMLU, DQMLL, and CKE. All the signals other than $\overline{CS2}$ and $\overline{CS3}$ are common to all areas, and signals other than CKE are valid and fetched to the synchronous DRAM only when CS2 or CS3 is asserted. Synchronous DRAM can therefore be connected in parallel to a number of areas. CKE is negated (low) only when self-refreshing is performed, and is always asserted (high) at other times.

In the refresh cycle and mode-register write cycle, $\overline{RAS3U}$ and $\overline{RAS3L}$ or \overline{CASU} and \overline{CASL} are output.

Commands for synchronous DRAM are specified by RAS3L, RAS3U, CASL, CASU, RD/WR, and special address signals. The commands are NOP, auto-refresh (REF), self-refresh (SELF), precharge all banks (PALL), row address strobe bank active (ACTV), read (READ), read with precharge (READA), write (WRIT), write with precharge (WRITA), and mode register write (MRS).

Byte specification is performed by DQMUU, DQMUL, DQMLU, and DQMLL. A read/write is performed for the byte for which the corresponding DQM is low. In big-endian mode, DQMUU specifies an access to address 4n, and DQMLL specifies an access to address 4n + 3. In little-endian mode, DQMUU specifies an access to address 4n + 3, and DQMLL specifies an access to address 4n + 3.

Figures 11.12 and 11.13 show examples of the connection of two $1M \times 16$ -bit $\times 4$ -bank synchronous DRAMs and one $1M \times 16$ -bit $\times 4$ -bank synchronous DRAM, respectively.

www.DataSheet4U.com Rev. 5.0, 09/03, page 321 of 806

Figure 11.13 Example of 64-Mbit Synchronous DRAM (16-Bit Bus Width)

Address Multiplexing: Synchronous DRAM can be connected without external multiplexing circuitry in accordance with the address multiplex specification bits AMX2-AMX0 in MCR. Table 11.13 shows the relationship between the address multiplex specification bits and the bits output at the address pins.

A25–A16 and A0 are not multiplexed; the original values are always output at these pins.

When A0, the LSB of the synchronous DRAM address, is connected to the SH7729R, it performs longword address specification. Connection should therefore be made in the following order: with a 32-bit bus width, connect pin A0 of the synchronous DRAM to pin A2 of the SH7729R, then connect pin A1 to pin A3; with a 16-bit bus width, connect pin A0 of the synchronous DRAM to pin A1 of the SH7729R, then connect pin A1 to pin A2.

| | | Setting | | | | | External Address Pins | | | | | | | | |

Table 11.14 Example of Correspondence between SH7729R and Synchronous DRAM Address Pins (AMX [3:0] = 0100 (32-Bit Bus Width))

Burst Read: In the example in figure 11.14 it is assumed that four 2M × 8-bit synchronous DRAMs are connected and a 32-bit data width is used, and the burst length is 1. Following the Tr cycle in which ACTV command output is performed, a READ command is issued in the Tc1, Tc2, and Tc3 cycles, and a READA command in the Tc4 cycle, and the read data is accepted at the rising edge of the external command clock (CKIO) from cycle Td1 to cycle Td4. The Tpc cycle is used to wait for completion of auto-precharge based on the READA command inside the synchronous DRAM; no new access command can be issued to the same bank during this cycle, but access to synchronous DRAM for another area is possible. In the SH7729R, the number of Tpc cycles is determined by the TPC bit specification in MCR, and commands cannot be issued for the same synchronous DRAM during this interval.

The example in figure 11.14 shows the basic timing. To connect low-speed synchronous DRAM, the cycle can be extended by setting WCR2 and MCR bits. The number of cycles from the ACTV command output cycle, Tr, to the READ command output cycle, Tc1, can be specified by the RCD bits in MCR, with values of 0 to 3 specifying 1 to 4 cycles, respectively. In case of 2 or more cycles, a Trw cycle, in which an NOP command is issued for the synchronous DRAM, is inserted between the Tr cycle and the Tc cycle. The number of cycles from READ and READA command output cycles Tc1-Tc4 to the first read data latch cycle, Td1, can be specified as 1 to 3 cycles www.DataSheet4U.com

Rev. 5.0, 09/03, page 325 of 806

independently for areas 2 and 3 by means of bits A2W1 and A2W0 or A3W1 and A3W0 in WCR2. This number of cycles corresponds to the number of synchronous DRAM CAS latency cycles.

Figure 11.14 Basic Timing for Synchronous DRAM Burst Read

www.DataSheet4U.com

Figure 11.15 shows the burst read timing when RCD is set to 1, A3W1 and A3W0 are set to 10, and TPC is set to 1.

The BS cycle, which is asserted for one cycle at the start of a bus cycle for normal access space, is asserted in each of cycles Td1–Td4 in a synchronous DRAM cycle. When a burst read is performed, the address is updated each time \overline{CAS} is asserted. As the unit of burst transfer is 16 bytes, address updating is performed for A3 and A2 only (A3, A2, and A1 in the case of a 16-bit bus width). The order of access is as follows: in a fill operation in the event of a cache miss, the missed data is read first, then 16-byte boundary data including the missed data is read in wraparound mode.

Figure 11.15 Synchronous DRAM Burst Read Wait Specification Timing

Single Read: Figure 11.16 shows the timing when a single address read is performed. As the burst length is set to 1 in synchronous DRAM burst read/single write mode, only the required data is output. Consequently, no unnecessary bus cycles are generated even when a cache-through area is accessed.

Figure 11.16 Basic Timing for Synchronous DRAM Single Read

www.DataSheet4U.com

Burst Write: The timing chart for a burst write is shown in figure 11.17. In the SH7729R, a burst write occurs in the event of cache write-back or 16-byte DMAC transfer. In a burst write operation, following the Tr cycle in which ACTV command output is performed, a WRIT command is issued in the Tc1, Tc2, and Tc3 cycles, and a WRITA command that performs autoprecharge is issued in the Tc4 cycle. In the write cycle, the write data is output at the same time as the write command. In case of the write with auto-precharge command, precharging of the relevant bank is performed in the synchronous DRAM after completion of the write command, and therefore no command can be issued for the same bank until precharging is completed. Consequently, in addition to the precharge wait cycle, Tpc, used in a read access, cycle Trwl is also added as a wait interval until precharging is started following the write command. Issuance of a new command for the same bank is deferred during this interval. The number of Trwl cycles can be specified by the TRWL bits in MCR.

Figure 11.17 Basic Timing for Synchronous DRAM Burst Write

www.DataSheet4U.com

Single Write: The basic timing chart for write access is shown in figure 11.18. In a single write operation, following the Tr cycle in which ACTV command output is performed, a WRITA command that performs auto-precharge is issued in the Tc1 cycle. In the write cycle, the write data is output at the same time as the write command. In case of the write with auto-precharge command, precharging of the relevant bank is performed in the synchronous DRAM after completion of the write command, and therefore no command can be issued for the same bank until precharging is completed. Consequently, in addition to the precharge wait cycle, Tpc, used in a read access, cycle Trwl is also added as a wait interval until precharging is started following the write command. Issuance of a new command for the same bank is deferred during this interval. The number of Trwl cycles can be specified by the TRWL bits in MCR.

Figure 11.18 Basic Timing for Synchronous DRAM Single Write

www.DataSheet4U.com

Bank Active: The synchronous DRAM bank function is used to support high-speed accesses to the same row address. When the RASD bit in MCR is 1, read/write command accesses are performed using commands without auto-precharge (READ, WRIT). In this case, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command, in the same way as in the RAS down state in DRAM fast page mode. As synchronous DRAM is internally divided into two or four banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued.

In a write, when auto-precharge is performed, a command cannot be issued for a period of Trwl + Tpc cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by Trwl + Tpc cycles for each write. The number of cycles between issuance of the precharge command and the row address strobe command is determined by the TPC bits in MCR.

Whether faster execution speed is achieved by use of bank active mode or by use of basic access is determined by the probability of accessing the same row address (P1), and the average number of cycles from completion of one access to the next access (Ta). If Ta is greater than Tpc, the delay due to the precharge wait when writing is imperceptible. In this case, the access speed for bank active mode and basic access is determined by the number of cycles from the start of access to issuance of the read/write command: $(Tpc + Trcd) \times (1 - P1)$ and Trcd, respectively.

There is a limit on Tras, the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of Tras. In this way, it is possible to observe the restrictions on the maximum active state time for each bank. If auto-refresh is not used, measures must be taken in the program to ensure that the banks do not remain active for longer than the prescribed time.

A burst read cycle without auto-precharge is shown in figure 11.19, a burst read cycle for the same row address in figure 11.20, and a burst read cycle for different row addresses in figure 11.21. Similarly, a burst write cycle without auto-precharge is shown in figure 11.22, a burst write cycle for the same row address in figure 11.23, and a burst write cycle for different row addresses in figure 11.24.

www.DataSheet4U.com Rev. 5.0, 09/03, page 333 of 806

A Tnop cycle, in which no operation is performed, is inserted before the Tc cycle in which the READ command is issued in figure 11.20, but when synchronous DRAM is read, there is a twocycle latency for the DQMxx signal that performs the byte specification. If the Tc cycle were performed immediately, without inserting a Tnop cycle, it would not be possible to perform the DQMxx signal specification for Td1 cycle data output. This is the reason for inserting the Tnop cycle. If the CAS latency is two cycles or longer, Tnop cycle insertion is not performed, since the timing requirements will be met even if the DQMxx signal is set after the Tc cycle.

When bank active mode is set, if only accesses to the respective banks in the area 3 space are considered, as long as accesses to the same row address continue, the operation starts with the cycle in figure 11.19 or 11.22, followed by repetition of the cycle in figure 11.20 or 11.23. An access to a different area 3 space during this time has no effect. If there is an access to a different row address in the bank active state, after this is detected the bus cycle in figure 11.21 or 11.24 is executed instead of that in figure 11.20 or 11.23. In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration.

The bank active mode should not be used unless the bus width for all areas is 32 bits.

Refreshing: The bus state controller is provided with a function for controlling synchronous DRAM refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in MCR. If synchronous DRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

• Auto-Refreshing 4U.com

Refreshing is performed at intervals determined by the input clock selected by bits CKS2-0 in RTCSR, and the value set in RTCOR. The value of bits CKS2-0 in RTCOR should be set so as to satisfy the refresh interval stipulation for the synchronous DRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in MCR, then make the CKS2-CKS0 setting. When the clock is selected by CKS2-CKS0, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed. At the same time, RTCNT is cleared to zero and the count-up is restarted. Figure 11.26 shows the auto-refresh cycle timing.

All-bank precharging is performed in the Tp cycle, then an REF command is issued in the TRr cycle following the interval specified by the TPC bits in MCR. After the TRr cycle, new command output cannot be performed for the duration of the number of cycles specified by the TRAS bits in MCR plus the number of cycles specified by the TPC bits in MCR. The TRAS and TPC bits must be set so as to satisfy the synchronous DRAM refresh cycle time stipulation (active/active command delay time).

Auto-refreshing is performed in normal operation, in sleep mode, and in case of a manual reset.

RENESAS

Figure 11.25 Auto-Refresh Operation www.DataSheet4U.com Rev. 5.0, 09/03, page 341 of 806

Figure 11.26 Synchronous DRAM Auto-Refresh Timing

• Self-Refreshing

Self-refresh mode is a kind of standby mode in which the refresh timing and refresh addresses are generated within the synchronous DRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit to 1. The self-refresh state is maintained while the CKE signal is low. Synchronous DRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the TPC bits in MCR. Self-refresh timing is shown in figure 11.27. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, or when exiting standby mode other than through a power-on reset, auto-refreshing is restarted if RFSH is set to 1 and RMODE is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately.

After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the SH7729R's standby function, and is maintained even after recovery from standby mode other than through a power-on reset. In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared.

Self-refreshing is performed in normal operation, in sleep mode, in standby mode, and in case of a manual reset.

When using synchronous DRAM, use the following procedure to initiate self-refreshing.

- 1. Clear the refresh control bit to 0.
- 2. Write H'00 to the RTCNT register.
- 3. Set the refresh control bit and refresh mode bit to 1.

Figure 11.27 Synchronous DRAM Self-Refresh Timing

• Relationship between Refresh Requests and Bus Cycle Requests

If a refresh request is generated during execution of a bus cycle, execution of the refresh is deferred until the bus cycle is completed. If a refresh request occurs when the bus has been released by the bus arbiter, refresh execution is deferred until the bus is acquired. If a match between RTCNT and RTCOR occurs while a refresh is waiting to be executed, so that a new refresh request is generated, the previous refresh request is eliminated. In order for refreshing to be performed normally, care must be taken to ensure that no bus cycle or bus mastership occurs that is longer than the refresh interval. When a refresh request is generated, the IRQOUT pin is asserted (driven low). Therefore, normal refreshing can be performed by having the IRQOUT pin monitored by a bus master other than the SH7729R requesting the bus, or the bus arbiter, and returning the bus to the SH7729R. When refreshing is started, and if no other interrupt request has been generated, the IRQOUT pin is negated (driven high).

www.DataSheet4U.com

Power-On Sequence: In order to use synchronous DRAM, mode setting must first be performed after powering on. To perform synchronous DRAM initialization correctly, the bus state controller registers must first be set, followed by a write to the synchronous DRAM mode register. In synchronous DRAM mode register setting, the address signal value at that time is latched by a combination of the RAS, CAS, and RD/WR signals. If the value to be set is X, the bus state controller provides for value X to be written to the synchronous DRAM mode register by performing a write to address H'FFFFD000 + X for area 2 synchronous DRAM, and to address H'FFFFE000 + X for area 3 synchronous DRAM. In this operation the data is ignored, but the mode write is performed as a byte-size access. To set burst read/single write, CAS latency 1 to 3, wrap type = sequential, and burst length 1 supported by the SH7729R, arbitrary data is written in a byte-size access.

With 32-bit bus width:

| | Area 2 | Area 3 |
|------------------------|----------|----------|
| CAS latency 1 | FFFFD840 | FFFFE840 |
| CAS latency 2 | FFFFD880 | FFFFE880 |
| CAS latency 3 | FFFFD8C0 | FFFFE8C0 |
| With 16-bit bus width: | | |
| | Area 2 | Area 3 |
| CAS latency 1 | FFFFD420 | FFFFE420 |
| CAS latency 2 | FFFFD440 | FFFFE440 |
| CAS latency 3 | FFFFD460 | FFFFE460 |
| | | |

Mode register setting timing is shown in figure 11.28.

As a result of the write to address H'FFFFD000 + X or H'FFFFE000 + X, a precharge all banks (PALL) command is first issued in the TRp1 cycle, then a mode register write command is issued in the TMw1 cycle.

Address signals, when the mode-register write command is issued, are as follows:

32-bit bus width:

A15-A9 = 0000100 (burst read and single write) A8-A6 = CAS latency A5 = 0 (burst type = sequential) A4-A2 = 000 (burst length 1)

16-bit bus width:

A14-A8 = 0000100 (burst read and single write) A7-A5 = CAS latency A4 = 0 (burst type = sequential) A3-A1 = 000 (burst length 1)

Before mode register setting, a 100 µs idle time (depending on the memory manufacturer) must be guaranteed after powering on requested by the synchronous DRAM. If the reset signal pulse width is greater than this idle time, there is no problem in performing mode register setting immediately. The number of dummy auto-refresh cycles specified by the manufacturer (usually 8) or more must be executed. This is usually achieved automatically while various kinds of initialization are being performed after auto-refresh setting, but a way of carrying this out more dependably is to set a short refresh request generation interval just while these dummy cycles are being executed. With simple read or write access, the address counter in the synchronous DRAM used for auto-refreshing is not initialized, and so the cycle must always be an auto-refresh cycle.

Figure 11.28 Synchronous DRAM Mode Write Timing

11.3.5 Burst ROM Interface

Setting bits A0BST1–0, A5BST1–0, and A6BST1–0 in BCR1 to a non-zero value allows burst ROM to be connected to areas 0, 5, and 6. The burst ROM interface provides high-speed access to ROM that has a nibble access function. The timing for nibble access to burst ROM is shown in figure 11.29. Two wait cycles are set. Basically, access is performed in the same way as for normal space, but when the first cycle ends the $\overline{CS0}$ signal is not negated, and only the address is changed before the next access is executed. When 8-bit ROM is connected, the number of consecutive accesses can be set as 4, 8, or 16 by bits A0BST1–0, A5BST1–0, or A6BST1–0. When 16-bit ROM is connected, 4 or 8 can be set in the same way. When 32-bit ROM is connected, only 4 can be set.

 $\overline{\text{WAIT}}$ pin sampling is performed in the first access if one or more wait states are set, and is always performed in the second and subsequent accesses.

The second and subsequent access cycles also comprise two cycles when a burst ROM setting is made and the wait specification is 0. The timing in this case is shown in figure 11.30.

Figure 11.29 Burst ROM Wait Access Timing

11.3.6 PCMCIA Interface

In the SH7729R, setting the A5PCM bit in BCR1 to 1 makes the bus interface for physical space area 5 an IC memory card and I/O card interface as stipulated in JEIDA version 4.2 (PCMCIA2.1). Setting the A6PCM bit to 1 makes the bus interface for physical space area 6 an IC memory card and I/O card interface as stipulated in JEIDA version 4.2.

When the PCMCIA interface is used, a bus size of 8 or 16 bits can be set by bits A5SZ1 and A5SZ0, or A6SZ1 and A6SZ0, in BCR2.

Figure 11.31 shows an example of PCMCIA card connection to the SH7729R. To enable active insertion of the PCMCIA cards (i.e. insertion or removal while system power is being supplied), a 3-state buffer must be connected between the SH7729R's bus interface and the PCMCIA cards.

As operation in big-endian mode is not explicitly stipulated in the JEIDA/PCMCIA specifications, the PCMCIA interface for the SH7729R in big-endian mode is stipulated independently.

However, the \overline{WAIT} signal is ignored in the following three cases:

- A write to external address space in dual address mode with 16-byte DMA transfer
- Transfer from an external device with DACK to external address space in single address mode with 16-byte DMA transfer
- Cache write-back access

www.DataSheet4U.com

Figure 11.31 Example of PCMCIA Interface

Renesas

Memory Card Interface Basic Timing: Figure 11.32 shows the basic timing for the PCMCIA IC memory card interface. When physical space areas 5 and 6 are designated as PCMCIA interface areas, bus accesses are automatically performed as IC memory card interface accesses.

With a high external bus frequency (CKIO), the setup and hold times for the address (A24–A0), card enable ($\overline{CS5}$, $\overline{CE2A}$, $\overline{CS6}$, $\overline{CE2B}$), and write data (D15–D0) in a write cycle, become insufficient with respect to \overline{RD} and \overline{WR} (the \overline{WE} pin in the SH7729R). The SH7729R provides for this by enabling setup and hold times to be set for physical space areas 5 and 6 in the PCR register. Also, software waits by means of a WCR2 register setting and hardware waits by means of the WAIT pin can be inserted in the same way as for the basic interface. Figure 11.33 shows the PCMCIA memory bus wait timing.

Figure 11.32 Basic Timing for PCMCIA Memory Card Interface

Figure 11.33 Wait Timing for PCMCIA Memory Card Interface

Memory Card Interface Burst Timing: In the SH7729R, when the IC memory card interface is selected, page mode burst access mode can be used, for read access only, by setting bits A5BST1 and A5BST0 in BCR1 for physical space area 5, or bits A6BST1 and A6BST0 in BCR1 for area 6. This burst access mode is not stipulated in JEIDA version 4.2 (PCMCIA2.1), but allows high-speed data access using ROM provided with a burst mode, etc.

Burst access mode timing is shown in figures 11.34 and 11.35.

Figure 11.34 Basic Timing for PCMCIA Memory Card Interface Burst Access

Renesas

Figure 11.35 Wait Timing for PCMCIA Memory Card Interface Burst Access

www.DataSheet4U.com

When the entire 32-Mbyte memory space is used as IC memory card interface space, the common memory/attribute memory switching signal $\overline{\text{REG}}$ is generated using a port, etc. If 16 Mbytes or less of memory space is sufficient, using 16 Mbytes of memory space as common memory space and 16 Mbytes as attribute memory space enables the A24 pin to be used for the $\overline{\text{REG}}$ signal.

Figure 11.36 PCMCIA Space Allocation

I/O Card Interface Timing: Figures 11.37 and 11.38 show the timing for the PCMCIA I/O card interface.

Switching between the I/O card interface and the IC memory card interface is performed according to the accessed address. When PCMCIA is designed for physical space area 5, the bus access is automatically performed as an I/O card interface access when a physical address from H'16000000 to H'17FFFFFF is accessed. When PCMCIA is designated for physical space area 6, the bus access is automatically performed as an I/O card interface access when a physical address from H'16000000 to H'17FFFFFF is accessed. When PCMCIA is designated for physical space area 6, the bus access is automatically performed as an I/O card interface access when a physical address from H'1A000000 to H'18FFFFFF is accessed.

When accessing a PCMCIA I/O card, the access should be performed using a non-cacheable area in virtual space (P2 or P3 space) or an area specified as non-cacheable by the MMU.

When an I/O card interface access is made to a PCMCIA card in little-endian mode, dynamic sizing of the I/O bus width is possible using the $\overline{IOIS16}$ pin. When a 16-bit bus width is set for area 5 or area 6, if the $\overline{IOIS16}$ signal is high during a word-size I/O bus cycle, the I/O port is recognized as being 8 bits in width. In this case, a data access for only 8 bits is performed in the I/O bus cycle being executed, followed automatically by a data access for the remaining 8 bits.

Figure 11.39 shows the basic timing for dynamic bus sizing.

In big-endian mode, the $\overline{IOIS16}$ signal is not supported, and should be fixed low.

Figure 11.39 Dynamic Bus Sizing Timing for PCMCIA I/O Card Interface

11.3.7 Waits between Access Cycles

A problem associated with higher external memory bus operating frequencies is that data buffer turn-off on completion of a read from a low-speed device may be too slow, causing a collision with data in the next access. This results in lower reliability or incorrect operation. To avoid this problem, a data collision prevention feature has been provided. This memorizes the preceding access area and the kind of read/write. If there is a possibility of a bus collision when the next access is started, a wait cycle is inserted before the access cycle thus preventing a data collision. There are two cases in which a wait cycle is inserted: when an access is followed by an access to a different area, and when a read access is followed by a write access from the SH7729R. When the SH7729R performs consecutive write cycles, the data transfer direction is fixed (from the SH7729R to other memory) and there is no problem. With read accesses to the same area, in principle, data is output from the same data buffer, and wait cycle insertion is not performed. Bits AnIW1 and AnIW0 (n = 0, 2-6) in WCR1 specify the number of idle cycles to be inserted between access cycles when a physical space area access is followed by an access to another area, or when the SH7729R performs a write access after a read access to physical space area n. If there is originally space between accesses, the number of idle cycles inserted is the specified number of idle cycles minus the number of empty cycles.

Waits are not inserted between accesses when bus arbitration is performed, since empty cycles are inserted for arbitration purposes.

Figure 11.40 Waits between Access Cycles

11.3.8 Bus Arbitration

When a bus release request (\overline{BREQ}) is received from an external device, buses are released after the bus cycle being executed is completed and a bus grant signal (\overline{BACK}) is output. The bus is not released during burst transfers for cache fills or TAS instruction execution between the read cycle and write cycle. Bus arbitration is not executed in multiple bus cycles that are generated when the data bus width is shorter than the access size; i.e. in the bus cycles when longword access is executed for the 8-bit memory. At the negation of \overline{BREQ} , \overline{BACK} is negated and bus use is restarted. See Appendix A.1, Pin States, for the pin states when the bus is released.

The SH7729R sometimes needs to retrieve a bus it has released. For example, when memory generates a refresh request or an interrupt request internally, the SH7729R must perform the appropriate processing. The SH7729R has a bus request signal (\overline{IRQOUT}) for this purpose. When it must retrieve the bus, it asserts the \overline{IRQOUT} signal. Devices asserting an external bus release request receive the assertion of the \overline{IRQOUT} signal and negate the \overline{BREQ} signal to release the bus. The SH7729R retrieves the bus and carries out the processing.

www.DataSheet4U.com Rev. 5.0, 09/03, page 363 of 806

Renesas

IRQOUT Pin Assertion Conditions:

- When a memory refresh request has been generated but the refresh cycle has not yet begun
- When an interrupt is generated with an interrupt request level higher than the setting of the interrupt mask bits (I3–I0) in the status register (SR). (This does not depend on the SR.BL bit.)

11.3.9 Bus Pull-Up

With the SH7729R, address pin pull-up can be performed when the bus is released by setting the PULA bit in BCR1 to 1. The address pins are pulled up for a 4-clock period after \overline{BACK} is asserted. Figure 11.41 shows the address pin pull-up timing. Similarly, data pin pull-up can be performed by setting the PULD bit in BCR1 to 1. The data pins should be pulled up when the data bus is not in use. The data pin pull-up timing for a read cycle is shown in figure 11.42, and the timing for a write cycle in figure 11.43.

11.3.10 MCS[0] to MCS[7] Pin Control

The SH7729R is provided with pins $\overline{\text{MCS}[0]} - \overline{\text{MCS}[7]}$ as dedicated $\overline{\text{CS}}$ pins for the ROM connected to area 0 or 2. Assertion of $\overline{\text{MCS}[0]} - \overline{\text{MCS}[7]}$ is controlled by settings in MCSCR0–MCSCR7. This enables 32-, 64-, 128-, or 256-Mbit memory to be connected to area 0 or area 2. However, only CS2/0 = 0 (area 0) should be used for MCSCR0. Table 11.15 shows MCSCR0–MCSCR7 settings and $\overline{\text{MCS}[0]} - \overline{\text{MCS}[7]}$ assertion conditions.

As the $\overline{\text{MCS}[0]}$ - $\overline{\text{MCS}[7]}$ pins are multiplexed as the PTC0-PTC7 pins, when using these pins as $\overline{\text{MCS}[0]}$ - $\overline{\text{MCS}[7]}$, the corresponding bits in the PCCR register should be set to "other function."

When CS2/0 = 0 in the MCSCR0 and when the PTC0 pin is switched to $\overline{MCS[0]}$ (when PCOMD1–PCOMD0 are set to "other function"), the $\overline{CS0}$ pin is also switched to $\overline{MCS[0]}$.

As port register writes operate on the peripheral clock, they take time compared with instruction execution by the CPU operating on the high-speed internal clock. Therefore, if an instruction that accesses $\overline{MCS[1]}$ to $\overline{MCS[7]}$ is located several instructions after an instruction that switches port C to \overline{MCS} , the switch from PTC[n] to \overline{MCSn} and from $\overline{CS0}$ to $\overline{MCS[0]}$ may not be performed correctly.

To prevent this problem, the following switching procedure should be used.

- When the program runs with cache on
- (1) To switch port C to $\overline{\text{MCS}}$, set the corresponding bits in the PCCR register to 00 ("other function").
- (2) Read the PCCR register and check whether the set value is read. Repeat until the set value is read.
- (3) Perform a dummy read from non-cacheable CS0 space (e.g. address H'A0000000). This will result in an access to the CS0 space, and immediately afterward, CS0 will be switched to MCS[0], and port C[n] will be switched to MCS[n].
- (4) Access can now be made to the $\overline{MCS[1]}$ to $\overline{MCS[7]}$ spaces.
- When the program runs in MCS[0] space with cache off
- (1) Set the PCCR register as in (1) above.
- (2) Place at least three NOP instructions after the instruction in (1). As a result, when the PCCR register is rewritten, an access to the CS0 space will be generated, and immediately afterward, CS0 will be switched to MCS[0], and port C[n] will be switched to MCS[n].
- (3) Access can now be made to the $\overline{\text{MCS}[1]}$ to $\overline{\text{MCS}[7]}$ spaces.

Section 12 Direct Memory Access Controller (DMAC)

12.1 Overview

The SH7729R includes a four-channel direct memory access controller (DMAC). The DMAC can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, memory-mapped external devices, and on-chip peripheral modules (IrDA, SCIF, A/D converter, and D/A converter). Using the DMAC reduces the burden on the CPU and increases overall operating efficiency.

12.1.1 Features

The DMAC has the following features.

- Four channels
- 4-GB physical address space
- 8-bit, 16-bit, 32-bit, or 16-byte transfer (In 16-byte transfer, four 32-bit reads are executed, followed by four 32-bit writes.)
- 16 Mbytes (16,777,216 transfers)
- Address mode: Dual address mode and single address mode are supported. In addition, direct address transfer mode or indirect address transfer mode can be selected.
 - Dual address mode transfer: Both the transfer source and transfer destination are accessed by address. Dual address mode has direct address transfer mode and indirect address transfer mode.

Direct address transfer mode: The values specified in the DMAC registers indicates the transfer source and transfer destination. Two bus cycles are required for one data transfer. Indirect address transfer mode: Data is transferred with the address stored prior to the address specified in the transfer source address in the DMAC. Other operations are the same as those of direct address transfer mode. This function is only available in channel 3. Four bus cycles are required for one data transfer.

- Single address mode transfer: Either the transfer source or transfer destination peripheral device is accessed (selected) by means of the DACK signal, and the other device is accessed by address. One transfer unit of data is transferred in one bus cycle.
- Channel functions: The transfer mode that can be specified depends on the channel:
 - Channel 0: External request can be accepted.
 - Channel 1: External request can be accepted.
 - Channel 2: This channel has a source address reload function, which reloads a source address every four transfers.
 - Channel 3: In this channel, direct address mode or indirect address transfer mode can be specified.

www.DataSheet4U.com Rev. 5.0, 09/03, page 369 of 806

- Reload function: The value that was specified in the source address register can be automatically reloaded every four DMA transfers. This function is only available in channel 2.
- Transfer requests
 - External request (From two DREQ pins (channels 0 and 1 only). DREQ can be detected either by edge or by level.)
 - On-chip module request (Requests from on-chip peripheral modules such as serial communications interface (IrDA and SCIF), A/D converter (A/D) and a timer (CMT). This request can be accepted in all the channels.)
 - Auto request (The transfer request is generated automatically within the DMAC.)
- Selectable bus modes: Cycle-steal mode or burst mode
- Selectable channel priority levels:

Fixed mode: The channel priority is fixed.

Round-robin mode: The priority of the channel in which the execution request was accepted is made the lowest.

• Interrupt request: An interrupt request to the CPU can be generated after the specified number of transfers.

12.1.2 Block Diagram

Figure 12.1 shows a block diagram of the DMAC.

Figure 12.1 Block Diagram of DMAC

12.1.3 Pin Configuration

Table 12.1 shows the DMAC pins.

Table 12.1 DMAC Pins

| ChannelwwNameheet4U.com | | Symbol | I/O | Function |
|-------------------------|----------------------------|--------|-----|--|
| 0 | DMA transfer request | DREQ0 | I | DMA transfer request input from external device to channel 0 |
| | DREQ acknowledge | DACK0 | 0 | Strobe output to an external I/O upon DMA transfer request from external device to channel 0 |
| | DMA request acknowledge | DRAK0 | 0 | Output showing that DREQ0 has been accepted |
| 1 | DMA transfer request | DREQ1 | I | DMA transfer request input from external device to channel 1 |
| | DREQ acknowledge | DACK1 | 0 | Strobe output to an external I/O upon DMA transfer request from external device to channel 1 |
| | DMA request acknowledge | DRAK1 | 0 | Output showing that DREQ1 has been accepted |

12.1.4 Register Configuration

Table 12.2 summarizes the DMAC registers. The DMAC has a total of 17 registers: four control registers for each other control register shared by all channels.

Table 12.2DMAC Registers

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

1. Only 0 can be written to bit 1 of CHCR0 to CHCR3, and bits 1 and 2 of DMAOR to clear the flag after 1 is read.

2. If 16-bit access is used on SAR0 to SAR3, DAR0 to DAR3, and CHCR0 to CHCR3, the value in the 16 bits that were not accessed is retained.

3. DMATCR comprises the 24 bits from bit 0 to bit 23. The upper 8 bits, bits 24 to 31, cannot be written with 1 and are always read as 0.

4. When address translation by the MMU does not apply, the address in parentheses should be used.

www.DataSheet4U.com

12.2 Register Descriptions

12.2.1 DMA Source Address Registers 0–3 (SAR0–SAR3)

DMA source address registers 0–3 (SAR0–SAR3) are 32-bit readable/writable registers that specify the source address of a DMA transfer. During a DMA transfer, these registers indicate the next source address.

To transfer data in 16 bits or in 32 bits, specify a 16-bit or 32-bit address boundary address. When transferring data in 16-byte units, a 16-byte boundary (address 16n) must be set for the source address value. Operation is not guaranteed if other addresses are specified.

Bit: 31 30 29 28 27 26 25 24 Initial value: ____ ____ _ ____ ____ ____ ____ R/W: R/W R/W R/W R/W R/W R/W R/W R/W Bit: 22 23 21 20 0 Initial value: ____ . . . R/W: R/W R/W R/W R/W R/W . . .

The initial value is undefined in a reset. The previous value is retained in standby mode.

12.2.2 DMA Destination Address Registers 0–3 (DAR0–DAR3)

DMA destination address registers 0–3 (DAR0–DAR3) are 32-bit readable/writable registers that specify the destination address of a DMA transfer. These registers include a count function, and during a DMA transfer, these registers indicate the next destination address.

To transfer data in 16 bits or in 32 bits, specify a 16-bit or 32-bit address boundary address. To transfer data in 16-bit or 32-bit units, make sure to specify a destination address with a 16-byte boundary (16n address). Operation is not guaranteed if other addresses are specified.

The initial value is undefined in a reset. The previous value is retained in standby mode.

12.2.3 DMA Transfer Count Registers 0–3 (DMATCR0–DMATCR3)

DMA transfer count registers 0–3 (DMATCR0–DMATCR3) are 24-bit readable/writable registers that specify the DMA transfer count (bytes, words, or longwords). The number of transfers is 1 when the setting is H'000001, and 16,777,216 (the maximum) when H'000000 is set. During a DMA transfer, these registers indicate the remaining number of transfers.

In 16-byte transfer, one 16-byte transfer (128 bits) is counted as one.

Writing to upper eight bits in DMATCR is invalid; 0s are read if these bits are read.

When using 16-byte transfer, an integral multiple of 4 (4n) must be set for the number of transfers to ensure normal operation.

The initial value is undefined in a reset. The previous value is retained in standby mode.

Renesas

12.2.4 DMA Channel Control Registers 0–3 (CHCR0–CHCR3)

DMA channel control registers 0–3 (CHCR0–CHCR3) are 32-bit readable/writable registers that specify the operation mode, transfer method, etc., for each channel. Writing to bits 31 to 21 and 7 in this register is invalid; 0s are read if these bits are read.

Bit 20 is only used in CHCR3; it is not used in CHCR0 to CHCR2. Consequently, writing to this bit is invalid in CHCR0 to CHCR2; 0 is read if this bit is read. Bit 19 is only used in CHCR2; it is not used in CHCR0, CHCR1, and CHCR3. Consequently, writing to this bit is invalid in CHCR0, CHCR1, and CHCR3; 0 is read if this bit is read. Bits 6 and 16 to 18 are only used in CHCR0 and CHCR1; they are not used in CHCR2 and CHCR3. Consequently, writing to these bits is invalid in CHCR0 and CHCR1; they are not used in CHCR2 and CHCR3. Consequently, writing to these bits is invalid in CHCR0 and CHCR1; they are not used in CHCR2 and CHCR3. Consequently, writing to these bits is invalid in CHCR2 and CHCR3.

These register values are initialized to zero in a power-on reset. The previous value is retained in standby mode.

Notes: 1. Only 0 can be written to the TE bit after 1 is read.

2. The DI, RO, RL, AM, AL, and DS bits are not included in some channels.

Bits 31 to 21, 7—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 20—Direct/Indirect Selection (DI): Selects direct address mode or indirect address mode in channel 3.

This bit is only valid in CHCR3. Writing to this bit is invalid in CHCR0 to CHCR2; 0 is read if this bit is read. When using 16-byte transfer, direct address mode must be specified. Operation is not guaranteed if indirect address mode is specified.

| Bit 20: DI | Description | |
|------------|-----------------------|-----------------|
| 0 | Direct address mode | (Initial value) |
| 1 | Indirect address mode | |

Bit 19—Source Address Reload Bit (RO): Selects whether the source address initial value is reloaded in channel 2.

This bit is only valid in CHCR2. Writing to this bit is invalid in CHCR0, CHCR1, and CHCR3; 0 is read if this bit is read. When using 16-byte transfer, this bit must be cleared to 0, specifying non-reloading. Operation is not guaranteed if reloading is specified.

| Bit 19: RO | Description | |
|------------|--------------------------------|-----------------|
| 0 | Source address is not reloaded | (Initial value) |
| 1 | Source address is reloaded | |

Bit 18—Request Check Level Bit (RL): Specifies whether DRAK (DREQ acknowledge) signal output is active-high or active-low.

This bit is only valid in CHCR0 and CHCR1. Writing to this bit is invalid in CHCR2 and CHCR3; 0 is read if this bit is read.

| Bit 18: RL | Description | |
|------------|-------------------------|-----------------|
| 0 | Active-low DRAK output | (Initial value) |
| 1 | Active-high DRAK output | |

Bit 17—Acknowledge Mode Bit (AM): Specifies whether DACK is output in the data read cycle or in the data write cycle in dual address mode.

This bit is only valid in CHCR0 and CHCR1. Writing to this bit is invalid in CHCR2 and CHCR3; 0 is read if this bit is read.

| Bit 17: AMw.DataSheet41 | Description | |
|-------------------------|----------------------------|-----------------|
| 0 | DACK output in read cycle | (Initial value) |
| 1 | DACK output in write cycle | |

Bit 16—Acknowledge Level (AL): Specifies whether DACK (acknowledge) signal output is active-high or active-low.

This bit is only valid in CHCR0 and CHCR1. Writing to this bit is invalid in CHCR2 and CHCR3; 0 is read if this bit is read.

| Bit 16: AL | Description | |
|------------|-------------------------|-----------------|
| 0 | Active-low DACK output | (Initial value) |
| 1 | Active-high DACK output | |

Bits 15 and 14—Destination Address Mode Bits 1 and 0 (DM1, DM0): Select whether the DMA destination address is incremented, decremented, or left fixed.

| Bit 15: DM1 | Bit 14: DM0 | Description | |
|-------------|-------------|--|-----------------|
| 0 | 0 | Fixed destination address* | (Initial value) |
| 0 | 1 | Destination address is incremented (+1 in 8-bit 16-bit transfer, +4 in 32-bit transfer, +16 in 16-b | , |
| 1 | 0 | Destination address is decremented (–1 in 8-bit 16-bit transfer, –4 in 32-bit transfer; illegal settir transfer) | |
| 1 | 1 | Setting prohibited | |

Note: * This setting cannot be used when the transfer destination is X/Y memory in 16-byte transfer.

| Bit 13: SM1 | Bit 12: SM0 | Description |
|--------------|--------------------------|---|
| 0 | 0 | Fixed source address* (Initial value |
| 0 www.Dat | 1 aSheet4U.com | Source address is incremented (+1 in 8-bit transfer, +2 in 16- bit transfer, +4 in 32-bit transfer, +16 in 16-byte transfer) |
| 1 | 0 | Source address is decremented (-1 in 8-bit transfer, -2 in 16 bit transfer, -4 in 32-bit transfer; illegal setting in 16-byte transfer) |
| 1 | 1 | Setting prohibited |

Bits 13 and 12—Source Address Mode Bits 1 and 0 (SM1, SM0): Select whether the DMA source address is incremented, decremented, or left fixed.

Note: * This setting cannot be used when the transfer destination is X/Y memory in 16-byte transfer.

If the transfer source is specified by indirect address, specify the address holding the value of the address in which the data to be transferred is stored (i.e. the indirect address) in source address register 3 (SAR3).

Specification of SAR3 incrementing or decrementing in indirect address mode depends on the SM1 and SM0 settings. In this case, however, the SAR3 increment or decrement value is +4, -4, or fixed at 0, regardless of the transfer data size specified in TS1 and TS0.

| Bit 11: RS3 | Bit 10: RS2 | Bit 9: RS1 | Bit 8: RS0 | Description |

| 0 | 1 | 1 | 1 | Setting prohibited |
| 1 | 0 | 0 | 0 | Setting prohibited |
| 1 | 0 | 0 | 1 | Setting prohibited |
| 1 | 0 | 1 | 0 | IrDA transmission |
| 1 | 0 | 1 | 1 | IrDA reception |
| 1 | 1 | 0 | 0 | SCIF transmission |
| 1 | 1 | 0 | 1 | SCIF reception |
| 1 | 1 | 1 | 0 | Internal A/D |
| 1 | 1 | 1 | 1 | CMT |

Bits 11 to 8—Resource Select Bits 3 to 0 (RS3 to RS0): Specify which transfer requests will be sent to the DMAC.

Notes: When using 16-byte transfer, the following settings must not be made:

1010 IrDA transmission

- 1011 IrDA reception
- 1100 SCIF transmission
- 1101 SCIF reception
- 1110 A/D converter
- 1111 CMT

Operation is not guaranteed if these settings are made.

* External request specification is valid only in channels 0 and 1. None of the request sources can be selected in channels 2 and 3.

Bit 6—DREQ Select Bit (DS): Selects low-level or falling-edge detection as the sampling method for the DREQ pin used in external request mode.

This bit is only valid in CHCR0 and CHCR1. Writing to this bit is invalid in CHCR2 and CHCR3; 0 is read if this bit is read.

In channels 0 and 1, if an on-chip peripheral module is specified as a transfer request source or an auto-request is specified, the specification of this bit is ignored and falling-edge detection is fixed except in an auto-request.

| Bit 6: DS | Description | |
|-----------|-------------------------------|-----------------|
| 0 | DREQ detected by low level | (Initial value) |
| 1 | DREQ detected at falling edge | |

Bit 5—Transmit Mode (TM): Specifies the bus mode when transferring data.

| Bit 5: TM | Description | |
|-----------|------------------|-----------------|
| 0 | Cycle-steal mode | (Initial value) |
| 1 | Burst mode | |

Bits 4 and 3—Transmit Size Bits 1 and 0 (TS1, TS0): Specify the size of data to be transferred.

| Bit 4: TS1 | Bit 3: TS0 | Description | |
|------------|------------|-------------------------------------|-----------------|
| 0 | 0 | Byte size (8 bits) | (Initial value) |
| 0 | 1 | Word size (16 bits) | |
| 1 | 0 | Longword size (32 bits) | |
| 1 | 1 | 16-byte unit (4 longword transfers) | |

Bit 2—Interrupt Enable Bit (IE): If this bit is set to 1, an interrupt is requested on completion of the number of data transfers specified in DMATCR (i.e. when TE = 1).

| Bit 2: IE | Description | |
|-----------|---|---------------------------|
| 0 | Interrupt request is not generated on completion of data tra specified in DMATCR | nsfers (Initial value) |
| 1 | Interrupt request is generated on completion of data transfe DMATCR | ers specified in |

Bit 1—Transfer End Bit (TE): Set to 1 on completion of the number of data transfers specified in DMATCR. At this time, if the IE bit is set to 1, an interrupt request is generated.

If data transfer ends due to an NMI interrupt, a DMAC address error, or clearing of the DE bit or the DME bit in DMAOR before this bit is set to 1, this bit will not be set to 1. Even if the DE bit is set to 1 while this bit is set to 1, transfer is not enabled.

www.DataSheet4U.com

| Bit 1: TE | Description | | |
|-----------|---|--|--|
| 0 | Data transfers specified in DMATCR not completed (Initial val | | |
| | Clearing conditions: Writing 0 to TE after reading TE = 1 | | |
| | Power-on reset, manual reset | | |
| 1 | Data transfers specified in DMATCR completed | | |

Bit 0—DMAC Enable Bit (DE): Enables operation of the corresponding channel.

| Bit 0: DE | Description | |
|-----------|----------------------------|-----------------|
| 0 | Channel operation disabled | (Initial value) |
| 1 | Channel operation enabled | |

If an auto-request is specified (RS3 to RS0), transfer starts when this bit is set to 1. In an external request or an internal module request, transfer starts when a transfer request is generated after this bit is set to 1. Clearing this bit during transfer terminates the transfer.

Even if the DE bit is set, transfer is not enabled if the TE bit is 1, the DME bit in DMAOR is 0, or the NMIF bit in DMAOR is 1.

12.2.5 DMA Operation Register (DMAOR)

The DMA operation register (DMAOR) is a 16-bit readable/writable register that controls the DMAC transfer mode. Writing to bits 15 to 10 and bits 7 to 3 is invalid in this register; 0 is always read if these bits are read.

DMAOR is initialized to 0 by a power-on reset, and in hardware standby mode or software standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|----|----|----|----|----|--------|--------|-----|
| | _ | — | — | — | — | — | PR1 | PR0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R/W | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | — | _ | — | — | AE | NMIF | DME |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/(W)* | R/(W)* | R/W |
| | | | | | | | | |

Note: * Only 0 can be written to the AE and NMIF bits after 1 is read.

Bits 15 to 10—Reserved: These bits are always read as 0. The write value should always be 0.

Bits 9 and 8—Priority Mode Bits 1 and 0 (PR1, PR0): Select the priority level between channels when there are simultaneous transfer requests for multiple channels.

| Bit 9: PR1 | Bit 8: PR0 | Description | |
|------------|------------|-----------------------|-----------------|
| 0 | 0 | CH0 > CH1 > CH2 > CH3 | (Initial value) |
| 0 | 1 | CH0 > CH2 > CH3 > CH1 | |
| 1 | 0 | CH2 > CH0 > CH1 > CH3 | |
| 1 | 1 | Round-robin | |

Bits 7 to 3—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 2—Address Error Flag Bit (AE): Indicates that an address error occurred during DMA transfer. If this bit is set during data transfer, transfers on all channels are suspended. The CPU cannot write 1 to this bit. This bit can only be cleared by writing 0 after reading 1.

| Bit 2: Al | Description | |
|-----------|---|-----------------|
| 0 | No DMAC address error; DMA transfer is enabled | (Initial value) |
| | ww.DataSheet4U.com Clearing conditions: Writing 0 to AE after reading AE = 1 | |
| | Power-on reset, manual reset | |
| 1 | DMAC address error; DMA transfer is disabled | |
| | This bit is set by occurrence of a DMAC address error | |

Bit 1—NMI Flag Bit (NMIF): Indicates that an NMI interrupt occurred. This bit is set regardless of whether the DMAC is in the operating or halted state. The CPU cannot write 1 to this bit. Only 0 can be written to clear this bit after 1 is read.

| Bit 1: NMIF | Description |
|-------------|---|
| 0 | No NMI input; DMA transfer is enabled (Initial value) |
| | Clearing conditions: Writing 0 to NMIF after reading NMIF = 1 |
| | Power-on reset, manual reset |
| 1 | NMI input; DMA transfer is disabled |
| | This bit is set by occurrence of an NMI interrupt |

Bit 0—DMA Master Enable Bit (DME): Enables or disables DMA transfers on all channels. If the DME bit and the DE bit corresponding to each channel in CHCR are set to 1, transfer is enabled on the corresponding channel. If this bit is cleared during transfer, transfer on all the channels will be terminated.

Even if the DME bit is set, transfer is not enabled if the TE bit is 1 or the DE bit is 0 in CHCR, or the NMIF bit is 1 in DMAOR.

| Bit 0: DME | Description | |
|------------|---------------------------------------|-----------------|
| 0 | DMA transfer disabled on all channels | (Initial value) |
| 1 | DMA transfer enabled on all channels | |

12.3 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto-request, external request, and on-chip module request. The dual address mode has direct address transfer mode and indirect address transfer mode. Burst mode or cycle-steal mode can be selected as the bus mode.

12.3.1 DMA Transfer Flow

After the DMA source address register (SAR), DMA destination address register (DAR), DMA transfer count register (DMATCR), DMA channel control register (CHCR), and DMA operation register (DMAOR) are set, the DMAC transfers data according to the following procedure:

- 1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, NMIF = 0)
- 2. When a transfer request comes and transfer is enabled, the DMAC transfers 1 transfer unit of data (according to the TS0 and TS1 settings). For an auto-request, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented for each transfer. The actual transfer flows vary by address mode and bus mode.
- 3. When the specified number of transfers have been completed (when DMATCR reaches 0), the transfer ends normally. If the IE bit in CHCR is set to 1 at this time, a DEI interrupt is sent to the CPU.
- 4. When an NMI interrupt is generated, the transfer is aborted. Transfers are also aborted when the DE bit in CHCR or the DME bit in DMAOR are changed to 0.

Figure 12.2 is a flowchart of this procedure.

DREQ = edge detection in burst mode (external request) or cycle-steal mode.
 DREQ = edge detection in burst mode (external request), or auto-request mode in burst mode.

Figure 12.2 DMAC Transfer Flowchart

12.3.2 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated by devices and on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in three modes: auto-request, external request, and on-chip module request. The request mode is selected in the RS3–RS0 bits of DMA channel control registers 0–3 (CHCR0–CHCR3).

Auto-Request Mode: When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, the auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bit of CHCR0–CHCR3 and the DME bit of DMAOR are set to 1, the transfer begins so long as the TE bit of CHCR0–CHCR3 and the NMIF bit of DMAOR are 0.

External Request Mode: In this mode a transfer is performed in response to the request signal (\overline{DREQ}) of an external device. Choose one of the modes shown in table 12.3 according to the application system. When this mode is selected, if DMA transfer is enabled (DE = 1, DME = 1, TE = 0, NMIF = 0), a transfer is performed upon a request at the \overline{DREQ} input. Choose \overline{DREQ} detection by either a falling edge or low level of the signal input with the DS bit in CHCR0 and CHCR1 (DS = 0 for level detection, DS = 1 for edge detection). The source of the transfer request does not have to be the data transfer source or destination.

| RS3 | RS2 | RS1 | RS0 | Address Mode | Source | Destination |
|-----|-----|-----|-----|----------------------|--|--|
| 0 | 0 | 0 | 0 | Dual address mode | Any* | Any* |
| | | 1 | 0 | Single address mode | External memory, memory-mapped external device | External device with DACK |
| | | | 1 | | External device with DACK | External memory, memory-mapped external device |

Table 12.3 Selecting External Request Modes with RS Bits

Note: * External memory, memory-mapped external device, on-chip memory, on-chip peripheral module (excluding DMAC, UBC, and BSC)

On-Chip Module Request: In this mode a transfer is performed in response to a transfer request signal (interrupt request signal) of an on-chip module. This mode cannot be set in case of 16-byte transfer. These are six transfer request signals: the receive-data-full interrupts (RXI) and the transmit-data-empty interrupts (TXI) from two serial communication interfaces (IrDA, SCIF), the A/D conversion end interrupt (ADI) of the A/D converter, and the compare match timer interrupt (CMI) of the CMT (table 12.4). When this mode is selected, if DMA transfer is enabled (DE = 1, DME = 1, TE = 0, NMIF = 0), a transfer is performed upon input of a transfer transfer.

Rev. 5.0, 09/03, page 389 of 806

source of the transfer request does not have to be the data transfer source or destination. When RXI is set as the transfer request, however, the transfer source must be the SCI's receive data register (RDR). Likewise, when TXI is set as the transfer request, the transfer source must be the SCI's transmit data register (TDR). If the transfer requester is the A/D converter, the data transfer source must be the A/D data register.

| RS3 | RS2 | RS1 | RS0 | DMA Transfer Request Source | DMA Transfer Request Signal | Source | Desti- nation | Bus Mode |
|-----|-----|-----|-----|--------------------------------------|--|--------|------------------|-----------------------|
| 1 | 0 | 1 | 0 | IrDA transmitter | TXI1 (IrDA transmit-data-empty interrupt transfer request) | Any* | TDR1 | Cycle-steal |
| 1 | 0 | 1 | 1 | IrDA receiver | RXI1 (IrDA receive-data-full interrupt transfer request) | RDR1 | Any* | Cycle-steal |
| 1 | 1 | 0 | 0 | SCIF transmitter | TXI2 (SCIF transmit-data-empty interrupt transfer request) | Any* | TDR2 | Cycle-steal |
| 1 | 1 | 0 | 1 | SCIF receiver | RXI2 (SCIF receive-data-full interrupt transfer request) | RDR1 | Any* | Cycle-steal |
| 1 | 1 | 1 | 0 | A/D converter | ADI (A/D conversion end interrupt) | ADDR | Any* | Cycle-steal |
| 1 | 1 | 1 | 1 | CMT | CMI (Compare match timer interrupt) | Any* | Any* | Burst/ cycle-steal |

ADDR: A/D data register of A/D converter

Note: * External memory, memory-mapped external device, on-chip peripheral module (excluding DMAC, BSC, UBC)

When outputting transfer requests from on-chip peripheral modules, the appropriate interrupt enable bits must be set to output the interrupt signals.

If the interrupt request signal of the on-chip peripheral module is used as a DMA transfer request signal, an interrupt is not sent to the CPU.

The DMA transfer request signals in table 12.4 are automatically discontinued when the corresponding DMA transfer is performed. If cycle-steal mode is being employed, they are withdrawn at the first transfer; if burst mode is being used, they are discontinued at the last transfer.

12.3.3 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it selects a channel according to a predetermined priority order. Two modes (fixed mode and round-robin mode) are selected by priority bits PR1 and PR0 in the DMA operation register (DMAOR).

Fixed Mode: In these modes, the priority order of the channels remain fixed. There are three kinds of fixed modes as follows:

 $\label{eq:CH0} \begin{array}{l} CH0 > CH1 > CH2 > CH3 \\ CH0 > CH2 > CH3 > CH1 \\ CH2 > CH0 > CH1 > CH3 \end{array}$

These are selected by the PR1 and PR0 bits in DMAOR.

Round-Robin Mode: Each time one word, byte, or longword is transferred on one channel, the priority order is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority order. The round-robin mode operation is shown in figure 12.3. The priority of the round-robin mode is CH0 > CH1 > CH2 > CH3 immediately after reset.

Figure 12.3 Round-Robin Mode

Figure 12.4 shows how the priority order changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

- 1. Transfer requests are generated simultaneously for channels 0 and 3.
- 2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).^{ataSheet4U.com}
- 3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
- 4. When the channel 0 transfer ends, channel 0 becomes lowest-priority.
- 5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
- 6. When the channel 1 transfer ends, channel 1 becomes lowest-priority.
- 7. The channel 3 transfer begins.
- 8. When the channel 3 transfer ends, channels 3 and 2 shift downward in priority so that channel 3 becomes the lowest-priority.

Figure 12.4 Changes in Channel Priority in Round-Robin Mode

12.3.4 DMA Transfer Types

The DMAC supports the transfers shown in table 12.5. In dual address mode, both the transfer source address and the transfer destination address are output. Dual address mode has a direct address mode and indirect address mode. In direct address mode, an output address value is the data transfer target address; in indirect address mode, the value stored in the output address, not the output address value itself, is the data transfer target address. Data transfer timing depends on the bus mode, which may be cycle-steal mode or burst mode.

Table 12.5 Supported DMA Transfers

Notes: 1. Dual: Dual address mode

2. Single: Single address mode

3. Dual address mode includes direct address mode and indirect address mode.

4. 16-byte transfer is not available for on-chip peripheral modules.

Address Modes:

Dual Address Mode

In dual address mode, both the transfer source and destination are accessed (selectable) by an address. The source and destination can be located externally or internally. Dual address mode has (1) a direct address transfer mode and (2) an indirect address transfer mode.

www.DataSheet4U.com

(1) In direct address transfer mode, DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in figure 12.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a write cycle. Figures 12.6 to 12.8 show examples of the timing at whis time.

Figure 12.5 Operation of Direct Address Mode in Dual Address Mode

Figure 12.7 Example of DMA Transfer Timing in the Direct Address Mode in Dual Mode (16-byte Transfer, Transfer Source: Ordinary Memory, Transfer Destination: Ordinary Memory)

Figure 12.8 Example of DMA Transfer Timing in the Direct Address Mode in Dual Mode (16-byte Transfer, Transfer Source: Synchronous DRAM, Transfer Destination: Ordinary Memory)

(2) In indirect address transfer mode, the address of memory in which data to be transferred is stored is specified in the transfer source address register (SAR3) in the DMAC. 16-byte transfer is not possible. Consequently, in this mode, the address value specified in the transfer source address register in the DMAC is read first. This value is temporarily stored in the DMAC. Next, the read value is output as an address, and the value stored in that address is stored in the DMAC again. Then, the value read afterwards is written to the address specified in the transfer destination address; this completes one DMA transfer.

Figure 12.9 shows an example. In this example, the transfer destination, the transfer source, and the storage destination of the indirect address are external memories, and transfer data is 16 or 8 bits. Figure 12.10 shows an example of the transfer timing.

In this mode, one NOP cycle (CK1 cycle shown in figure 12.10) is required to output data read as an indirect address to an address bus.

If transfer data is 32 bits, the third and fourth bus cycles shown in figure 12.10 are required twice for each; a total of six bus cycles and one NOP cycle are required.

When the value in SAR3 is an address, the memory data is read and the value is stored in the temporary buffer. The value to be read must be 32 bits since it is used for the address.

First and second bus cycles

When the value in the temporary buffer is an address, the data is read from the transfer source module to the data buffer.

Third bus cycle

When the value in DAR3 is an address, the value in the data buffer is written to the transfer source module.

Fourth bus cycle

Note: This example shows memory, the transfer source module, and the transfer destination module; in practice, any module can be connected in the addressing space.

Figure 12.9 Indirect Address Operation in Dual Address Mode (When External Memory Space has a 16-Bit Width)

Figure 12.10 Example of Transfer Timing in the Indirect Address Mode in Dual Address Mode

• Single Address Mode

In single address mode, either the transfer source or transfer destination peripheral device is accessed (selected) by means of the DACK signal, and the other device is accessed by address. In this mode, the DMAC performs one DMA transfer in one bus cycle, accessing one of the external devices by outputting the DACK transfer request acknowledge signal to it, and at the same time outputting an address to the other device involved in the transfer. For example, in the case of transfer between external memory and an external device with DACK shown in figure 12.11, when the external device outputs data to the data bus, that data is written to the external memory in the same bus cycle.

Figure 12.11 Data Flow in Single Address Mode

Two kinds of transfer are possible in single address mode: (1) transfer between an external device with DACK and a memory-mapped external device, and (2) transfer between an external device with DACK and external memory. In both cases, only the external request signal (DREQ) is used for transfer requests.

Figures 12.12 and 12.13 show examples of DMA transfer timing in single address mode.

www.DataSheet4U.com Rev. 5.0, 09/03, page 401 of 806

Figure 12.12 Example of DMA Transfer Timing in Single Address Mode

www.DataSheet4U.com

Figure 12.13 Example of DMA Transfer Timing in Single Address Mode (External Memory Space (Ordinary Memory) → External Device with DACK)

Bus Modes: There are two bus modes: cycle-steal and burst. Select the mode in the TM bits of CHCR0–CHCR3.

Cycle-Steal Mode

In cycle-steal mode, the bus is given to another bus master after a one-transfer-unit (8-, 16-, or 32-bit unit) DMA transfer. When another transfer request occurs, the bus is obtained from the other bus master and transfer is performed for one transfer unit. When that transfer ends, the bus is passed to the other bus master. This is repeated until the transfer end conditions are satisfied.

In the cycle-steal mode, transfer areas are not affected regardless of the transfer request source, transfer source, and transfer destination settings. Figure 12.14 shows an example of DMA transfer timing in cycle-steal mode. Transfer conditions shown in the figure are:

 $\frac{\text{Dual address mode}}{\text{DREQ} \text{ level detection}}$

Figure 12.14 Example of Transfer in Cycle-Steal Wwwl.DataSheet4U.com Rev. 5.0, 09/03, page 403 of 806

Burst Mode

Once the bus is obtained, the transfer is performed continuously until the transfer end condition is satisfied. In external request mode with low level detection of the \overline{DREQ} pin, however, when the \overline{DREQ} pin is driven high, the bus passes to the other bus master after the DMAC transfer request that has already been accepted ends, even if the transfer end conditions have not been satisfied.

Burst mode cannot be used when a SCIF (IrDA or SCIF) is the transfer request source. Figure 12.15 shows an example of burst mode timing.

Figure 12.15 Example of Transfer in Burst Mode

www.DataSheet4U.com

Relationship between Request Modes and Bus Modes by DMA Transfer Category: Table 12.6 shows the relationship between request modes and bus modes by DMA transfer category.

| Address Mode | Transfer Category | Request Mode | Bus Mode | Transfer Size (Bits) | Usable Channels |
|-----------------|---|-------------------|-------------|-------------------------|--------------------|
| Dual | External device with DACK and external memory | External | B/C | 8/16/32/128 | 0,1 |
| | External device with DACK and memory-mapped external device | External | B/C | 8/16/32/128 | 0, 1 |
| | External memory and external memory | All ^{*1} | B/C | 8/16/32/128 | 0–3 ^{*5} |
| | External memory and memory- mapped external device | All ^{*1} | B/C | 8/16/32/128 | 0–3 ^{*5} |
| | Memory-mapped external device and memory-mapped external device | All ^{*1} | B/C | 8/16/32/128 | 0–3 ^{*5} |
| | External memory and on-chip peripheral module | All ^{*2} | B/C*3 | 8/16/32 ^{*4} | 0–3 ^{*5} |

| | External device with DACK and memory-mapped external device | External | B/C | 8/16/32/128 | 0, 1 |

Table 12.6 Relationship between Request Modes and Bus Modes by DMA Transfer Category Category

B: Burst, C: Cycle-steal

Notes: 1. External requests, auto requests and on-chip peripheral module (CMT) requests are all available.

- External requests, auto requests and on-chip peripheral module requests are all available. When the IrDA, SCI, or A/D converter is also the transfer request source, however, the transfer destination or transfer source must be the IrDA, SCI, or A/D converter, respectively.
- 3. If the transfer request source is the IrDA, SCI, or A/D converter only cycle-steal mode is available.

- 4. The access size permitted when the transfer destination or source is an on-chip peripheral module register.
- 5. If the transfer request is an external request, only channels 0 and 1 are available.

Bus Mode and Channel Priority Order: When, for example, channel 1 is transferring in burst mode and there is a transfer request to channel 0, which has higher priority, the channel 0 transfer will begin immediately.

At this time, if the priority is set in the fixed mode (CH0 > CH1), the channel 1 transfer will continue when the channel 0 transfer has completely finished, even if channel 0 is operating in cycle-steal mode or burst mode.

If the priority is set in round-robin mode, channel 1 will begin operating again after channel 0 completes the transfer of one transfer unit, even if channel 0 is in cycle-steal mode or burst mode. The bus will then switch between the two in the order channel 1, channel 0, channel 1, channel 0.

Even if the priority is set in fixed mode or in round-robin mode, the bus will not be given to the CPU since channel 1 is in burst mode. This example is illustrated in figure 12.16.

Figure 12.16 Bus State when Multiple Channels Are Operating

www.DataSheet4U.com

12.3.5 Number of Bus Cycle States and DREQ Pin Sampling Timing

Number of Bus Cycle States: When the DMAC is the bus master, the number of bus cycle states is controlled by the bus state controller (BSC) in the same way as when the CPU is the bus master. For details, see section 11, Bus State Controller (BSC).

DREQ Pin Sampling Timing: In external request mode, the $\overline{\text{DREQ}}$ pin is sampled by clock pulse (CKIO) falling edge or low level detection. When $\overline{\text{DREQ}}$ input is detected, a DMAC bus cycle is generated and DMA transfer performed, at the earliest, three states later.

The second and subsequent $\overline{\text{DREQ}}$ sampling operations are started two cycles after the first sample.

Operation

Cycle-Steal Mode

In cycle-steal mode, the $\overline{\text{DREQ}}$ sampling timing is the same regardless of whether level or edge detection is used.

For example, in figure 12.17 (cycle-steal mode, level input), DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. The second sampling is started two cycles after the first. If DREQ is not detected at this time, sampling is performed in each subsequent cycle.

Thus, $\overline{\text{DREQ}}$ sampling is performed one step in advance. The third sampling operation is not performed until the idle cycle following the end of the first DMA transfer.

The above conditions are the same whatever the number of CPU transfer cycles, as shown in figure 12.18. The above conditions are also the same whatever the number of DMA transfer cycles, as shown in figure 12.19.

DACK is output in a read in the example in figure 12.17, and in a write in the example in figure 12.18. In both cases, DACK is output for the same duration as $\overline{\text{CSn}}$.

Figure 12.20 shows an example in which sampling is executed in all subsequent cycles when DREQ cannot be detected.

Figure 12.21 shows examples of edge detection in the cycle-steal mode.

www.DataSheet4U.com Rev. 5.0, 09/03, page 407 of 806

• Burst Mode, Level Detection

In the case of burst mode with level detection, the $\overline{\text{DREQ}}$ sampling timing is the same as in cycle-steal mode.

For example, in figure 12.22, DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. The second sampling is started two cycles after the first. Subsequent sampling operations are performed in the idle cycle following the end of the DMA transfer cycle.

In burst mode, also, the DACK output period is the same as in cycle-steal mode.

Burst Mode, Edge Detection
 In the case of burst mode with edge detection, DREQ sampling is only performed once.

For example, in figure 12.23, DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. After this, DMAC transfer is executed continuously until the number of data transfers set in the DMATCR register have been completed. $\overline{\text{DREQ}}$ is not sampled during this time.

To restart DMA transfer after it has been suspended by an NMI, first clear NMIF, then input an edge request again.

In burst mode, also, the DACK output period is the same as in cycle-steal mode.

12.3.6 Source Address Reload Function

Channel 2 includes a reload function, in which the value is returned to the value set in the source address register (SAR2) every four transfers by setting the RO bit in CHCR2. 16-byte transfer cannot be used. Figure 12.24 shows this operation. Figure 12.25 shows a timing chart for the source address reload function under the following conditions: burst mode, auto-request, 16-bit transfer data size, SAR2 incremented, DAR2 fixed, reload function on, and use of channel 2 only.

Figure 12.24 Source Address Reload Function Diagram

Figure 12.25 Timing Chart of Source Address Reload Function

The reload function can be executed with a transfer data size of 8, 16, or 32 bits.

DMATCR2, which specifies the transfer count, increments 1 each time a transfer ends regardless of whether the reload function is on or off. Consequently, a multiple of four must be specified in DMATCR2 when the reload function is on. Operation is not guaranteed if other values are specified.

The counter that counts the execution of four transfers for the reload function is reset by clearing the DME bit in DMAOR or the DE bit in CHCR2, by setting the transfer end flag (TE bit in CHCR2), and by NMI input, as well as by a reset or standby transition, but the SAR2, DAR2, and DMATCR2 registers are not reset. Therefore, if these sources are generated, there will be a mix of an initialized counter and uninitialized registers in the DMAC, and a malfunction will be caused by restarting the DMAC in that state. Consequently, if one of these sources other than setting of the TE bit occurs during use of the reload function, set SAR2, DAR2, and DMATCR2 again.

www.DataSheet4U.com Rev. 5.0, 09/03, page 417 of 806

12.3.7 DMA Transfer Ending Conditions

The DMA transfer ending conditions are different for ending on an individual channel and ending on all channels together. At the end of transfer, the following conditions are applied except in the case where the value set in the DMA transfer count register (DMATCR) reaches 0.

(a) Cycle-steal mode (external request, internal request, and auto-request)

When the transfer ending conditions are satisfied, DMAC transfer request acceptance is suspended. The DMAC stops operating after completing the number of transfers that it has accepted until the ending conditions are satisfied.

In cycle-steal mode, the operation is the same regardless of whether the transfer request is detected by level or edge.

(b) Burst mode, edge detection (external request, internal request, and auto-request)

The timing from the point where the ending conditions are satisfied to the point where the DMAC stops operating is the same as in cycle-steal mode. With edge detection in burst mode, though only one transfer request is generated to start the DMAC, stop request sampling is performed at the same timing as transfer request sampling in cycle-steal mode. As a result, the period when a stop request is not sampled is regarded as the period when a transfer request is generated, and after performing the DMA transfer for this period, the DMAC stops operating.

- (c) Burst mode, level detection (external request) Same as in (a).
- (d) Bus timing when transfer is suspended

Transfer is suspended when one transfer ends. Even if transfer ending conditions are satisfied during a read in direct address transfer in dual address mode, the subsequent write process is executed, and after the transfer in (a) to (c) above has been executed, DMAC operation is suspended.

Individual Channel Ending Conditions: There are two ending conditions. A transfer ends when the value of the channel's DMA transfer count register (DMATCR) is 0, or when the DE bit in the channel's CHCR register is cleared to 0.

- When DMATCR is 0: When the DMATCR value becomes 0 and the corresponding channel's DMA transfer ends, the transfer end flag bit (TE) is set in CHCR. If the IE (interrupt enable) bit has been set, a DMAC interrupt (DEI) request is sent to the CPU. This transfer ending does not apply to (a) to (d) described above.
- When DE in CHCR is 0: Software can halt a DMA transfer by clearing the DE bit in the channel's CHCR register. The TE bit is not set when this happens. This transfer ending applies to (a) to (d) described above.

Conditions for Ending on All Channels Simultaneously: Transfers on all channels end (1) when the NMIF (NMI flag) bit is set to 1 in DMAOR, or (2) when the DME bit in DMAOR is cleared to 0.

- Transfer ending when the NMIF bit is set to 1 in DMAOR: When an NMI interrupt occurs, the NMIF bit is set to 1 in DMAOR and all channels stop their transfers according to the conditions in (a) to (d) described above, and pass the bus to an other bus master. Consequently, even if the NMI bit is set to 1 during transfer, SAR, DAR, DMATCR are updated. The TE bit is not set. To resume transfer after NMI interrupt exception handling, clear the NMIF bit to 0. At this time, if there are channels that should not be restarted, clear the corresponding DE bit in CHCR.
- Transfer ending when DME is cleared to 0 in DMAOR: Clearing the DME bit to 0 in DMAOR forcibly aborts transfer on all channels. The TE bit is not set. All channels abort their transfer according to the conditions in (a) to (d) in section 12.3.7, DMA Transfer Ending Conditions, as in NMI interrupt generation. In this case, the values in SAR, DAR, and DMATCR are also updated.

12.4 Compare Match Timer (CMT)

12.4.1 Overview

The DMAC has an on-chip compare match timer (CMT) to generate DMA transfer requests. The CMT has a 16-bit counter.

Features

The CMT has the following features:

- Four types of counter input clock can be selected
 - One of four internal clocks ($P\phi/4$, $P\phi/8$, $P\phi/16$, $P\phi/64$) can be selected.
- Generates a DMA transfer request when compare match occurs.

Block Diagram

Figure 12.26 shows a block diagram of the CMT.

Figure 12.26 Block Diagram of CMT

Register Configuration

Table 12.7 summarizes the CMT register configuration.

Table 12.7 Register Configuration

| Name ^{www.DataSheet4U.com} | Abbreviation | R/W | Initial Value | Address | Access Size (Bits) |
|---|--------------|---------|------------------|--|-----------------------|
| Compare match timer start register | CMSTR | R/(W) | H'0000 | H'04000070 (H'A4000070) ^{*2} | 8, 16, 32 |
| Compare match timer control/status register 0 | CMCSR0 | R/(W)*1 | H'0000 | H'04000072 (H'A4000072) ^{*2} | 8, 16, 32 |
| Compare match counter 0 | CMCNT0 | R/W | H'0000 | H'04000074 (H'A4000074) ^{*2} | 8, 16, 32 |
| Compare match constant register 0 | CMCOR0 | R/W | H'FFFF | H'04000076 (H'A4000076) ^{*2} | 8, 16, 32 |

Notes: 1. The only value that can be written to the CMF bit in CMCSR0 is 0 to clear the flag.

2. When address translation by the MMU does not apply, the address in parentheses should be used.

12.4.2 Register Descriptions

Compare Match Timer Start Register (CMSTR)

The compare match timer start register (CMSTR) is a 16-bit register that selects whether compare match counter 0 (CMCNT0) is operated or halted. It is initialized to H'0000 by a reset, but retains its previous value in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|----|----|----|----|----|----|-----|------|
| | _ | | | | | | | _ |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | _ | — | — | — | — | — | — | STR0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R/W | R/W |

Bits 15 to 2—Reserved: These bits are always read as 0. The write value should alway be 0.

Bit 1—Reserved: This bit can be read or written. The write value should always be 0.

www.DataSheet4U.com Rev. 5.0, 09/03, page 421 of 806

Bit 0—Count Start 0 (STR0): Selects whether to operate or halt compare match timer counter 0.

| Bit 0: STR0 | Description | |
|-------------|-------------------------------|-----------------|
| 0 | CMCNT0 count operation halted | (Initial value) |
| 1 | CMCNT0 count operation | |

www.DataSheet4U.com

Compare Match Timer Control/Status Register 0 (CMCSR0)

The compare match timer control/status register 0 (CMCSR0) is a 16-bit register that indicates the occurrence of compare matches, sets the enable/disable status of interrupts, and establishes the clock used for incrementation. It is initialized to H'0000 by a reset, but retains its previous value in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|--------|-----|----|----|----|----|------|------|
| | — | | — | | — | _ | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | CMF | — | — | — | — | — | CKS1 | CKS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/(W)* | R/W | R | R | R | R | R/W | R/W |

Note: * The only value that can be written is 0 to clear the flag.

Bits 15 to 8 and 5 to 2—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 7—Compare Match Flag (CMF): Indicates whether or not the compare match timer counter 0 CMCNT0 and compare match timer constant 0 (CMCOR0) values match.

| Bit 7: CMF | Description | |
|------------|--|-----------------|
| 0 | CMCNT0 and CMCOR0 values do not match | (Initial value) |
| | Clearing condition: Write 0 to CMF after reading CMF = 1 | |
| 1 | CMCNT0 and CMCOR0 values match | |

www.DataSheet4U.com

Bit 6—Reserved: This bit can be read or written. The wite value should always be 0.

Bits 1 and 0—Clock Select 1 and 0 (CKS1, CKS0): Select the clock input to CMCNT from among the four internal clocks obtained by dividing the system clock ($P\phi$). When the STR bit in CMSTR is set to 1, CMCNT0 begins incrementing on the clock selected by CKS1 and CKS0.

| Bit 1: CKS1ata | Sh Bit 0: CKS0 | Description | |
|----------------|-----------------------|-------------|-----------------|
| 0 | 0 | Ρ φ/4 | (Initial value) |
| | 1 | Ρ φ/8 | |
| 1 | 0 | Р ф/16 | |
| | 1 | P | |

Compare Match Counter 0 (CMCNT0)

Compare match counter 0 (CMCNT0) is a 16-bit register used as an up-counter.

When an internal clock is selected with the CKS1 and CKS0 bits in the CMCSR0 register and the STR bit in CMSTR is set to 1, CMCNT0 begins incrementing on that clock. When the CMCNT0 value matches that of compare match constant register 0 (CMCOR0), CMCNT0 is cleared to H'0000 and the CMF flag in CMCSR0 is set to 1.

CMCNT0 is initialized to H'0000 by a reset, but retains its previous value in standby mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|
| | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W |

Compare Match Constant Register 0 (CMCOR0)

Compare match constant register 0 (CMCOR0) is a 16-bit register that sets the CMCNT0 compare match period.

CMCOR0 is initialized to H'FFFF by a reset, but retains its previous value in standby mode.

12.4.3 Operation

Period Count Operation

When an internal clock is selected with the CKS1 and CKS0 bits in the CMCSR0 register and the STR bit in CMSTR is set to 1, CMCNT0 begins incrementing on the selected clock. When the CMCNT counter value matches that of CMCOR0, the CMCNT0 counter is cleared to H'0000 and the CMF flag in the CMCSR0 register is set to 1. The CMCNT0 counter begins counting up again from H'0000.

Figure 12.27 shows the compare match counter operation.

Figure 12.27 Counter Operation

www.DataSheet4U.com

CMCNT0 Count Timing

One of four clocks ($P\phi/4$, $P\phi/8$, $P\phi/16$, $P\phi/64$) obtained by dividing the $P\phi$ clock can be selected with the CKS1 and CKS0 bits in CMCSR0. Figure 12.28 shows the timing.

Figure 12.28 Count Timing

12.4.4 Compare Match

Compare Match Flag Setting Timing

The CMF bit in the CMCSR0 register is set to 1 by the compare match signal generated when the CMCOR0 register and the CMCNT0 counter match. The compare match signal is generated in the final state of the match (timing at which the CMCNT0 counter matching count value is updated). Consequently, after the CMCOR0 register and the CMCNT0 counter match, a compare match signal will not be generated until a CMCNT0 counter input clock occurs. Figure 12.29 shows the CMF bit setting timing.

| СК | | |
|-------------------------|-----|--|
| CMCNT0 input clock | | |
| www.DataSheet4U.com | | |
| CMCNT0 | N 0 | |
| CMCOR0 | N | |
| Compare match signal | | |
| CMF | | |
| СМІ | | |

Compare Match Flag Clearing Timing

The CMF bit in the CMCSR0 register is cleared by writing 0 to it after reading 1. Figure 12.30 shows the timing when the CMF bit is cleared by the CPU.

Figure 12.30 Timing of CMF Clearing by the CPU

12.5 Examples of Use

12.5.1 Example of DMA Transfer between On-Chip IrDA and External Memory

In this example, receive data of the on-chip IrDA is transferred to external memory using DMAC channel 3. Table 12.8 shows the transfer conditions and register settings. In addition, it is recommended that the trigger for the number of receive FIFO data bytes in IrDA be set to 1 (RTRG1 = RTRG0 = 0 in SCFCR).

Table 12.8 Transfer Conditions and Register Settings for Transfer between On-Chip SCI and External Memory

| Transfer Conditions | Register | Setting | |
|--|----------|------------|--|
| Transfer source: RDR1 of on-chip IrDA | SAR3 | H'0400014A | |
| Transfer destination: External memory | DAR3 | H'00400000 | |
| Number of transfers: 64 | DMATCR3 | H'00000040 | |
| Transfer source address: Fixed | CHCR3 | H'00004B05 | |
| Transfer destination address: Incremented | | | |
| Transfer request source: IrDA (RXI1) | | | |
| Bus mode: Cycle-steal | | | |
| Transfer unit: Byte | | | |
| Interrupt request generated at end of transfer | | | |
| Channel priority order: 0 > 2 > 3 > 1 | DMAOR | H'0101 | |

12.5.2 Example of DMA Transfer between A/D Converter and External Memory (Address Reload On)

In this example, DMA transfer is performed between the on-chip A/D converter (transfer source) and the external memory (transfer destination) with the address reload function on. Table 12.9 shows the transfer conditions and register settings.

www.DataSheet4U.com

Table 12.9 Transfer Conditions and Register Settings for Transfer between On-Chip A/D Converter and External Memory

| Transfer Conditions | Register | Setting |
|--|----------|------------|
| Transfer source: On-chip A/D converter | SAR2 | H'0400080 |
| Transfer destination: External memory | DAR2 | H'00400000 |
| Number of transfers: 128 (reloading 32 times) | DMATCR2 | H'0000080 |
| Transfer source address: Incremented | CHCR2 | H'00089E35 |
| Transfer destination address: Decremented | | |
| Transfer request source: A/D converter | | |
| Bus mode: Burst | | |
| Transfer unit: Longword | | |
| Interrupt request generated at end of transfer | | |
| Channel priority order: 0 > 2 > 3 > 1 | DMAOR | H'0101 |

When the address reload function is on, the value set in SAR returns to the initially set value every four transfers. In this example, when an interrupt request is generated from the A/D converter, byte data is read from the register at address H'04000080 in the A/D converter, and is written to external memory address H'00400000. Since longword data has been transferred, the values in SAR and DAR are H'04000084 and H'003FFFFC, respectively. The bus is kept and data transfers are performed successively because this transfer is in burst mode.

After four transfers end, fifth and sixth transfers are performed if the address reload function is off, and the value in SAR is incremented from H'0400008C to H'04000090, H'04000094... If the address reload function is on, DMA transfer stops after the fourth transfer ends, and the bus request signal to the CPU is cleared. At this time, the value stored in SAR is not incremented from H'0400008C to H'04000090, but returns to the initially set value, H'04000080. The value in DAR continues to be incremented regardless of whether the address reload function is on or off.

www.DataSheet4U.com

As a result, the values in the DMAC are as shown in table 12.10 when the fourth transfer ends, depending on whether the address reload function is on or off.

| Items | Address reload on | Address reload off |
|---------------------------------------|-------------------|--------------------|
| SAR www.DataSheet4U.com | H'0400080 | H'04000090 |
| DAR | H'003FFFFC | H'003FFFFC |
| DMATCR | H'000007C | H'000007C |
| Bus | Released | Held |
| DMAC operation | Stops | Keeps operating |
| Interrupt | Not generated | Not generated |
| Transfer request source flag clearing | Executed | Not executed |

| Table 12.10 | Values in | DMAC after | End of Fourth | Transfer |
|-------------|-----------|------------|---------------|----------|
|-------------|-----------|------------|---------------|----------|

Notes: 1. An interrupt is generated regardless of whether the address reload function is on or off, if transfers are executed until the value in DMATCR reaches 0 and the IE bit in CHCR has been set to 1.

2. The transfer request source flag is cleared regardless of whether the address reload function is on or off, if transfers are executed until the value in DMATCR reaches 0.

3. Specify burst mode when using the address reload function. This function may not be correctly executed in cycle-steal mode.

4. Set a multiple of four in DMATCR when using the address reload function. This function may not be correctly executed if other values are specified.

12.5.3 Example of DMA Transfer between External Memory and SCIF Transmitter (Indirect Address On)

In this example, DMA transfer is performed between the external memory specified by indirect address (transfer source) and the SCIF transmitter (transfer destination) using DMAC channel 3. Table 12.11 shows the transfer conditions and register settings. In addition, the trigger for the number of transmit FIFO data bytes is set to 1 (TTRG1 = TTRG0 = 1 in SCFCR).

www.DataSheet4U.com Rev. 5.0, 09/03, page 429 of 806

Table 12.11 Transfer Conditions and Register Settings for Transfer between External Memory and SCIF Transmitter

| Transfer Conditions | Register | Setting |
|---|----------|------------|
| Transfer source: External memory | SAR3 | H'00400000 |
| Value stored in address H'00400000 | _ | H'00450000 |
| Value stored in address H'04500000 | _ | H'55 |
| Transfer destination: On-chip SCIF TDR2 | DAR3 | H'04000156 |
| Number of transfers: 10 | DMATCR3 | H'0000000A |
| Transfer source address: Incremented | CHCR3 | H'00011C01 |
| Transfer destination address: Fixed | | |
| Transfer request source: SCIF (TXI2) | | |
| Bus mode: Cycle-steal | | |
| Transfer unit: Byte | | |
| No interrupt request generated at end of transfer | | |
| Channel priority order: 0 > 1 > 2 > 3 | DMAOR | H'0001 |

If the indirect address is on, data stored in the address set in SAR is not used as transfer source data. In the indirect address, after the value stored in the address set in SAR is read, that read value is used as an address again, and the value stored in that address is read and stored in the address set in DAR.

In the example shown in table 12.11, when an SCIF transfer request is generated, the DMAC reads the value in address H'00400000 set in SAR3. Since the value H'00450000 is stored in that address, the DMAC reads the value H'00450000. Next, the DMAC uses that read value as an address again, and reads the value H'55 stored in that address. Then, the DMAC writes the value H'55 to address H'04000156 set in DAR3; this completes one indirect address transfer.

In the indirect address, when data is read first from the address set in SAR3, the data transfer size is always longword regardless of the settings of the TS0 and TS1 bits that specify the transfer data size. However, whether the transfer source address is fixed, incremented, or decremented is specified by the SM0 and SM1 bits. Therefore, in this example, though the transfer data size is specified as byte, the value in SAR3 is H'00400004 when one transfer ends. Write operations are the same as in normal dual address transfer.

www.DataSheet4U.com

12.6 Usage Notes

- 1. The DMA channel control registers (CHCR0–CHCR3) can be accessed with any data size. The DMA operation register (DMAOR) must be accessed by byte (eight bits) or word (16 bits); other registers must be accessed by word (16 bits) or longword (32 bits).
- 2. Before rewriting the RS0–RS3 bits in CHCR0–CHCR3, first clear the DE bit to 0 (when rewriting CHCR with a byte address, be sure to set the DE bit to 0 in advance).
- 3. Even if an NMI interrupt is input when the DMAC is not operating, the NMIF bit in DMAOR will be set.
- 4. Before entering standby mode, the DME bit in DMAOR must be cleared to 0 and the transfers accepted by the DMAC completed.
- 5. The on-chip peripherals which the DMAC can access are the IRDA, SCIF, A/D converter, D/A converter, and I/O ports. Do not access other peripherals with the DMAC.
- 6. When starting up the DMAC, set CHCR or DMAOR last. Normal operation is not guaranteed if settings for another register are made last.
- 7. Even if the maximum number of transfers are performed in the same channel after the DMATCR count reaches 0 and DMA transfer ends normally, write 0 to DMATCR. Otherwise, normal DMA transfer may not be performed.
- 8. When using the address reload function, specify burst mode as the transfer mode. In cycle-steal mode, normal DMA transfer may not be performed.
- 9. When using the address reload function, set a multiple of four in DMATCR. Normal operation is not guaranteed if other values are specified.
- 10. When detecting an external request at the falling edge, keep the external request pin high when setting the DMAC.
- 11. Do not access the space from H'4000062 to H'400006F, which is not used in the DMAC. Accessing this space may cause malfunctions.
- 12. The WAIT signal is ignored in the case of a write to external address space in dual address mode with 16-byte transfer, or transfer from an external device with DACK to external address space in single address mode with 16-byte transfer.
- 13. DMAC transfers should not be performed in the sleep mode under conditions other than when the clock ratio of I ϕ (on-chip clock) to B ϕ (bus clock) is 1:1.
- 14. When the following three conditions are all met, the frequency control register (FRQCR) should not be changed while a DMAC transfer is in progress.
 - Bits IFC2 to IFC0 are changed.
 - STC2 to STC0 in FRQCR are not changed.
 - The clock ratio of I ϕ (on-chip clock) to B ϕ (bus clock) after the change is other than 1:1.
- 15. If the following three conditions are all met, big-endian access is used when the DMAC is used to transfer data from XY memory, even in the little-endian mode.
 - The source address for the transfer is in XY memory.
 - The indirect address mode is used.

www.DataSheet4U.com Rev. 5.0, 09/03, page 431 of 806

- The byte size data is transferred.
- The data format is little-endian.

Section 13 Timer (TMU)

13.1 Overview

The SH7729R has a three-channel (channels 0 to 2) 32-bit timer unit (TMU). www.DataSheet4U.com

13.1.1 Features

The TMU has the following features:

- Each channel is provided with an auto-reload 32-bit down counter
- Channel 2 is provided with an input capture function
- All channels are provided with 32-bit constant registers and 32-bit down counters that can be read or written to at any time.
- All channels generate interrupt requests when the 32-bit down counter underflows (H'00000000 → H'FFFFFFF).
- Allows selection between 6 counter input clocks: External clock (TCLK), on-chip RTC output clock (16 kHz), Pφ/4, Pφ/16, Pφ/64, Pφ/256. (Pφ is the internal clock for peripheral modules.) See section 10, On-Chip Oscillation Circuits, for more information on the clock pulse generator.
- All channels can operate when the SH7729R is in standby mode: When the RTC output clock is being used as the counter input clock, the SH7729R is still able to count in standby mode.
- Synchronized read: TCNT is a sequentially changing 32-bit register. Since the peripheral module used has an internal bus width of 16 bits, a time lag can occur between the time when the upper 16 bits and lower 16 bits are read. To correct the discrepancy in the counter read value caused by this time lag, a synchronization circuit is built into the TCNT so that the entire 32-bit data in the TCNT can be read at once.
- The maximum operating frequency of the 32-bit counter is 2 MHz on all channels: Operate the SH7729R so that the clock input to the timer counters of each channel (obtained by dividing the external clock and internal clock with the prescaler) does not exceed the maximum operating frequency.

| | Input capture register 2 | TCPR2 | R | Undefined | H'FFFFFEB8 | 32 |

Note: * Initialized by power-on resets or manual resets.

13.2 TMU Registers

13.2.1 Timer Output Control Register (TOCR)

TOCR is an 8-bit readable/writable register that selects whether to use the external TCLK pin as an external clock or an input capture control usage input pin, or an output pin for the on-chip RTC output clock. TOCR is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|---|---|---|---|---|---|------|
| | _ | _ | _ | | | _ | | TCOE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R/W |

Bits 7 to 1—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 0—Timer Clock Pin Control (TCOE): Selects use of the timer clock pin (TCLK) as an external clock output pin or input pin for input capture control for the on-chip timer, or as an output pin for the on-chip RTC output clock. Since the TCLK pin is multiplexed as the PTH7 pin, when the pin is used as TCLK, bits PH7MD1 and PH7MD0 in the PHCR register should be set to 00 (the "other function" setting).

| Bit 0: TCOE | Description | |
|-------------|--|--|
| 0 | Timer clock pin (TCLK) used as external clock inp input pin for the on-chip timer | ut or input capture control (Initial value) |
| 1 | Timer clock pin (TCLK) used as output pin for on- | chip RTC output clock |

13.2.2 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects whether to run or halt the timer counters (TCNT) for channels 0–2. TSTR is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode when the input clock selected for the channel is the on-chip RTC clock (RTCCLK). Only when an external clock (TCLK) or the peripheral clock (P ϕ) is used as the input clock, it is initialized in standby mode when the multiplication ratio of PLL circuit 1 is changed or when the MSTP2 bit in STBCR is set to 1.

www.DataSheet4U.com

Bits 7 to 3—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 2—Counter Start 2 (STR2): Selects whether to run or halt timer counter 2 (TCNT2).

| Bit 2 | 2: STR2 | Description | |
|-------|----------------|--------------------|-----------------|
| 0 | | TCNT2 count halted | (Initial value) |
| 1 | www.DataSheet4 | TCNT2 counts | |

Bit 1—Counter Start 1 (STR1): Selects whether to run or halt timer counter 1 (TCNT1).

| Bit 1: STR1 | Description | |
|-------------|--------------------|-----------------|
| 0 | TCNT1 count halted | (Initial value) |
| 1 | TCNT1 counts | |

Bit 0—Counter Start 0 (STR0): Selects whether to run or halt timer counter 0 (TCNT0).

| Bit 0: STR0 | Description | |
|-------------|--------------------|-----------------|
| 0 | TCNT0 count halted | (Initial value) |
| 1 | TCNT0 counts | |

13.2.3 Timer Control Registers (TCR)

The timer control registers (TCR) control the timer counters (TCNT) and interrupts. The TMU has three TCR registers, one for each channel.

The TCR registers are 16-bit readable/writable registers that control the issuance of interrupts when the flag indicating timer counter (TCNT) underflow has been set to 1, and also carry out counter clock selection. When the external clock has been selected, they also select its edge. Additionally, TCR2 controls the channel 2 input capture function and the issuance of interrupts during input capture. The TCR registers are initialized to H'0000 by a power-on reset and manual reset, but are not initialized in standby mode.

www.DataSheet4U.com Rev. 5.0, 09/03, page 437 of 806

Channels 0 and 1 TCR Bit Configuration:

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-------------------|---------------|-------|------|-------|-------|-------|-------|-------|

| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | ICPE1 | ICPE0 | UNIE | CKEG1 | CKEG0 | TPSC2 | TPSC1 | TPSC0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bits 15 to 10, 9 (except TCR2), 7, and 6 (except TCR2)—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 9—Input Capture Interrupt Flag (ICPF): A function of channel 2 only: the flag is set when input capture is requested via the TCLK pin.

| Bit 9: ICPF | Description | |
|-------------|--|-----------------|
| 0 | No input capture request has been issued Clearing condition: When 0 is written to ICPF | (Initial value) |
| 1 | Input capture has been requested via the TCLK pin Setting condition: When input capture is requested via the TCLK | (pin* |

Note: * Contents do not change when 1 is written to ICPF.

Bit 8—Underflow Flag (UNF): Status flag that indicates occurrence of a TCNT underflow.

| Bit 8: UNF | Description | |
|-------------|---|-----------------|
| 0 | TCNT has not underflowed Clearing condition: When 0 is written to UNF | (Initial value) |
| 1 www.Da | TCNT has underflowed (H'00000000 \rightarrow H'FFFFFFF) taSh Setting condition: When TCNT underflows [*] | |
| | | |

Note: * Contents do not change when 1 is written to UNF.

Bits 7 and 6—Input Capture Control (ICPE1, ICPE0): A function of channel 2 only: determines whether the input capture function can be used, and when used, whether or not to enable interrupts.

When using this input capture function it is necessary to set the TCLK pin to input mode with the TCOE bit in the TOCR register. Additionally, use the CKEG bit to designate use of either the rising or falling edge of the TCLK pin to set the value in TCNT2 in the input capture register (TCPR2).

| Bit 7: ICPE1 | Bit 6: ICPE0 | Description |
|--------------|--------------|---|
| 0 | 0 | Input capture function is not used (Initial value) |
| | 1 | Reserved (Setting prohibited) |
| 1 | 0 | Input capture function is used. Interrupt due to ICPF (TICPI2) is not enabled |
| | 1 | Input capture function is used. Interrupt due to ICPF (TICPI2) is enabled |

Bit 5—Underflow Interrupt Control (UNIE): Controls enabling of interrupt generation when the status flag (UNF) indicating TCNT underflow has been set to 1.

| Bit 5: UNIE | Description | |
|-------------|--|-----------------|
| 0 | Interrupt due to UNF (TUNI) is not enabled | (Initial value) |
| 1 | Interrupt due to UNF (TUNI) is enabled | |

Bits 4 and 3—Clock Edge 1 and 0 (CKEG1, CKEG0): Select the external clock edge when the external clock is selected, or when the input capture function is used.

| 0 0 Count/capture register set on rising edge | |
|--|-----------------|
| | (Initial value) |
| 1 Count/capture register set on falling edge | |
| 1 X Count/capture register set on both rising and fallin | ng edge |

Note: X means 0, 1, or 'Don't care'.

| Bits 2 to 0—Timer Prescaler 2 to 0 (TPSC2 to TPSC0): Select the TCNT co |
|---|
|---|

| Bit 2: TPSC2 | Bit 1: TPSC1 | Bit 0: TPSC0 | Description |
|--------------|--------------|--------------|--|
| 0 | 0 | 0 | Internal clock: count on P |
| | | 1 | Internal clock: count on Pø/16 |
| | 1 | 0 | Internal clock: count on Pø/64 |
| | | 1 | Internal clock: count on Pø/256 |
| 1 | 0 | 0 | Internal clock: count on clock output of on-chip RTC (RTCCLK) |
| | | 1 | External clock: count on TCLK pin input |
| | 1 | 0 | Reserved (Setting prohibited) |
| | | 1 | Reserved (Setting prohibited) |

13.2.4 Timer Constant Registers (TCOR)

The timer constant registers are 32-bit registers. The TMU has three TCOR registers, one for each channel.

TCOR is a 32-bit readable/writable register. When a TCNT count-down results in an underflow, the TCOR value is set in TCNT and the count-down continues from that value. TCOR is initialized to H'FFFFFFFF by a power-on reset or manual reset, but is not initialized, and retains its contents, in standby mode.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W |
| | | | | | | | | |
| Bit: | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W |
| | | | | | | | | |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W |

13.2.5 Timer Counters (TCNT)

The timer counters are 32-bit readable/writable registers. The TMU has three timer counters, one for each channel.

TCNT counts down upon input of a clock. The clock input is selected using the TPSC2–TPSC0 bits in the timer control register (TCR).

When a TCNT count-down results in an underflow (H'00000000 \rightarrow H'FFFFFFF), the underflow flag (UNF) in the timer control register (TCR) of the relevant channel is set. The TCOR value is simultaneously set in TCNT itself and the count-down continues from that value.

Because the internal bus for the SH7729R on-chip peripheral modules is 16 bits wide, a time lag can occur between the time when the upper 16 bits and lower 16 bits are read. Since TCNT counts sequentially, this time lag can create discrepancies between the data in the upper and lower halves. To correct the discrepancy, a buffer register is connected to TCNT so that the upper and lower halves are not read separately. The entire 32-bit data in TCNT can thus be read at once.

TCNT is initialized to H'FFFFFFF by a power-on reset or manual reset, but is not initialized, and retains its contents, in standby mode.

www.DataSheet4U.com

13.2.6 Input Capture Register (TCPR2)

Input capture register 2 (TCPR2) is a read-only 32-bit register provided only in timer 2. Control of TCPR2 setting conditions due to the TCLK pin is affected by the input capture function bits (ICPE1/ICPE2 and CKEG1/CKEG0) in TCR2. When a TCPR2 setting indication due to the TCLK pin occurs, the value of TCNT2 is copied into TCPR2.

www.DataShee

TCNT2 is not initialized by a power-on reset or manual reset, or in standby mode.

www.DataSheet4U.com Rev. 5.0, 09/03, page 443 of 806

13.3 TMU Operation

13.3.1 Overview

Each of three channels has a 32-bit timer counter (TCNT) and a 32-bit timer constant register (TCOR). TCNT counts down. The auto-reload function enables synchronized counting and counting by external events. Channel 2 has an input capture function.

13.3.2 Basic Functions

Counter Operation: When the STR0–STR2 bits in the timer start register (TSTR) are set, the corresponding timer counter (TCNT) starts counting. When a TCNT underflows, the UNF flag of the corresponding timer control register (TCR) is set. At this time, if the UNIE bit in TCR is 1, an interrupt request is sent to the CPU. Also at this time, the value is copied from TCOR to TCNT and the down-count operation is continued.

The count operation is set as follows (figure 13.2):

- 1. Select the counter clock with the TPSC2–TPSC0 bits in the timer control register (TCR). If the external clock is selected, set the TCLK pin to input mode with the TOCE bit in TOCR, and select its edge with the CKEG1 and CKEG0 bits in TCR.
- 2. Use the UNIE bit in TCR to set whether to generate an interrupt when TCNT underflows.
- 3. When using the input capture function, set the ICPE bits in TCR, including the choice of whether or not to use the interrupt function (channel 2 only).
- 4. Set a value in the timer constant register (TCOR) (the cycle is the set value plus 1).
- 5. Set the initial value in the timer counter (TCNT).
- 6. Set the STR bit in the timer start register (TSTR) to 1 to start operation.

Figure 13.2 Setting the Count Operation

Figure 13.3 Auto-Reload Count Operation

TCNT Count Timing:

 Internal Clock Operation: Set the TPSC2–TPSC0 bits in TCR to select whether peripheral module clock Pφ or one of the four internal clocks created by dividing it is used (Pφ/4, Pφ/16, Pφ/64, Pφ/256). Figure 13.4 shows the timing.

Figure 13.4 Count Timing when Operating on Internal Clock

• External Clock Operation: Set the TPSC2–TPSC0 bits in TCR to select the external clock (TCLK) as the timer clock. Use the CKEG1 and CKEG0 bits in TCR to select the detection edge. Rising, falling, or both edges may be selected. The pulse width of the external clock must be at least 1.5 peripheral module clock cycles for single edges or 2.5 peripheral module clock cycles for both edges. A shorter pulse width will result in accurate operation. Figure 13.5 shows the timing for both-edge detection.

Figure 13.5 Count Timing when Operating on External Clock (Both Edges Detected)

• On-Chip RTC Clock Operation: Set the TPSC2–TPSC0 bits in TCR to select the on-chip RTC clock as the timer clock. Figure 13.6 shows the timing.

Figure 13.6 Count Timing when Operating on On-Chip RTC Clock

Input Capture Function: Channel 2 has an input capture function (figure 13.7). When using the input capture function, set the TCLK pin to input mode with the TCOE bit in the timer output control register (TOCR) and set the timer operation clock to internal clock or on-chip RTC clock with the TPCS2–TPCS0 bits in the timer control register (TCR2). Also, designate use of the input capture function and whether to generate interrupts on input capture with the IPCE1–IPCE0 bits in TCR2, and designate the use of either the rising or falling edge of the TCLK pin to set the timer counter (TCNT2) value into the input capture register (TCPR2) with the CKEG1–CKEG0 bits in TCR2.

The input capture function cannot be used in standby mode.

Figure 13.7 Operation Timing when Using Input Capture Function (Using TCLK Rising Edge)

13.4 Interrupts

There are two sources of TMU interrupts: underflow interrupts (TUNI) and interrupts when using the input capture function (TICPI2).

13.4.1 Status Flag Setting Timing

UNF is set to 1 when the TCNT underflows. Figure 13.8 shows the timing.

Figure 13.8 UNF Setting Timing

13.4.2 Status Flag Clearing Timing

The status flag can be cleared by writing 0 from the CPU. Figure 13.9 shows the timing.

Figure 13.9 Status Flag Clearing Timing

13.4.3 Interrupt Sources and Priorities

The TMU produces underflow interrupts for each channel. When the interrupt request flag and interrupt enable bit are both set to 1, an interrupt is requested. Codes are set in the interrupt event registers (INTEVT, INTEVT2) for these interrupts and interrupt handling occurs according to the codes.

The relative priorities of channels can be changed using the interrupt controller (see section 4, Exception Handling, and section 7, Interrupt Controller (INTC)). Table 13.3 lists TMU interrupt sources.

| Channel | Interrupt Source | Description | Priority |
|---------|------------------|---------------------------|----------|
| 0 | TUNI0 | Underflow interrupt 0 | High |
| 1 | TUNI1 | Underflow interrupt 1 | ▲ |
| 2 | TUNI2 | Underflow interrupt 2 | v |
| 2 | TICPI2 | Input capture interrupt 2 | Low |

| Table 13.3 | TMU Interrupt Sources |
|------------|------------------------------|
|------------|------------------------------|

13.5 Usage Notes

13.5.1 Writing to Registers

Synchronization processing is not performed for timer counting during register writes. When writing to registers, always clear the appropriate start bits for the channel (STR2–STR0) in the timer start register (TSTR) to halt timer counting.

13.5.2 Reading Registers

Synchronization processing is performed for timer counting during register reads. When timer counting and register read processing are performed simultaneously, the register value before TCNT counting down (with synchronization processing) is read.

Section 14 Realtime Clock (RTC)

14.1 Overview

The SH7729R has a realtime clock (RTC) with its own 32.768-kHz crystal oscillator. www.DataSheet4U.com

14.1.1 Features

- Clock and calendar functions (BCD display): Seconds, minutes, hours, date, day of the week, month, and year
- 1-Hz to 64-Hz timer (binary display)
- Start/stop function
- 30-second adjust function
- Alarm interrupt: Frame comparison of seconds, minutes, hours, date, day of the week, and month can be used as conditions for the alarm interrupt
- Cyclic interrupts: The interrupt cycle may be 1/256 second, 1/64 second, 1/16 second, 1/4 second, 1/2 second, 1 second, or 2 seconds
- Carry interrupt: A carry interrupt indicates when a carry occurs during a counter read
- Automatic leap year correction

14.1.2 Block Diagram

Figure 14.1 shows a block diagram of the RTC.

Figure 14.1 Block Diagram of RTC

www.DataSheet4U.com

14.1.3 **Pin Configuration**

Table 14.1 shows the RTC pin configuration.

Table 14.1 RTC Pins

| Pin www.DataSheet4U.com | Abbreviation | I/O | Description |
|------------------------------------|--------------|-----|--|
| RTC oscillator crystal pin | EXTAL2 | I | Connects crystal to RTC oscillator*2 |
| RTC oscillator crystal pin | XTAL2 | 0 | Connects crystal to RTC oscillator*2 |
| Clock input/clock output | TCLK | I/O | External clock input pin/input capture control input pin/realtime clock (RTC) output pin (shared by TMU) |
| Dedicated power-supply pin for RTC | Vcc-RTC | | Dedicated power-supply pin for RTC*1 |
| Dedicated GND pin for RTC | Vss-RTC | | Dedicated GND pin for RTC*1 |
| | | | |

Notes: 1. Except in hardware standby mode, power must be supplied to all power supply pins, including these, even when only the RTC is used (including standby mode).

2. When the RTC is not used, pull EXTAL2 up (to Vcc) and make no connection for XTAL2.

14.1.4 RTC Register Configuration

Table 14.2 shows the RTC register configuration.

Table 14.2RTC Registers

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------------|--------------|-----|---------------|------------|-------------|
| 64-Hz counter | R64CNT | R | Undefined | H'FFFFFEC0 | 8 |
| Second counter | RSECCNT | R/W | Undefined | H'FFFFFEC2 | 8 |
| Minute counter | RMINCNT | R/W | Undefined | H'FFFFFEC4 | 8 |
| Hour counter | RHRCNT | R/W | Undefined | H'FFFFFEC6 | 8 |
| Day of week counter | RWKCNT | R/W | Undefined | H'FFFFFEC8 | 8 |
| Date counter | RDAYCNT | R/W | Undefined | H'FFFFFECA | 8 |
| Month counter | RMONCNT | R/W | Undefined | H'FFFFFECC | 8 |
| Year counter | RYRCNT | R/W | Undefined | H'FFFFFECE | 8 |
| Second alarm register | RSECAR | R/W | Undefined* | H'FFFFFED0 | 8 |
| Minute alarm register | RMINAR | R/W | Undefined* | H'FFFFFED2 | 8 |
| Hour alarm register | RHRAR | R/W | Undefined* | H'FFFFFED4 | 8 |
| Day of week alarm register | RWKAR | R/W | Undefined* | H'FFFFFED6 | 8 |
| Date alarm register | RDAYAR | R/W | Undefined* | H'FFFFFED8 | 8 |
| Month alarm register | RMONAR | R/W | Undefined* | H'FFFFFEDA | 8 |
| RTC control register 1 | RCR1 | R/W | H'00 | H'FFFFFEDC | 8 |
| RTC control register 2 | RCR2 | R/W | H'09 | H'FFFFFEDE | 8 |

Note: * Only the ENB bits of each register are initialized.

14.2 RTC Registers

14.2.1 64-Hz Counter (R64CNT)

The 64-Hz counter (R64CNT) is an 8-bit read-only register that indicates the state of the RTC divider circuit between 64 Hz and 1 Hz.

R64CNT is reset to H'00 by setting the RESET bit in RTC control register 2 (RCR2) or the ADJ bit in RCR2 to 1.

R64CNT is not initialized by a power-on reset or manual reset, or in standby mode.

Bit 7 is always read as 0.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|-----|-----|-----|-----|------|------|------|
| | _ | 1Hz | 2Hz | 4Hz | 8Hz | 16Hz | 32Hz | 64Hz |
| Initial value: | 0 | — | — | — | | | — | |
| R/W: | R | R | R | R | R | R | R | R |

14.2.2 Second Counter (RSECCNT)

The second counter (RSECCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded second section of the RTC. The count operation is performed by a carry for each second of the 64-Hz counter.

The range that can be set is 00–59 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RSECCNT is not initialized by a power-on reset or manual reset, or in standby mode.

14.2.3 Minute Counter (RMINCNT)

The minute counter (RMINCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded minute section of the RTC. The count operation is performed by a carry for each minute of the second counter.

The range that can be set is 00–59 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RMINCNT is not initialized by a power-on reset or manual reset, or in standby mode.

14.2.4 Hour Counter (RHRCNT)

The hour counter (RHRCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded hour section of the RTC. The count operation is performed by a carry for each 1 hour of the minute counter.

The range that can be set is 00–23 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2 or using a carry flag as shown in figure 14.2.

RHRCNT is not initialized by a power-on reset or manual reset, or in standby mode.

14.2.5 Day of Week Counter (RWKCNT)

The day of week counter (RWKCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded day of week section of the RTC. The count operation is performed by a carry for each day of the date counter.

The range that can be set is 0–6 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RWKCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|---|---|---|---|-----|-----------|-----|
| | — | | | | | Ľ | ay of wee | k |
| Initial value: | 0 | 0 | 0 | 0 | 0 | — | _ | _ |
| R/W: | R | R | R | R | R | R/W | R/W | R/W |

Days of the week are coded as shown in table 14.3.

Table 14.3 Day-of-Week Codes (RWKCNT)

| Day of Week | Code | |
|-------------|------|--|
| Sunday | 0 | |
| Monday | 1 | |
| Tuesday | 2 | |
| Wednesday | 3 | |
| Thursday | 4 | |
| Friday | 5 | |
| Saturday | 6 | |

14.2.6 Date Counter (RDAYCNT)

The date counter (RDAYCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded date section of the RTC. The count operation is performed by a carry for each day of the hour counter.

The range that can be set is 01-31 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RDAYCNT is not initialized by a power-on reset or manual reset, or in standby mode.

The RDAYCNT range that can be set changes with each month and in leap years. Please confirm the correct setting.

14.2.7 Month Counter (RMONCNT)

The month counter (RMONCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded month section of the RTC. The count operation is performed by a carry for each month of the date counter.

The range that can be set is 00–12 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RMONCNT is not initialized by a power-on reset or manual reset, or in standby mode.

14.2.8 Year Counter (RYRCNT)

The year counter (RYRCNT) is an 8-bit readable/writable register used for setting/counting in the BCD-coded year section of the RTC. The least significant 2 digits of the western calendar year are displayed. The count operation is performed by a carry for each year of the month counter.

The range that can be set is 00–99 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RYRCNT is not initialized by a power-on reset or manual reset, or in standby mode.

Leap years are recognized by dividing the year counter value by 4 and obtaining a fractional result of 0.

14.2.9 Second Alarm Register (RSECAR)

The second alarm register (RSECAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded second section counter RSECCNT of the RTC. When the ENB bit is set to 1, a comparison with the RSECCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 00–59 (decimal) + ENB bit. Errant operation will result if any other value is set.

The ENB bit in RSECAR is initialized to 0 by a power-on reset. The remaining RSECAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|----------|-----|-----|------|------|-----|
| | ENB | 1 | 0 second | s | | 1 se | cond | |
| Initial value: | 0 | _ | — | — | _ | — | — | _ |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

14.2.10 Minute Alarm Register (RMINAR)

The minute alarm register (RMINAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded minute section counter RMINCNT of the RTC. When the ENB bit is set to 1, a comparison with the RMINCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 00–59 (decimal) + ENB bit. Errant operation will result if any other value is set.

The ENB bit in RMINAR is initialized by a power-on reset. The remaining RMINAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|------------|-----|-----|------|------|-----|
| | ENB | - | 10 minutes | S | | 1 mi | nute | |
| Initial value: | 0 | | — | — | _ | — | — | _ |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

14.2.11 Hour Alarm Register (RHRAR)

The hour alarm register (RHRAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded hour section counter RHRCNT of the RTC. When the ENB bit is set to 1, a comparison with the RHRCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 00–23 (decimal) + ENB bit. Errant operation will result if any other value is set.

The ENB bit in RHRAR is initialized by a power-on reset. The remaining RHRAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|---|------|------|-----|-----|-----|-----|
| | ENB | — | 10 h | ours | | 1 h | our | |
| Initial value: | 0 | 0 | — | — | — | — | — | _ |
| R/W: | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W |

www.DataSheet4U.com

14.2.12 Day of Week Alarm Register (RWKAR)

The day of week alarm register (RWKAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded day of week section counter RWKCNT of the RTC. When the ENB bit is set to 1, a comparison with the RWKCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 0-6 (decimal) + ENB bit. Errant operation will result if any other value is set.

The ENB bit in RWKAR is initialized by a power-on reset. The remaining RWKAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|---|---|---|---|-----|-----------|-----|
| | ENB | _ | _ | — | | D | ay of wee | k |
| Initial value: | 0 | 0 | 0 | 0 | 0 | — | — | _ |
| R/W: | R/W | R | R | R | R | R/W | R/W | R/W |

Days of the week are coded as shown in table 14.4.

| Table 14.4 | Day-of-Week | Codes | (RWKAR) |
|-------------------|-------------|-------|---------|
|-------------------|-------------|-------|---------|

| Day of Week | Code | |
|-------------|------|--|
| Sunday | 0 | |
| Monday | 1 | |
| Tuesday | 2 | |
| Wednesday | 3 | |
| Thursday | 4 | |
| Friday | 5 | |
| Saturday | 6 | |

14.2.13 Date Alarm Register (RDAYAR)

The date alarm register (RDAYAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded date section counter RDAYCNT of the RTC. When the ENB bit is set to 1, a comparison with the RDAYCNT value is performed. From among the registers RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 01-31 (decimal) + ENB bit. Errant operation will result if any other value is set. The RDAYCNT range that can be set changes with some months and in leap years. Please confirm the correct setting.

The ENB bit in RDAYAR is initialized by a power-on reset. The remaining RDAYAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|---|------|------|-----|-----|-----|-----|
| | ENB | _ | 10 c | days | | 1 c | lay | |
| Initial value: | 0 | 0 | _ | — | — | — | — | _ |
| R/W: | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W |

14.2.14 Month Alarm Register (RMONAR)

The month alarm register (RMONAR) is an 8-bit readable/writable register, and an alarm register corresponding to the BCD-coded month section counter RMONCNT of the RTC. When the ENB bit is set to 1, a comparison with the RMONCNT value is performed. From among the registers RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range that can be set is 01-12 (decimal) + ENB bit. Errant operation will result if any other value is set.

The ENB bit in RMONAR is initialized by a power-on reset. The remaining RMONAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|---|---|--------------|-----|-----|------|-----|
| | ENB | | | 10 months | | 1 m | onth | |
| Initial value: | 0 | 0 | 0 | — | — | — | | _ |
| R/W: | R/W | R | R | R/W | R/W | R/W | R/W | R/W |

www.DataSheet4U.com

14.2.15 RTC Control Register 1 (RCR1)

The RTC control register 1 (RCR1) is an 8-bit readable/writable register that affects carry flags and alarm flags. It also selects whether to generate interrupts for each flag. Because flags are sometimes set after an operand read, do not use this register in read-modify-write processing.

RCR1 is initialized to H'00 by a power-on reset. In a manual reset, all bits are initialized to 0 except for the CF flag, which is undefined. When using the CF flag, it must be initialized beforehand. This register is not initialized in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|---|---|-----|-----|---|---|-----|
| | CF | _ | — | CIE | AIE | | _ | AF |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R/W | R/W | R | R | R/W |

Bit 7—Carry Flag (CF): Status flag that indicates that a carry has occurred. CF is set to 1 when a count-up to R64CNT or RSECCNT occurs. A count register value read at this time cannot be guaranteed; another read is required.

| Bit 7: CF | Description | |
|-----------|---|-----------------|
| 0 | No count up of R64CNT or RSECCNT Clearing condition: When 0 is written to CF | (Initial value) |
| 1 | Count up of R64CNT or RSECCNT Setting condition: When 1 is written to CF | |

Bits 6, 5, 2, and 1—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 4—Carry Interrupt Enable Flag (CIE): When the carry flag (CF) is set to 1, the CIE bit enables interrupts.

| Bit 4: CIE | Description | |
|------------|---|-----------------|
| 0 | A carry interrupt is not generated when the CF flag is set to 1 | (Initial value) |
| 1 | A carry interrupt is generated when the CF flag is set to 1 | |

Bit 3—Alarm Interrupt Enable Flag (AIE): When the alarm flag (AF) is set to 1, the AIE bit allows interrupts.

| Bit 3: A | IE Description |
|----------|---|
| 0 | An alarm interrupt is not generated when the AF flag is set to 1 |
| | (Initial value) |
| 1 | www.DataSheetAh alarm interrupt is generated when the AF flag is set to 1 |

Bit 0—Alarm Flag (AF): The AF flag is set to 1 when the alarm time set in an alarm register (only registers with ENB bit set to 1) matches the clock and calendar time. This flag is cleared to 0 when 0 is written, but holds its previous value when 1 is written.

| Bit 0: AF | Description | |
|-----------|---|--|
| 0 | Clock/calendar and alarm register have not matched sin Clearing condition: When 0 is written to AF | nce last reset to 0 (Initial value) |
| 1 | Setting condition: Clock/calendar and alarm register hat registers with ENB set) st | ve matched (only |

Note: * Contents do not change when 1 is written to AF.

14.2.16 RTC Control Register 2 (RCR2)

The RTC control register 2 (RCR2) is an 8-bit readable/writable register for periodic interrupt control, 30-second adjustment ADJ, divider circuit RESET, and RTC count start/stop control. It is initialized to H'09 by a power-on reset. It is initialized except for RTCEN and START by a manual reset. It is not initialized, and retains its contents, in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|------|------|------|-------|-----|-------|-------|
| | PEF | PES2 | PES1 | PES0 | RTCEN | ADJ | RESET | START |
| Initial value: | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bit 7—Periodic Interrupt Flag (PEF): Indicates interrupt generation with the period designated by the PES bits. When set to 1, PEF generates periodic interrupts.

| Bit 7: PEF | Description | |
|------------|---|---------------------------|
| 0 | Interrupts not generated with the period designated by the PE Clearing condition: When 0 is written to PEF | S bits (Initial value) |
| 1 | Interrupts generated with the period designated by the PES bi Setting condition: When 1 is written to PEF | ts |

| Bit 6: PES2 | Bit 5: PES1 | Bit 4: PES0 | Description |
|-------------|----------------------|-------------|--|
| 0 | 0 | 0 | No periodic interrupts generated (Initial value) |
| | | 1 | Periodic interrupt generated every 1/256 second |
| | 1 DataSheet4U.com | 0 | Periodic interrupt generated every 1/64 second |
| | | 1 | Periodic interrupt generated every 1/16 second |
| 1 | 0 | 0 | Periodic interrupt generated every 1/4 second |
| | | 1 | Periodic interrupt generated every 1/2 second |
| | 1 | 0 | Periodic interrupt generated every 1 second |
| | | 1 | Periodic interrupt generated every 2 seconds |

Bits 6 to 4—Periodic Interrupt Flags (PES2-PES0): Specify the periodic interrupt.

Bit 3—RTCEN: Controls the operation of the crystal oscillator for the RTC.

| Bit 3: RTCEN | Description | |
|--------------|--------------------------------------|-----------------|
| 0 | Crystal oscillator for RTC is halted | |
| 1 | Crystal oscillator for RTC runs | (Initial value) |

Bit 2—30 Second Adjustment (ADJ): When 1 is written to the ADJ bit, times of 29 seconds or less will be rounded to 00 seconds and 30 seconds or more to 1 minute. The divider circuit will be simultaneously reset. This bit is always read as 0. The maximum duration between when the ADJ bit is set to 1 and when the new setting is reflected in the readout value from the seconds counter (RSECCNT) is approximately 91.6 μ s (when a 32.768 kHz quartz oscillator is connected to the EXTAL2 pin).

| Bit 2: ADJ | Description | |
|------------|----------------------|-----------------|
| 0 | Runs normally | (Initial value) |
| 1 (Write) | 30-second adjustment | |

Bit 1—Reset (RESET): When 1 is written, initializes the divider circuit (RTC prescaler and R64CNT). This bit is always read as 0.

| Bit 1: RESET | Description | |
|--------------|--------------------------|-----------------|
| 0 | Runs normally | (Initial value) |
| 1 (Write) | Divider circuit is reset | |

Bit 0—Start Bit (START): Halts and restarts the counter (clock).

| Bit 0: START | Description |
|--------------|---|
| 0 | Second/minute/hour/day/week/month/year counter halts* |
| 1 | Second/minute/hour/day/week/month/year counter runs normally* |
| | (Initial value) |

Note: * The 64-Hz counter always runs unless stopped with the RTCEN bit.

14.3 RTC Operation

14.3.1 Initial Settings of Registers after Power-On

All the registers should be set after the power is turned on.

14.3.2 Setting the Time

Figure 14.2 shows how to set the time when the clock is stopped. This works when the entire calendar or clock is to be set.

Figure 14.2 Setting the Time

14.3.3 Reading the Time

Figure 14.3 shows how to read the time. If a carry occurs while reading the time, the correct time will not be obtained, so it must be read again. Part (a) in figure 14.3 shows the method of reading the time without using interrupts; part (b) in figure 14.3 shows the method using carry interrupts. To keep programming simple, method (a) should normally be used.

www.DataSheet4U.con

Figure 14.3 Reading the Time

www.DataSheet4U.com Rev. 5.0, 09/03, page 467 of 806

14.3.4 Alarm Function

Figure 14.4 shows how to use the alarm function.

Alarms can be generated using seconds, minutes, hours, day of the week, date, month, or any combination of these. Set the ENB bit (bit 7) to 1 in the register to which the alarm applies, and then set the alarm time in the lower bits. Clear the ENB bit to 0 in registers to which the alarm does not apply.

When the clock and alarm times match, 1 is set in the AF bit (bit 0) in RCR1. Alarm detection can be checked by reading this bit, but normally it is done by interrupt. If 1 is placed in the AIE bit (bit 3) in RCR1, an interrupt is generated when an alarm occurs.

Figure 14.4 Using the Alarm Function

14.3.5 Crystal Oscillator Circuit

Crystal oscillator circuit constants (recommended values) are shown in table 14.5, and the RTC crystal oscillator circuit in figure 14.5.

| Table 14.5 | Recommended | Oscillator | Circuit | Constants | (Recommended | Values) |
|-------------------|-------------|------------|---------|-----------|--------------|---------|
|-------------------|-------------|------------|---------|-----------|--------------|---------|

| www.DataSheet4U.com | Cin | Cout |
|---------------------|-------------|-------------|
| 32.768 kHz | 10 to 22 pF | 10 to 22 pF |

Figure 14.5 Example of Crystal Oscillator Circuit Connection

www.DataSheet4U.com Rev. 5.0, 09/03, page 469 of 806

14.4 Usage Notes

14.4.1 Register Writing during RTC Count

The following RTC registers cannot be written to during an RTC count (while bit 0 = 1 in RCR2).

RSECCNT, RMINCNT, RHRCNT, RDAYCNT, RWKCNT, RMONCNT, RYRCNT

The RTC count must be halted before writing to any of the above registers.

14.4.2 Use of Realtime Clock (RTC) Periodic Interrupts

The method of using the periodic interrupt function is shown in figure 14.6.

A periodic interrupt can be generated periodically at the interval set by the periodic interrupt enable flag (PES) in RTC control register 2 (RCR2). When the time set by the periodic interrupt enable flag (PES) has elapsed, the periodic interrupt flag (PEF) is set to 1.

The periodic interrupt flag (PEF) is cleared to 0 upon periodic interrupt generation when the periodic interrupt enable flag (PES) is set. Periodic interrupt generation can be confirmed by reading this bit, but normally the interrupt function is used.

Figure 14.6 Using Periodic Interrupt Function

14.4.3 Precautions when Using RTC Module Standby

Before switching the RTC to module standby, access at least one among the registers RTC, SCI, and TMU.

Section 15 Serial Communication Interface (SCI)

15.1 Overview

The SH7729R has an on-chip serial communication interface (SCI) that supports both asynchronous and clock synchronous serial communication. It also has a multiprocessor communication function for serial communication among two or more processors. The SCI supports a smart card interface, which is a serial communication feature for IC card interfaces that conforms to the ISO/IEC standard 7816-3 for identification cards. See section 16, Smart Card Interface, for more information.

15.1.1 Features

Selection of asynchronous or synchronous as the serial communication mode.

- Asynchronous mode:
 - Serial data communication is synchronized by start-stop in character units. The SCI can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. It can also communicate with two or more other processors using the multiprocessor communication function. There are 12 selectable serial data communication formats.
 - Data length: 7 or 8 bits
 - Stop bit length: 1 or 2 bits
 - Parity: Even, odd, or none
 - Multiprocessor bit: 1 or 0
 - Receive error detection: Parity, overrun, and framing errors
 - Break detection: By reading the RxD level directly from the SC port data register (SCPDR) when a framing error occurs
- Synchronous mode:
 - Serial data communication is synchronized with a clock signal. The SCI can communicate with other chips having a synchronous communication function. There is one serial data communication format.
 - Data length: 8 bits
 - Receive error detection: Overrun errors
- Full duplex communication: The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use double buffering, so continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates

www.DataSheet4U.com Rev. 5.0, 09/03, page 471 of 806

- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK pin (external)
- Four types of interrupts: Transmit-data-empty, transmit-end, receive-data-full, and receiveerror interrupts are requested independently.
- When the SCI is not in use, it can be stopped by halting the clock supplied to it, saving power.

www.DataSheet4U.com

15.1.2 Block Diagram

Figure 15.1 shows a block diagram of the SCI.

Figure 15.1 Block Diagram of SCI

Figures 15.2, 15.3, and 15.4 show block diagrams of the SCI I/O port pins.

SCIF pin I/O and data control is performed by bits 11 to 8 of SCPCR and bits 5 and 4 of SCPDR. For details, see section 15.2.8, SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR).

Figure 15.2 SCPT[1]/SCK0 Pin

www.DataSheet4U.com Rev. 5.0, 09/03, page 473 of 806

Figure 15.3 SCPT[0]/TxD0 Pin

Figure 15.4 SCPT[0]/RxD0 Pin

15.1.3 Pin Configuration

The SCI has the serial pins summarized in table 15.1.

Table 15.1 SCI Pins

| Pin Name | Abbreviation | I/O | Function |
|-------------------|--------------|--------|----------------------|
| Serial clock pin | SCK0 | I/O | Clock I/O |
| Receive data pin | RxD0 | Input | Receive data input |
| Transmit data pin | TxD0 | Output | Transmit data output |

Note: These pins are made to function as serial pins by performing SCI operation settings with the TE, RE, CKEI, and CKEO bits in SCSCR and the C/Ā bit in SCSMR. Break state transmission and detection can be performed by means of the SCI's SCSPTR register.

15.1.4 Register Configuration

Table 15.2 summarizes the SCI internal registers. These registers select the communication mode (asynchronous or synchronous), specify the data format and bit rate, and control the transmitter and receiver sections.

| Name | Abbreviation | R/W | Initial Value | Address | Access size |
|--------------------------|--------------|---------|---------------|--|-------------|
| Serial mode register | SCSMR | R/W | H'00 | H'FFFFFE80 | 8 |
| Bit rate register | SCBRR | R/W | H'FF | H'FFFFFE82 | 8 |
| Serial control register | SCSCR | R/W | H'00 | H'FFFFFE84 | 8 |
| Transmit data register | SCTDR | R/W | H'FF | H'FFFFFE86 | 8 |
| Serial status register | SCSSR | R/(W)*1 | H'84 | H'FFFFFE88 | 8 |
| Receive data register | SCRDR | R | H'00 | H'FFFFFE8A | 8 |
| SC port data register | SCPDR | R/W | H'00 | H'04000136 (H'A4000136) ^{*2} | 8 |
| SC port control register | SCPCR | R/W | H'A888 | H'04000116 (H'A4000116) ^{*2} | 16 |

Table 15.2 SCI Registers

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

- 1. The only value that can be written is 0 to clear the flags.
- 2. When address translation by the MMU does not apply, the address in parentheses should be used.

15.2 Register Descriptions

15.2.1 Receive Shift Register (SCRSR)

The receive shift register (SCRSR) receives serial data. Data input at the RxD pin is loaded into SCRSR in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to SCRDR. The CPU cannot read or write to SCRSR directly.

15.2.2 Receive Data Register (SCRDR)

The receive data register (SCRDR) stores serial receive data. The SCI completes the reception of one byte of serial data by moving the received data from the receive shift register (SCRSR) into SCRDR for storage. SCRSR is then ready to receive the next data. This double buffering allows the SCI to receive data continuously.

The CPU can read but not write to SCRDR. SCRDR is initialized to H'00 by a reset and in standby or module standby mode.

15.2.3 Transmit Shift Register (SCTSR)

The transmit shift register (SCTSR) transmits serial data. The SCI loads transmit data from the transmit data register (SCTDR) into SCTSR, then transmits the data serially from the TxD pin, LSB (bit 0) first. After transmitting one-byte data, the SCI automatically loads the next transmit data from SCTDR into SCTSR and starts transmitting again. If the TDRE bit in SCSSR is 1, however, the SCI does not load the SCTDR contents into SCTSR. The CPU cannot read or write to SCTSR directly.

15.2.4 Transmit Data Register (SCTDR)

The transmit data register (SCTDR) is an 8-bit register that stores data for serial transmission. When the SCI detects that the transmit shift register (SCTSR) is empty, it moves transmit data written in SCTDR into SCTSR and starts serial transmission. Continuous serial transmission is possible by writing the next transmit data in SCTDR during serial transmission from SCTSR.

The CPU can always read and write to SCTDR. SCTDR is initialized to H'FF by a reset and in standby or module standby mode.

15.2.5 Serial Mode Register (SCSMR)

The serial mode register (SCSMR) is an 8-bit register that specifies the SCI serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to SCSMR. SCSMR is initialized to H'00 by a reset and in standby or module standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|-----|-----|------|-----|------|------|
| | C/Ā | CHR | PE | O/E | STOP | MP | CKS1 | CKS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bit 7—Communication Mode (C/\overline{A}) : Selects whether the SCI operates in asynchronous or synchronous mode.

Bit 7: C/A Description

| 0 | Asynchronous mode | (Initial value) |
|---|-------------------|-----------------|
| 1 | Synchronous mode | |

Bit 6—Character Length (CHR): Selects 7-bit or 8-bit data in asynchronous mode. In the synchronous mode, the data length is always eight bits, regardless of the CHR setting.

| Bit 6 | : CHR | Description | |
|-------|----------|--|---|
| 0 | | 8-bit data | (Initial value) |
| 1 | www.Data | 7-bit data Sheet4U.com When 7-bit data is selected, the MSB (bit transmitted. | 7) of the transmit data register is not |

Bit 5—Parity Enable (PE): Selects whether to add a parity bit to transmit data and to check the parity of receive data, in asynchronous mode. In synchronous mode, a parity bit is neither added nor checked, regardless of the PE setting.

| Bit 5: PE | Description | |
|-----------|--|-----------------|
| 0 | Parity bit not added or checked | (Initial value) |
| 1 | Parity bit added and checked | |
| | When PE is set to 1, an even or odd parity bit is added to transmit depending on the parity mode (O/\overline{E}) setting. Receive data parity is according to the even/odd (O/\overline{E}) mode setting. | |

Bit 4—Parity Mode (O/ \overline{E}): Selects even or odd parity when parity bits are added and checked. The O/ \overline{E} setting is used only in asynchronous mode and only when the parity enable bit (PE) is set to 1 to enable parity addition and checking. The O/ \overline{E} setting is ignored in synchronous mode, or in asynchronous mode when parity addition and checking is disabled.

| Bit 4: O/E | Description | | | | |
|------------|---|-----------------|--|--|--|
| 0 | Even parity | (Initial value) | | | |
| | If even parity is selected, the parity bit is added to transmit data to make an number of 1s in the transmitted character and parity bit combined. Receive c is checked to see if it has an even number of 1s in the received character ar parity bit combined. | | | | |
| 1 | Odd parity | | | | |
| | If odd parity is selected, the parity bit is added to transmit data to m number of 1s in the transmitted character and parity bit combined. is checked to see if it has an odd number of 1s in the received char parity bit combined. | Receive data | | | |

Bit 3—Stop Bit Length (STOP): Selects one or two bits as the stop bit length in asynchronous mode. This setting is used only in asynchronous mode. It is ignored in synchronous mode because no stop bits are added.

When receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit, but if the second stop bit is 0, it is treated as the start bit of the next incoming character.

| Bit 3: STOP | Description | |
|-----------------|---|--------------------|
| 0 | One stop bit | (Initial value) |
| | When transmitting, a single 1-bit is added at the end of each tran character. | nsmitted |
| 1 Two stop bits | | |
| | When transmitting, two 1-bits are added at the end of each trans | smitted character. |

Bit 2—Multiprocessor Mode (MP): Selects multiprocessor format. When multiprocessor format is selected, settings of the parity enable (PE) and parity mode (O/\overline{E}) bits are ignored. The MP bit setting is used only in asynchronous mode; it is ignored in synchronous mode. For the multiprocessor communication function, see section 15.3.3, Multiprocessor Communication.

| Bit 2: MP | Description | |
|-----------|----------------------------------|-----------------|
| 0 | Multiprocessor function disabled | (Initial value) |
| 1 | Multiprocessor format selected | |

Bits 1 and 0—Clock Select 1 and 0 (CKS1, CKS0): Select the internal clock source of the onchip baud rate generator. Four clock sources are available. P ϕ , P ϕ /4, P ϕ /16, and P ϕ /64. For further information on the clock source, bit rate register settings, and baud rate, see section 15.2.9, Bit Rate Register (SCBRR).

| Bit 1: CKS1 | Bit 0: CKS0 | Description | |
|-------------|-------------|-------------|-----------------|
| 0 | 0 | Ρφ | (Initial value) |
| | 1 | Ρφ/4 | |
| 1 | 0 | Ρφ/16 | |
| | 1 | Ρφ/64 | |

Note: Po: Peripheral clock

15.2.6 Serial Control Register (SCSCR)

The serial control register (SCSCR) operates the SCI transmitter/receiver, selects the serial clock output in asynchronous mode, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write to SCSCR. SCSCR is initialized to H'00 by a reset and in standby or module standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|-----|-----|------|------|------|------|
| | TIE | RIE | TE | RE | MPIE | TEIE | CKE1 | CKE0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Bit 7—Transmit Interrupt Enable (TIE): Enables or disables the transmit-data-empty interrupt (TXI) requested when the transmit data register empty bit (TDRE) in the serial status register (SCSSR) is set to 1 due to transfer of serial transmit data from SCTDR to SCTSR.

| Bit 7: TIE | Description | | | |
|------------|--|--|--|--|
| 0 | Transmit-data-empty interrupt request (TXI) is disabled (Initial value) | | | |
| | The TXI interrupt request can be cleared by reading TDRE after it has been set to 1, then clearing TDRE to 0, or by clearing TIE to 0. | | | |
| 1 | Transmit-data-empty interrupt request (TXI) is enabled | | | |

Bit 6—Receive Interrupt Enable (RIE): Enables or disables the receive-data-full interrupt (RXI) requested when the receive data register full bit (RDRF) in the serial status register (SCSSR) is set to 1 due to transfer of serial receive data from SCRSR to SCRDR. It also enables or disables receive-error interrupt (ERI) requests.

| Bit 6: RIE 0 | Description Receive-data-full interrupt (RXI) and receive-error interrupt (ERI) requests are disabled | | | | |
|------------------------|---|--|--|--|--|
| | | | | | |
| | 1 | Receive-data-full interrupt (RXI) and receive-error interrupt (ERI) requests are enabled | | | |

Bit 5—Transmit Enable (TE): Enables or disables the SCI serial transmitter.

| Bit 5: TE | Description | |
|-----------|---|-----------------------------|
| 0 | Transmitter disabled | (Initial value) |
| | The transmit data register empty bit (TDRE) in the serial is fixed at 1. | status register (SCSSR) |
| 1 www.Da | Transmitter enabled | |
| | Serial transmission starts when the transmit data register serial status register (SCSSR) is cleared to 0 after writing SCTDR. Select the transmit format in SCSMR before set | g of transmit data into the |

Bit 4—Receive Enable (RE): Enables or disables the SCI serial receiver.

| Bit 4: RE | Description | |
|-----------|---|--------|
| 0 | Receiver disabled (Initial v | /alue) |
| | Clearing RE to 0 does not affect the receive flags (RDRF, FER, PER, OREI These flags retain their previous values. | R). |
| 1 | Receiver enabled | |
| | Serial reception starts when a start bit is detected in asynchronous mode, or synchronous clock input is detected in synchronous mode. Select the receive format in SCSMR before setting RE to 1. | |

Bit 3—Multiprocessor Interrupt Enable (MPIE): Enables or disables multiprocessor interrupts. The MPIE setting is used only in asynchronous mode, and only if the multiprocessor mode bit (MP) in the serial mode register (SCSMR) is set to 1 during reception. The MPIE setting is ignored in synchronous mode or when the MP bit is cleared to 0.

| Bit 3: MPIE | Description |
|-------------|--|
| 0 | Multiprocessor interrupts are disabled (normal receive operation) (Initial value) |
| | MPE is cleared to 0 when MPIE is cleared to 0, or the multiprocessor bit (MPB) is set to 1 in receive data. |
| 1 | Multiprocessor interrupts are enabled |
| | Receive-data-full interrupt requests (RXI), receive-error interrupt requests (ERI), and setting of the RDRF, FER, and ORER status flags in the serial status register (SCSSR) are disabled until data with a multiprocessor bit of 1 is received. |
| | The SCI does not transfer receive data from SCRSR to SCRDR, does not detect receive errors, and does not set the RDRF, FER, and ORER flags in the serial status register (SCSSR). When it receives data that includes MPB = 1, the SCSSR's MPB flag is set to 1, and the SCI automatically clears MPIE to 0, generates RXI and ERI interrupts (if the TIE and RIE bits in the SCSCR are set to 1), and allows the FER and ORER bits to be set. |

Bit 2—Transmit-End Interrupt Enable (TEIE): Enables or disables the transmit-end interrupt (TEI) requested if SCTDR does not contain new transmit data when the MSB is transmitted.

| Bit 2: TE | IE Description |
|-----------|---|
| 0 | Transmit-end interrupt (TEI) requests are disabled* (Initial value) |
| 1 | Transmit-end interrupt (TEI) requests are enabled* |
| (| The TEI request can be cleared by reading the TDRE bit in the serial status register SCSSR) after it has been set to 1, then clearing TDRE to 0 and clearing the transmit end TEND) bit to 0, or by clearing the TEIE bit to 0. |

Bits 1 and 0—Clock Enable 1 and 0 (CKE1, CKE0): Select the SCI clock source and enable or disable clock output from the SCK pin. Depending on the combination of CKE1 and CKE0, the SCK pin can be used for serial clock output or serial clock input.

The CKE0 setting is valid only in asynchronous mode, and only when the SCI is internally clocked (CKE1 = 0). The CKE0 setting is ignored in synchronous mode, or when an external clock source is selected (CKE1 = 1). Before selecting the SCI operating mode in the serial mode register (SCSMR), set CKE1 and CKE0. For further details on selection of the SCI clock source, see table 15.10 in section 15.3, Operation.

| Bit 1: CKE1 | Bit 0: CKE0 | Description | |
|----------------|----------------|-------------------|---|
| 0 | 0 | Asynchronous mode | Internal clock, SCK pin used for input pin (input signal is ignored) (Initial value) |
| | | Synchronous mode | Internal clock, SCK pin used for serial clock output (Initial value) |
| | 1 | Asynchronous mode | Internal clock, SCK pin used for clock output*1 |
| | | Synchronous mode | Internal clock, SCK pin used for serial clock output |
| 1 | 0 | Asynchronous mode | External clock, SCK pin used for clock input*2 |
| | | Synchronous mode | External clock, SCK pin used for serial clock input |
| | 1 | Asynchronous mode | External clock, SCK pin used for clock input ^{*2} |
| | | Synchronous mode | External clock, SCK pin used for serial clock input |

Notes: 1. The output clock frequency is the same as the bit rate.

2. The input clock frequency is 16 times the bit rate.

15.2.7 Serial Status Register (SCSSR)

The serial status register (SCSSR) is an 8-bit register containing multiprocessor bit values, and status flags that indicate the SCI operating state.

The CPU can always read and write to SCSSR, but cannot write 1 to the status flags (TDRE, RDRF, ORER, PER, and FER). These flags can be cleared to 0 only if they have first been read (after being set to 1). Bits 2 (TEND) and 1 (MPB) are read-only bits that cannot be written. SCSSR is initialized to H'84 by a reset and in standby or module standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|--------|--------|--------|--------|--------|------|-----|------|
| | TDRE | RDRF | ORER | FER | PER | TEND | MPB | MPBT |
| Initial value: | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| R/W: | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R | R | R/W |
| to: * The only value that can be written is 0 to clear the flag | | | | | | | | |

Note: * The only value that can be written is 0 to clear the flag.

Bit 7—Transmit Data Register Empty (TDRE): Indicates that the SCI has loaded transmit data from SCTDR into SCTSR and new serial transmit data can be written in SCTDR.

| Bit 7: TDRE | Description | |
|-------------|--|-----------------------|
| 0 | SCTDR contains valid transmit data | |
| | TDRE is cleared to 0 when software reads TDRE after it has writes 0 in TDRE or data is written in SCTDR. | s been set to 1, then |
| 1 | SCTDR does not contain valid transmit data | (Initial value) |
| | TDRE is set to 1 when the chip is reset or enters standby mode, the TE to serial control register (SCSCR) is cleared to 0, or SCTDR contents are lo into SCTSR, so new data can be written in SCTDR. | |

Bit 6-Receive Data Register Full (RDRF): Indicates that SCRDR contains received data.

| Bit 6: | RDRF | Description | |
|--------|------|---|------------------|
| 0 | | SCRDR does not contain valid receive data | (Initial value) |
| | | RDRF is cleared to 0 when the chip is reset or enters stand reads RDRF after it has been set to 1, then writes 0 in RDR | • |
| 1 | | SCRDR contains valid receive data | |
| | | RDRF is set to 1 when serial data is received normally and sCRSR to SCRDR. | transferred from |
| Note: | | and RDRF are not affected by detection of receive errors or b n the serial control register. They retain their previous contents | |

bit to 0 in the serial control register. They retain their previous contents. If RDRF is still set to 1 when reception of the next data ends, an overrun error (ORER) occurs and the receive data is lost.

Bit 5—Overrun Error (ORER): Indicates that data reception aborted due to an overrun error.

| Bit 5: ORER | Description | |
|----------------|--|------------------|
| 0 | Receiving is in progress or has ended normally ^{*1} | (Initial value) |
| | ORER is cleared to 0 when the chip is reset or enters standby mo software reads ORER after it has been set to 1, then writes 0 to 0 | , |
| 1 www.Datas | A receive overrun error occurred ^{*2} | |
| | ORER is set to 1 if reception of the next serial data ends when RE | DRF is set to 1. |
| Notes: 1. Clea | ring the RE bit to 0 in the serial control register does not affect the C | DRER bit, which |

retains its previous value.

2. SCRDR continues to hold the data received before the overrun error, so subsequent receive data is lost. Serial receiving cannot continue while ORER is set to 1. In synchronous mode, serial transmitting is also disabled.

Bit 4—Framing Error (FER): Indicates that data reception aborted due to a framing error in asynchronous mode.

| Bit 4: FER | Description | | | |
|------------|---|--|--|--|
| 0 | Receiving is in progress or has ended normally (Initial value) | | | |
| | Clearing the RE bit to 0 in the serial control register does not affect the FER bit, which retains its previous value. | | | |
| | FER is cleared to 0 when the chip is reset or enters standby mode, or when software reads FER after it has been set to 1, then writes 0 to FER. | | | |
| 1 | A receive framing error occurred | | | |
| | When the stop bit length is two bits, only the first bit is checked. The second stop bit is not checked. When a framing error occurs, the SCI transfers the receive data into SCRDR but does not set RDRF. Serial receiving cannot continue while FER is set to 1. In synchronous mode, serial transmitting is also disabled. | | | |
| | FER is set to 1 if the stop bit at the end of receive data is checked and found to be 0. | | | |

Bit 3—Parity Error (PER): Indicates that data reception (with parity) aborted due to a parity error in asynchronous mode.

| Bit 3: PER | Description |
|------------|---|
| 0 | Receiving is in progress or has ended normally (Initial value) |
| | Clearing the RE bit to 0 in the serial control register does not affect the PER bit, ^{v.DataS} which retains its previous value. |
| | PER is cleared to 0 when the chip is reset or enters standby mode, or when software reads PER after it has been set to 1, then writes 0 to PER. |
| 1 | A receive parity error occurred |
| | When a parity error occurs, the SCI transfers the receive data into SCRDR but does not set RDRF. Serial receiving cannot continue while PER is set to 1. In synchronous mode, serial transmitting is also disabled. |
| | PER is set to 1 if the number of 1s in receive data, including the parity bit, does not match the even or odd parity setting of the parity mode bit (O/\overline{E}) in the serial mode register (SCSMR). |

Bit 2—Transmit End (TEND): Indicates that when the last bit of a serial character was transmitted, SCTDR did not contain valid data, so transmission has ended. TEND is a read-only bit and cannot be written to.

| Bit 2: TEND | Description | |
|-------------|---|---------------------|
| 0 | Transmission is in progress | |
| | TEND is cleared to 0 when software reads TDRE after it has writes 0 to TDRE. | been set to 1, then |
| 1 | End of transmission | (Initial value) |
| | TEND is set to 1 when the chip is reset or enters standby more cleared to 0 in the serial control register (SCSCR), or if TDRE bit of a one-byte serial character is transmitted. | , |

Bit 1—Multiprocessor Bit (MPB): Stores the value of the multiprocessor bit in receive data when a multiprocessor format is selected for receiving in asynchronous mode. MPB is a read-only bit and cannot be written to.

| Bit 1: MPB | Description | | | |
|------------|---|-----------------|--|--|
| 0 | Multiprocessor bit value in receive data is 0 | (Initial value) | | |
| | If RE is cleared to 0 when a multiprocessor format is selected, MPB retains its previous value. | | | |
| 1 | Multiprocessor bit value in receive data is 1 | | | |

Bit 0—Multiprocessor Bit Transfer (MPBT): Stores the value of the multiprocessor bit added to transmit data when a multiprocessor format is selected for transmitting in asynchronous mode. The MPBT setting is ignored in synchronous mode, when a multiprocessor format is not selected, or when the SCI is not transmitting.

| Bit 0 | : MPBT | Description | |
|-------|-----------|--|-----------------|
| 0 | www.DataS | Multiprocessor bit value in transmit data is 0 | (Initial value) |
| 1 | | Multiprocessor bit value in transmit data is 1 | |

15.2.8 SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR)

The SC port control register (SCPCR) and SC port data register (SCPDR) control I/O and data for the port pins multiplexed with the serial communication interface (SCI) pins.

SCPCR settings are used to perform I/O control, to enable data written in SCPDR to be output to the TxD pin, and input data to be read from the RxD pin, and to control serial transmission/reception breaks.

It is also possible to read data on the SCK pin, and write output data.

SCPCR

| | | | | | | | | | | | | | | | | |

SCI pin I/O and data control are performed by bits 3–0 of SCPCR and bits 1 and 0 of SCPDR.

www.DataSheet4U.com Rev. 5.0, 09/03, page 487 of 806

SCPCR Bits 3 and 2—Serial Clock Port I/O (SCP1MD1, SCP1MD0): Specify serial port SCK pin I/O. When the SCK pin is actually used as a port I/O pin, clear the C/\overline{A} bit in SCSMR and bits CKE1 and CKE0 in SCSCR to 0.

| Bit 3: SCP1 | | Description | | | | | |
|----------------|--------------------|---|--|--|--|--|--|
| 0 | www.Datameet4U.com | SCP1DT bit value is not output to SCK pin | | | | | |
| 0 | 1 | SCP1DT bit value is output to SCK pin | | | | | |
| 1 | 0 | SCK pin value is read from SCP1DT bit | | | | | |
| 1 | 1 | (Initial values: 1 and 0) | | | | | |

SCPDR Bit 1—Serial Clock Port Data (SCP1DT): Specifies the serial port SCK pin I/O data. Input or output is specified by the SCP1MD0 and SCP1MD1 bits. In output mode, the value of the SCP1DT bit is output to the SCK pin. In output mode, the SCK pin value is read from the SCP1DT bit.

| Bit 1: SCP1DT | Description | |
|------------------|------------------|-----------------|
| 0 | I/O data is low | (Initial value) |
| 1 | I/O data is high | |

SCPCR Bits 1 and 0—Serial Port Break I/O (SCP0MD1, SCP0MD0): Specify the serial port TxD pin output condition. When the TxD pin is actually used as a port output pin and outputs the value set with the SCP0DT bit, clear the TE bit in SCSCR to 0.

| Bit 1: SCP0MD1 | Bit 0: SCP0MD0 | Description | |
|-------------------|-------------------|---|-----------------|
| 0 | 0 | SCP0DT bit value is not output to TxD pin | (Initial value) |
| 0 | 1 | SCP0DT bit value is output to TxD pin | |

www.DataSheet4U.com

SCPDR Bit 0—Serial Port Break Data (SCP0DT): Specifies the serial port RxD pin input data and TxD pin output data. The TxD pin output condition is specified by the SCP0MD0 and SCP0MD1 bits. When the TxD pin is set to output mode, the value of the SCP0DT bit is output to the TxD pin. The RxD pin value is read from the SCP0DT bit regardless of the values of the SCP0MD0 and SCP0MD0 and SCP0MD1 bits, if RE in SCSCR is set to 1. The initial value of this bit after a power-on reset is undefined.

www.DataSheet4U.com

| Bit 0: SCP0DT | Description | |
|------------------|------------------|-----------------|
| 0 | I/O data is low | (Initial value) |
| 1 | I/O data is high | |

Block diagrams of the SCI I/O port pins are shown in figures 15.2, 15.3, and 15.4.

15.2.9 Bit Rate Register (SCBRR)

The bit rate register (SCBRR) is an 8-bit register that, together with the baud rate generator clock source selected by the CKS1 and CKS0 bits in the serial mode register (SCSMR), determines the serial transmit/receive bit rate.

The CPU can always read and write to SCBRR. SCBRR is initialized to H'FF by a reset, and in module standby or standby mode. Each channel has independent baud rate generator control, so different values can be set in two channels.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|
| | | | | | | | | |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W |

The SCBRR setting is calculated as follows:

Asynchronous mode: N = $\frac{P\varphi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$

Synchronous mode: N = $\frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$

- B: Bit rate (bits/s)
- N: SCBRR setting for baud rate generator ($0 \le N \le 255$)
- Po: Operating frequency for peripheral modules (MHz)

n: Baud rate generator clock source (n = 0, 1, 2, 3) (for the clock sources and values of n, see table 15.3.)

www.DataSheet4U.com

Rev. 5.0, 09/03, page 489 of 806

Table 15.3SCSMR Settings

| | | SCSMR Settings | | | | | | |
|---|--------------|----------------|------|--|--|--|--|--|
| n | Clock Source | CKS1 | CKS0 | | | | | |
| 0 | Рф | 0 | 0 | | | | | |
| 1 | | 0 | 1 | | | | | |
| 2 | Ρφ/16 | 1 | 0 | | | | | |
| 3 | Ρφ/64 | 1 | 1 | | | | | |

Note: The bit rate error in asynchronous is given by the following formula:

Error (%) =
$$(\frac{P\phi \times 10^{6}}{(N+1) \times B \times 64 \times 2^{2n-1}}) \times 100$$

Table 15.4 lists examples of SCBRR settings in asynchronous mode, and table 15.5 lists examples of SCBRR settings in synchronous mode.

15.3 Operation

15.3.1 Overview

For serial communication, the SCI has an asynchronous mode in which characters are synchronized individually, and a synchronous mode in which communication is synchronized with clock pulses. Asynchronous/synchronous mode and the transmission format are selected in the serial mode register (SCSMR), as shown in table 15.9. The SCI clock source is selected by the combination of the C/A bit in the serial mode register (SCSMR) and the CKE1 and CKE0 bits in the serial control register (SCSCR), as shown in table 15.10.

Asynchronous Mode:

- Data length is selectable: 7 or 8 bits.
- Parity and multiprocessor bits are selectable. So is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors (FER), parity errors (PER), overrun errors (ORER) and breaks.
- An internal or external clock can be selected as the SCI clock source.
 - When an internal clock is selected, the SCI operates using the on-chip baud rate generator, and can output a serial clock signal with a frequency matching the bit rate.
 - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

Synchronous Mode:

- The transmission/reception format has a fixed 8-bit data length.
- In receiving, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the SCI clock source.
 - When an internal clock is selected, the SCI operates using the on-chip baud rate generator, and outputs a serial clock signal to external devices.
 - When an external clock is selected, the SCI operates on the input serial clock. The on-chip baud rate generator is not used.

15.3.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCI are independent, so full duplex communication is possible. The transmitter and receiver are both double buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 15.5 shows the general format of asynchronous serial communication. In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCI monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCI synchronizes at the falling edge of the start bit. The SCI samples each data bit on the eighth pulse of a clock with a frequency 16 times the bit rate. Receive data is latched at the center of each bit.

Figure 15.5 Example of Data Format in Asynchronous Communication (8-Bit Data with Parity and Two Stop Bits)

Transmit/Receive Formats: Table 15.11 lists the 12 communication formats that can be selected in asynchronous mode. The format is selected by settings in the serial mode register (SCSMR).

 Table 15.11
 Serial Communication Formats (Asynchronous Mode)

— : Don't care bits

START: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multiprocessor bit

Clock: An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCI transmit/receive clock. The clock source is selected by the C/\overline{A} bit in the serial mode register (SCSMR) and bits CKE1 and CKE0 in the serial control register (SCSCR) (table 15.10).

When an external clock is input at the SCK pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCI operates on an internal clock, it can output a clock signal at the SCK pin. The frequency of this output clock is equal to the bit rate. The phase is aligned as in figure 15.6 so that the rising edge of the clock occurs at the center of each transmit data bit.

Figure 15.6 Output Clock and Serial Data Timing (Asynchronous Mode)

Transmitting and Receiving Data (SCI Initialization (Asynchronous Mode)): Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCI as follows.

When changing the operation mode or communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 sets TDRE to 1 and initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags or receive data register (SCRDR), which retain their previous contents.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCI operation becomes unreliable if the clock is stopped.

Figure 15.7 shows a sample flowchart for initializing the SCI. The procedure for initializing the SCI is:

- 1. Select the clock source in the serial control register (SCSCR). Leave RIE, TIE, TEIE, MPIE, TE, and RE cleared to 0. If clock output is selected in asynchronous mode, clock output starts immediately after the setting is made in SCSCR.
- 2. Select the communication format in the serial mode register (SCSMR).
- 3. Write the value corresponding to the bit rate in the bit rate register (SCBRR) (not necessary if an external clock is used).
- 4. Wait for at least the interval required to transmit or receive one bit, then set TE or RE in the serial control register (SCSCR) to 1. Also set RIE, TIE, TEIE, and MPIE as necessary. Setting TE or RE enables the SCI to use the TxD or RxD pin. The initial state is the mark state when transmitting, or the idle state (waiting for a start bit) when receiving.

www.DataSheet4U.com Rev. 5.0, 09/03, page 501 of 806

Figure 15.7 Sample Flowchart for SCI Initialization

Transmitting Serial Data (Asynchronous Mode): Figure 15.8 shows a sample flowchart for transmitting serial data. The procedure for transmitting serial data is:

- 1. SCI status check and transmit data write: Read the serial status register (SCSSR), check that the TDRE bit is 1, then write transmit data in the transmit data register (SCTDR) and clear TDRE to 0.
- 2. To continue transmitting serial data: Read the TDRE bit to check whether it is safe to write (if it reads 1); if so, write data in SCTDR, then clear TDRE to 0.
- 3. To output a break at the end of serial transmission: Set the port SC data register (SCPDR) and port SC control register (SCPCR), then clear the TE bit to 0 in the serial control register (SCSCR). For SCPCR and SCPDR settings, see section 15.2.8, SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR).

Figure 15.8 Sample Flowchart for Transmitting Serial Data

In transmitting serial data, the SCI operates as follows:

- 1. The SCI monitors the TDRE bit in SCSSR. When TDRE is cleared to 0, the SCI recognizes that the transmit data register (SCTDR) contains new data, and loads this data from SCTDR into the transmit shift register (SCTSR).
- 2. After loading the data from SCTDR into SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) is set to 1 in SCSCR, the SCI requests a transmit-data-empty interrupt (TXI) at this time. Serial transmit data is transmitted in the following order from the TxD pin:
 - a. Start bit: One 0 bit is output.
 - b. Transmit data: Seven or eight bits of data are output, LSB first.
 - c. Parity bit or multiprocessor bit: One parity bit (even or odd parity) or one multiprocessor bit is output. Formats in which neither a parity bit nor a multiprocessor bit is output can also be selected.
 - d. Stop bit: One or two 1-bits (stop bits) are output.
 - e. Marking: Output of 1-bits continues until the start bit of the next transmit data.
- 3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads new data from SCTDR into SCTSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit to 1 in SCSSR, outputs the stop bit, then continues output of 1-bits (marking). If the transmit-end interrupt enable bit (TEIE) in SCSCR is set to 1, a transmit-end interrupt (TEI) is requested.

Figure 15.9 Example of SCI Transmit Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit)

Receiving Serial Data (Asynchronous Mode): Figure 15.10 shows a sample flowchart for receiving serial data. The procedure for receiving serial data after enabling the SCI for reception is:

- 1. Receive error handling and break detection: If a receive error occurs, read the ORER, PER and FER bits in SCSSR to identify the error. After executing the necessary error handling, clear ORER, PER and FER to 0. Receiving cannot resume if ORER, PER or FER remains set to 1. When a framing error occurs, the RxD pin can be read to detect the break state.
- 2. SCI status check and receive-data read: Read the serial status register (SCSSR), check that RDRF is set to 1, then read receive data from the receive data register (SCRDR) and clear RDRF to 0. The RXI interrupt can also be used to determine if the RDRF bit has changed from 0 to 1.
- 3. To continue receiving serial data: Read the RDRF and SCRDR bits and clear RDRF to 0 before the stop bit of the current frame is received.

www.DataSheet4U.com Rev. 5.0, 09/03, page 505 of 806

Figure 15.10 Sample Flowchart for Receiving Serial Data

Figure 15.10 Sample Flowchart for Receiving Serial Data (cont)

In receiving, the SCI operates as follows:

- 1. The SCI monitors the communication line. When it detects a start bit (0), the SCI synchronizes internally and starts receiving.
- 2. Receive data is shifted into SCRSR in order from the LSB to the MSB.
- 3. The parity bit and stop bit are received. After receiving these bits, the SCI makes the following checks:
 - a. Parity check: The number of 1s in the receive data must match the even or odd parity setting of the O/\overline{E} bit in SCSMR.
 - b. Stop bit check: The stop bit value must be 1. If there are two stop bits, only the first stop bit is checked.
 - c. Status check: RDRF must be 0 so that receive data can be loaded from SCRSR into SCRDR.

If these checks all pass, the SCI sets RDRF to 1 and stores the received data in SCRDR. If one of the checks fails (receive error), the SCI operates as indicated in table 15.12.

- Note: When a receive error flag is set, further receiving is disabled. The RDRF bit is not set to 1. Be sure to clear the error flags.
- 4. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in SCSCR, the SCI requests a receive-data-full interrupt (RXI). If one of the error flags (ORER, PER, or FER) is set to 1 and the receive-data-full interrupt enable bit (RIE) in SCSCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

Table 15.12 Receive Error Conditions and SCI Operation

| Receive Error | Abbreviation | Condition | Data Transfer |
|----------------------|--------------|--|--|
| Overrun error | ORER | Receiving of next data ends while RDRF is still set to 1 in SCSSR | Receive data not loaded from SCRSR into SCRDR |
| Framing error | FER | Stop bit is 0 | Receive data loaded from SCRSR into SCRDR |
| Parity error | PER | Parity of receive data differs from even/odd parity setting in SCSMR | Receive data loaded from SCRSR into SCRDR |

Figure 15.11 shows an example of SCI receive operation in asynchronous mode.

15.3.3 Multiprocessor Communication

The multiprocessor communication function enables several processors to share a single serial communication line. The processors communicate in asynchronous mode using a format with an additional multiprocessor bit (multiprocessor format).

In multiprocessor communication, each receiving processor is addressed by a unique ID. A serial communication cycle consists of an ID-sending cycle that identifies the receiving processor, and a data-sending cycle. The multiprocessor bit distinguishes ID-sending cycles from data-sending cycles. The transmitting processor starts by sending the ID of the receiving processor with which it wants to communicate as data with the multiprocessor bit set to 1. Next the transmitting processor sends transmit data with the multiprocessor bit cleared to 0.

Receiving processors skip incoming data until they receive data with the multiprocessor bit set to 1. When they receive data with the multiprocessor bit set to 1, receiving processors compare the data with their IDs. The receiving processor with a matching ID continues to receive further incoming data. Processors with IDs not matching the received data skip further incoming data until they again receive data with the multiprocessor bit set to 1. Multiple processors can send and receive data in this way.

Figure 15.12 shows an example of communication among processors using the multiprocessor format.

www.DataSheet4U.com Rev. 5.0, 09/03, page 509 of 806

Figure 15.12 Communication Among Processors Using Multiprocessor Format (Sending Data H'AA to Receiving Processor A)

Communication Formats: Four formats are available. Parity-bit settings are ignored when the multiprocessor format is selected. For details see table 15.11.

Clock: See the description in the asynchronous mode section.

Transmitting Multiprocessor Serial Data: Figure 15.13 shows a sample flowchart for transmitting multiprocessor serial data. The procedure for transmitting multiprocessor serial data is:

- 1. SCI status check and transmit data write: Read the serial status register (SCSSR), check that the TDRE bit is 1, then write transmit data in the transmit data register (SCTDR). Also set MPBT (multiprocessor bit transfer) to 0 or 1 in SCSSR. Finally, clear TDRE to 0.
- 2. To continue transmitting serial data: Read the TDRE bit to check whether it is safe to write (if it reads 1); if so, write data in SCTDR, then clear TDRE to 0.
- 3. To output a break at the end of serial transmission: Set the port SC data register (SCPDR) and port SC control register (SCPCR), then clear the TE bit to 0 in the serial control register (SCSCR). For SCPCR and SCPDR settings, see section 15.2.8, SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR).

Figure 15.13 Sample Flowchart for Transmitting Multiprocessor Serial Data

In transmitting serial data, the SCI operates as follows:

- 1. The SCI monitors the TDRE bit in SCSSR. When TDRE is cleared to 0 the SCI recognizes that the transmit data register (SCTDR) contains new data, and loads this data from SCTDR into the transmit shift register (SCTSR).
- 2. After loading the data from SCTDR into SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in SCSCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time. Serial transmit data is transmitted in the following order from the TxD pin:
 - a. Start bit: One 0-bit is output.
 - b. Transmit data: Seven or eight bits are output, LSB first.
 - c. Multiprocessor bit: One multiprocessor bit (MPBT value) is output.
 - d. Stop bit: One or two 1-bits (stop bits) are output.
 - e. Marking: Output of 1-bits continues until the start bit of the next transmit data.
- 3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads data from SCTDR into SCTSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in SCSSR to 1, outputs the stop bit, then continues output of 1 bits in the mark state. If the transmit-end interrupt enable bit (TEIE) in SCSCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.

Figure 15.14 Example of SCI Multiprocessor Transmit Operation (8-Bit Data with Multiprocessor Bit and One Stop Bit)

www.DataSheet4U.com

Receiving Multiprocessor Serial Data: Figure 15.15 shows a sample flowchart for receiving multiprocessor serial data. The procedure for receiving multiprocessor serial data is:

- 1. ID receive cycle: Set the MPIE bit in the serial control register (SCSCR) to 1.
- 2. SCI status check and compare to ID reception: Read the serial status register (SCSSR), check that RDRF is set to 1, then read data from the receive data register (SCRDR) and compare with the processor's own ID. If the ID does not match the receive data, set MPIE to 1 again and clear RDRF to 0. If the ID matches the receive data, clear RDRF to 0.
- 3. SCI status check and data receiving: Read SCSSR, check that RDRF is set to 1, then read data from the receive data register (SCRDR).
- 4. Receive error handling and break detection: If a receive error occurs, read the ORER and FER bits in SCSSR to identify the error. After executing the necessary error handling, clear both ORER and FER to 0. Receiving cannot resume if ORER or FER remain set to 1. When a framing error occurs, the RxD pin can be read to detect the break state.

Figure 15.16 shows an example of SCI receive operation using a multiprocessor format.

Figure 15.16 Example of SCI Receive Operation (8-Bit Data with Multiprocessor Bit and One Stop Bit)

Figure 15.16 Example of SCI Receive Operation (cont) (8-Bit Data with Multiprocessor Bit and One Stop Bit)

15.3.4 Synchronous Operation

In synchronous mode, the SCI transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCI transmitter and receiver are independent, so full-duplex communication is possible while sharing the same clock. The transmitter and receiver are also double buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 15.17 shows the general format in synchronous serial communication.

In synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data is guaranteed valid at the rising edge of the serial clock. In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB. In synchronous mode, the SCI transmits or receives data by synchronizing with the falling edge of the serial clock.

Communication Format: The data length is fixed at eight bits. No parity bit or multiprocessor bit can be added.

www.DataSheet4U.com

Clock: An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCI transmit/receive clock. The clock source is selected by the C/\overline{A} bit in the serial mode register (SCSMR) and bits CKE1 and CKE0 in the serial control register (SCSCR). See table 15.10.

When the SCI operates on an internal clock, it outputs the clock signal at the SCK pin. Eight clock pulses are output per transmitted or received character. When the SCI is not transmitting or receiving, the clock signal remains in the high state. When only receiving, the SCI receives in 2-character units, so a 16-pulse serial clock is output. To receive in 1-character units, select an external clock source.

Transmitting and Receiving Data SCI Initialization (Synchronous Mode): Before

transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCI. Clearing TE to 0 sets TDRE to 1 and initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags and receive data register (SCRDR), which retain their previous contents.

Figure 15.18 shows a sample flowchart for initializing the SCI. The procedure for initializing the SCI is:

- 1. Select the clock source in the serial control register (SCSCR). Leave RIE, TIE, TEIE, MPIE, TE and RE cleared to 0.
- 2. Select the communication format in the serial mode register (SCSMR).
- 3. Write the value corresponding to the bit rate in the bit rate register (SCBRR) (not necessary if an external clock is used).
- 4. Wait for at least the interval required to transmit or receive one bit, then set TE or RE in the serial control register (SCSCR) to 1. Also set RIE, TIE, TEIE and MPIE. Setting TE and RE allows use of the TxD and RxD pins.

Figure 15.18 Sample Flowchart for SCI Initialization

Transmitting Serial Data (Synchronous Mode): Figure 15.19 shows a sample flowchart for transmitting serial data. The procedure for transmitting serial data is:

- 1. SCI status check and transmit data write: Read the serial status register (SCSSR), check that the TDRE bit is 1, then write transmit data in the transmit data register (SCTDR) and clear TDRE to 0.
- 2. To continue transmitting serial data: Read the TDRE bit to check whether it is safe to write (if it reads 1); if so, write data in SCTDR, then clear TDRE to 0.

Figure 15.19 Sample Flowchart for Transmitting Serial Data

In transmitting serial data, the SCI operates as follows:

- 1. The SCI monitors the TDRE bit in SCSSR. When TDRE is cleared to 0 the SCI recognizes that the transmit data register (SCTDR) contains new data and loads this data from SCTDR into the transmit shift register (SCTSR).
- 2. After loading the data from SCTDR into SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in SCSCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time.

If clock output mode is selected, the SCI outputs eight synchronous clock pulses. If an external clock source is selected, the SCI outputs data in synchronization with the input clock. Data is output from the TxD pin in order from the LSB (bit 0) to the MSB (bit 7).

- 3. The SCI checks the TDRE bit when it outputs the MSB (bit 7). If TDRE is 0, the SCI loads data from SCTDR into SCTSR, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in SCSSR to 1, transmits the MSB, then holds the transmit data pin (TxD) in the MSB state. If the transmit-end interrupt enable bit (TEIE) in SCSCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.
- 4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 15.20 shows an example of SCI transmit operation.

Figure 15.20 Example of SCI Transmit Operation

Receiving Serial Data (Synchronous Mode): Figure 15.21 shows a sample flowchart for receiving serial data. When switching from asynchronous mode to synchronous mode, make sure that ORER, PER, and FER are cleared to 0. If PER or FER is set to 1, the RDRF bit will not be set and both transmitting and receiving will be disabled.

The procedure for receiving serial data is:

www.DataSheet4U.com

- 1. Receive error handling: If a receive error occurs, read the ORER bit in SCSSR to identify the error. After executing the necessary error handling, clear ORER to 0. Transmitting/receiving cannot resume if ORER remains set to 1.
- 2. SCI status check and receive data read: Read the serial status register (SCSSR), check that RDRF is set to 1, then read receive data from the receive data register (SCRDR) and clear RDRF to 0. The RXI interrupt can also be used to determine if the RDRF bit has changed from 0 to 1.
- 3. To continue receiving serial data: Read SCRDR, and clear RDRF to 0 before the MSB (bit 7) of the current frame is received.

Figure 15.21 Sample Flowchart for Receiving Serial Data

www.DataSheet4U.com

Figure 15.21 Sample Flowchart for Receiving Serial Data (cont)

In receiving, the SCI operates as follows:

- 1. The SCI synchronizes with serial clock input or output and initializes internally.
- 2. Receive data is shifted into SCRSR in order from the LSB to the MSB. After receiving the data, the SCI checks that RDRF is 0 so that receive data can be loaded from SCRSR into SCRDR. If this check is passed, the SCI sets RDRF to 1 and stores the received data in SCRDR. If the check is not passed (receive error), the SCI operates as indicated in table 15.12. This state prevents further transmission or reception. While receiving, the RDRF bit is not set to 1. Be sure to clear the error flag.
- 3. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in SCSCR, the SCI requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the receive-data-full interrupt enable bit (RIE) in SCSCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

Figure 15.22 shows an example of SCI receive operation.

www.DataSheet4U.com Rev. 5.0, 09/03, page 525 of 806

Figure 15.22 Example of SCI Receive Operation

Transmitting and Receiving Serial Data Simultaneously (Synchronous Mode): Figure 15.23 shows a sample flowchart for transmitting and receiving serial data simultaneously. The procedure for setting the SCI to transmit and receive serial data simultaneously is:

- 1. SCI status check and transmit data write: Read the serial status register (SCSSR), check that the TDRE bit is 1, then write transmit data in the transmit data register (SCTDR) and clear TDRE to 0. The TXI interrupt can also be used to determine if the TDRE bit has changed from 0 to 1.
- 2. Receive error handling: If a receive error occurs, read the ORER bit in SCSSR to identify the error. After executing the necessary error handling, clear ORER to 0. Transmitting/receiving cannot resume if ORER remains set to 1.
- 3. SCI status check and receive data read: Read the serial status register (SCSSR), check that RDRF is set to 1, then read receive data from the receive data register (SCRDR) and clear RDRF to 0. The RXI interrupt can also be used to determine if the RDRF bit has changed from 0 to 1.
- 4. To continue transmitting and receiving serial data: Read the RDRF bit and SCRDR, and clear RDRF to 0 before the MSB (bit 7) of the current frame is received. Also read the TDRE bit to check whether it is safe to write (if it reads 1); if so, write data in SCTDR, then clear TDRE to 0 before the MSB (bit 7) of the current frame is transmitted.

Figure 15.23 Sample Flowchart for Transmitting/Receiving Serial Data

15.4 SCI Interrupts

The SCI has four interrupt sources transmit-end (TEI), receive-error (ERI), receive-data-full (RXI), and transmit-data-empty (TXI). Table 15.13 lists the interrupt sources and indicates their priority. These interrupts can be enabled and disabled by the TIE, RIE, and TEIE bits in the serial control register (SCSCR). Each interrupt request is sent separately to the interrupt controller.

TXI is requested when the TDRE bit in SCSSR is set to 1. TDRE is automatically cleared to 0 when data is written in the transmit data register (SCTDR).

RXI is requested when the RDRF bit in SCSSR is set to 1. RDRF is automatically cleared to 0 when the receive data register (SCRDR) is read.

ERI is requested when the ORER, PER, or FER bit in SCSSR is set to 1.

TEI is requested when the TEND bit in SCSSR is set to 1. Where the TXI interrupt indicates that transmit data writing is enabled, the TEI interrupt indicates that the transmit operation is complete.

Table 15.13 SCI Interrupt Sources

| Interrupt Source | Description | Priority When Reset Is Cleared |
|------------------|-----------------------------------|--------------------------------|
| ERI | Receive error (ORER, PER, or FER) | High |
| RXI | Receive data full (RDRF) | ↑ |
| TXI | Transmit data empty (TDRE) | |
| TEI | Transmit end (TEND) | Low |

See section 4, Exception Handling, for priorities and the relationship to non-SCI interrupts.

15.5 Usage Notes

Note the following points when using the SCI.

SCTDR Writing and TDRE Flag: The TDRE bit in the serial status register (SCSSR) is a status flag indicating loading of transmit data from SCTDR into SCTSR. The SCI sets TDRE to 1 when it transfers data from SCTDR to SCTSR. Data can be written to SCTDR regardless of the TDRE bit state. If new data is written in SCTDR when TDRE is 0, however, the old data stored in SCTDR will be lost because the data has not yet been transferred to SCTSR. Before writing transmit data to SCTDR, be sure to check that TDRE is set to 1.

Simultaneous Multiple Receive Errors: Table 15.14 indicates the state of SCSSR status flags when multiple receive errors occur simultaneously. When an overrun error occurs, the SCRSR contents cannot be transferred to SCRDR, so receive data is lost.

| | SC | SSR Sta | tus Fla | Receive Data Transfer | |
|--|----|---------|---------|-----------------------|---------------------------|
| Receive Error Status | | ORER | FER | PER | $SCRSR \rightarrow SCRDR$ |
| Overrun error | 1 | 1 | 0 | 0 | Х |
| Framing error | 0 | 0 | 1 | 0 | 0 |
| Parity error | 0 | 0 | 0 | 1 | 0 |
| Overrun error + framing error | 1 | 1 | 1 | 0 | Х |
| Overrun error + parity error | 1 | 1 | 0 | 1 | Х |
| Framing error + parity error | 0 | 0 | 1 | 1 | 0 |
| Overrun error + framing error + parity error | 1 | 1 | 1 | 1 | Х |

Table 15.14 SCSSR Status Flags and Transfer of Receive Data

X: Receive data is not transferred from SCRSR to SCRDR.

O: Receive data is transferred from SCRSR to SCRDR.

Break Detection and Processing: Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state, the input from the RxD pin consists of all 0s, so FER is set and the parity error flag (PER) may also be set. In the break state, the SCI receiver continues to operate, so if the FER bit is cleared to 0, it will be set to 1 again.

Sending a Break Signal: The TxD pin I/O condition and level can be determined by means of the SCP0DT bit in the port SC data register (SCPDR) and bits SCP0MD0 and SCP0MD1 in the port SC control register (SCPCR). This feature can be used to send breaks. To send a break during serial transmission, clear the SCP0DT bit to 0 (designating low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD pin.

TEND Flag and TE Bit Processing: The TEND flag is set to 1 during transmission of the stop bit of the last data. Consequently, if the TE bit is cleared to 0 immediately after setting of the TEND flag has been confirmed, the stop bit will be in the process of transmission and will not be transmitted normally. Therefore, the TE bit should not be cleared to 0 for at least 0.5 serial clock cycles (or 1.5 cycles if two stop bits are used) after setting of the TEND flag is confirmed.

Receive Error Flags and Transmitter Operation (Synchronous Mode Only): When a receive error flag (ORER, PER, or FER) is set to 1, the SCI will not start transmitting even if TDRE is set to 1. Be sure to clear the receive error flags to 0 before starting to transmit. Note that clearing RE to 0 does not clear the receive error flags.

Receive Data Sampling Timing and Receive Margin in Asynchronous Mode: In asynchronous mode, the SCI operates on a base clock of 16 times the transfer rate frequency. In receiving, the SCI synchronizes internally with the falling edge of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse (figure 15.24).

Figure 15.24 Receive Data Sampling Timing in Asynchronous Mode

The receive margin in asynchronous mode can therefore be expressed as in equation 1. Equation 1:

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where: M = Receive margin (%) N = Ratio of clock frequency to bit rate (N = 16) D = Clock duty cycle (D = 0 to 1.0) L = Frame length (L = 9 to 12)F = Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as in equation 2.

Equation 2:

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

Notes on Synchronous External Clock Mode:

- Set TE = RE = 1 only when external clock SCK is 1.
- Do not set TE = RE = 1 until at least four clocks after external clock SCK has changed from 0 to 1.
- When receiving, RDRF is set to 1 when RE is set to zero 2.5–3.5 clocks after the rising edge of the SCK input of the D7 bit in RxD, but data cannot be copied to SCRDR.

Note on Synchronous Internal Clock Mode: When receiving, RDRF is set to 1 when RE is cleared to zero 1.5 clocks after the rising edge of the SCK output of the D7 bit in RxD, but data cannot be copied to SCRDR.

Section 16 Smart Card Interface

16.1 Overview

As an added serial communications interface function, the SCI supports an IC card (smart card) interface that conforms to the ISO/IEC7816-3 (Identification Card) data transmission protocol format T = 0 (asynchronous full-duplex character transmission protocol). Register settings are used to switch between the normal serial communication interface and the smart card interface.

16.1.1 Features

The smart card interface has the following features:

- Asynchronous mode
 - Data length: 8 bits
 - Parity bit generation and check
 - Receive mode error signal detection (parity error)
 - Transmit mode error signal detection and automatic re-transmission of data
 - Supports both direct convention and inverse convention
- Bit rate can be selected using on-chip baud rate generator.
- Three types of interrupts: Transmit-data-empty, receive-data-full, and communication-error interrupts are requested independently.

16.1.2 Block Diagram

Figure 16.1 Block Diagram of Smart Card Interface

16.1.3 Pin Configuration

Table 16.1 summarizes the smart card interface pins.

| Pin Name | Abbreviation | I/O | Function |
|-------------------|--------------|--------|----------------------|
| Serial clock pin | SCK0 | Output | Clock output |
| Receive data pin | RxD0 | Input | Receive data input |
| Transmit data pin | TxD0 | Output | Transmit data output |

Table 16.1 Smart Card Interface Pins

16.1.4 Smart Card Interface Registers

Table 16.2 summarizes the registers used by the smart card interface. The SCSMR, SCBRR, SCSCR, SCTDR, and SCRDR registers are the same as for the normal SCI function. They are described in section 15, Serial Communication Interface (SCI).

| Name | Abbreviation | R/W | Initial Value ^{*3} | Address | Access Size |
|--------------------------|--------------|---------|-----------------------------|------------|-------------|
| Serial mode register | SCSMR | R/W | H'00 | H'FFFFFE80 | 8 |
| Bit rate register | SCBRR | R/W | H'FF | H'FFFFFE82 | 8 |
| Serial control register | SCSCR | R/W | H'00 | H'FFFFFE84 | 8 |
| Transmit data register | SCTDR | R/W | H'FF | H'FFFFFE86 | 8 |
| Serial status register | SCSSR | R/(W)*1 | H'84 | H'FFFFFE88 | 8 |
| Receive data register | SCRDR | R | H'00 | H'FFFFFE8A | 8 |
| Smart card mode register | SCSCMR | R/W | H'00 ^{*2} | H'FFFFFE8C | 8 |

Table 16.2 Registers

Notes: 1. Only 0 can be written, to clear the flags.

2. Bits 0, 2, and 3 are cleared. The value of the other bits is undefined.

3. Initialized by a power-on or manual reset.

16.2 Register Descriptions

This section describes the registers added for the smart card interface and the bits whose functions are changed.

16.2.1 Smart Card Mode Register (SCSCMR)

The smart card mode register (SCSCMR) is an 8-bit readable/writable register that selects smart card interface functions. SCSCMR bits 0, 2, and 3 are initialized to H'00 by a reset and in standby mode.

| Bit: | 7 | 6 | 5 | 4 | 4 3 | | 1 | 0 |
|----------------|---|---|---|---|------|------|---|------|
| | | | _ | _ | SDIR | SINV | _ | SMIF |
| Initial value: | | — | — | | 0 | 0 | _ | 0 |
| R/W: | R | R | R | R | R/W | R/W | R | R/W |

Bits 7 to 4 and 1—Reserved: These bits are always read as 0. The write value should always be 0.

Bit 3—Smart Card Data Transfer Direction (SDIR): Selects the serial/parallel conversion format.

| Bit 3: SDIR | Description |
|-------------|--|
| 0 | Contents of SCTDR are transferred LSB-first, and receive data is stored in SCRDR LSB-first (Initial value) |
| 1 | Contents of SCTDR are transferred MSB-first, and receive data is stored in SCRDR MSB-first |

Bit 2—Smart Card Data Inversion (SINV): Specifies whether to invert the logic level of the data. This function is used in combination with bit 3 for transmitting and receiving with an inverse convention card. SINV does not affect the logic level of the parity bit. See section 16.3.4, Register Settings, for information on how parity is set.

| Bit 2: SINV | Description |
|-------------|---|
| 0 | Contents of SCTDR are transferred unchanged, and receive data is stored in SCRDR unchanged (Initial value) |
| 1 | Contents of SCTDR are inverted before transfer, and receive data is inverted before storage in SCRDR |

| Bit 0 : SMIF | Description | |
|--------------|--|-----------------|
| 0 | Smart card interface function disabled | (Initial value) |
| 1 | Smart card interface function enabled | |

www.DataSheet4U.com

16.2.2 Serial Status Register (SCSSR)

In smart card interface mode, the function of SCSSR bit 4 is changed. The setting conditions for bit 2, the TEND bit, are also changed.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|--------|--------|--------|---------|--------|------|-----|------|
| | TDRE | RDRF | ORER | FER/ERS | PER | TEND | MPB | MPBT |
| Initial value: | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| R/W: | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R | R | R/W |

Note: * Only 0 can be written, to clear the flag.

Bits 7 to 5: These bits have the same function as in the ordinary SCI. See section 15, Serial Communication Interface (SCI), for more information.

Bit 4—Error Signal Status (ERS): In the smart card interface mode, bit 4 indicates the state of the error signal returned from the receiving side during transmission. The smart card interface cannot detect framing errors.

| Bit 4: ERS | Description | | | | | |
|------------|--|---|--|--|--|--|
| 0 | Receiving ended normally with no error signal (In | | | | | |
| | ERS is cleared to 0 when the chip is reset or enters standby mode, software reads ERS after it has been set to 1, then writes 0 to ERS | , | | | | |
| 1 | An error signal indicating a parity error was transmitted from the receiving side | | | | | |
| | ERS is set to 1 if the error signal sampled is low. | | | | | |

Note: The ERS flag maintains its state even when the TE bit in SCSCR is cleared to 0.

Bits 3 to 0: These bits have the same function as in the ordinary SCI. See section 15, Serial Communication Interface (SCI), for more information. The setting conditions for bit 2, the transmit end bit (TEND), are changed as follows.

| Bit 2: TEND | Description | | | | | | | |
|-------------|--|-----------------------------|--|--|--|--|--|--|
| 0 | Transmission is in progress | Transmission is in progress | | | | | | |
| | TEND is cleared to 0 when software reads TDRE after it has bee writes 0 to TDRE. | en set to 1, then | | | | | | |
| 1 | End of transmission | (Initial value) | | | | | | |
| | TEND is set to 1 when: | | | | | | | |
| | the chip is reset or enters standby mode, | | | | | | | |
| | the TE bit in SCSCR is 0 and the FER/ERS bit is also 0, | | | | | | | |
| | the C/ \overline{A} bit in SCSMR is 0, and TDRE = 1 and FER/ERS = 0 (not transmission) 2.5 etu after a one-byte serial character is transmit | | | | | | | |
| | the C/ \overline{A} bit in SCSMR is 1, and TDRE = 1 and FER/ERS = 0 (not transmission) 1.0 etu after a one-byte serial character is transmit | | | | | | | |

Note: etu: Elementary Time Unit (time for transfer of 1 bit)

16.3 Operation

16.3.1 Overview

The primary functions of the smart card interface are described below.

- 1. Each frame consists of 8-bit data and 1 parity bit.
- 2. During transmission, the card leaves a guard time of at least 2 etu (elementary time units: time for transfer of 1 bit) from the end of the parity bit to the start of the next frame.
- 3. During reception, the card outputs an error signal low level for 1 etu after 10.5 etu has elapsed from the start bit if a parity error was detected.
- 4. During transmission, it automatically transmits the same data after allowing at least 2 etu from the time the error signal is sampled.
- 5. Only start-stop type asynchronous communication functions are supported; no synchronous communication functions are available.

16.3.2 Pin Connections

Figure 16.2 shows the pin connection diagram for the smart card interface. During communication with an IC card, transmission and reception are both carried out over the same data transfer line, so connect the TxD and RxD pins on the chip. Pull up the data transfer line to the power supply V_{CC} side with a resistor.

www.DataSheet4U.com

When using the clock generated by the smart card interface on an IC card, input the SCK pin output to the IC card's CLK pin. This connection is not necessary when the internal clock is used on the IC card.

Use the chip's port output as the reset signal. Apart from these pins, power and ground pin connections are usually also required.

Note: When the IC card is not connected and both RE and TE are set to 1, closed communication is possible and auto-diagnosis can be performed.

Figure 16.2 Pin Connection Diagram for Smart Card Interface

16.3.3 Data Format

Figure 16.3 shows the data format for the smart card interface. In this mode, parity is checked every frame while receiving and error signals sent to the transmitting side whenever an error is detected so that data can be re-transmitted. During transmission, error signals are sampled and data re-transmitted whenever an error signal is detected.

Figure 16.3 Data Format for Smart Card Interface

The operating sequence is:

- 1. The data line is high-impedance when not in use and is fixed high with a pull-up resistor.
- 2. The transmitting side starts one frame of data transmission. The data frame starts with a start bit (Ds, low level). The start bit is followed by eight data bits (D0–D7) and a parity bit (Dp).
- 3. On the smart card interface, the data line returns to high-impedance after this. The data line is pulled high with a pull-up resistor.
- 4. The receiving side checks parity. When the data is received normally with no parity errors, the receiving side then waits to receive the next data. When a parity error occurs, the receiving side outputs an error signal (DE, low level) and requests re-transfer of data. The receiving station returns the signal line to high-impedance after outputting the error signal for a specified period. The signal line is pulled high with a pull-up resistor.

www.DataSheet4U.com

Rev. 5.0, 09/03, page 540 of 806

5. The transmitting side transmits the next frame of data unless it receives an error signal. If it does receive an error signal, it returns to step 2 to re-transmit the erroneous data.

16.3.4 Register Settings

Table 16.3 shows the bit map of the registers that the smart card interface uses. Bits shown as 1 or 0 must be set to the indicated value. The settings for the other bits are described below.

| Register | Address | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|----------|------------|-------|-------|-------|-------------|-------|-------|-------|-------|
| SCSMR | H'FFFFFE80 | C/Ā | 0 | 1 | O/E | 1 | 0 | CKS1 | CKS0 |
| SCBRR | H'FFFFFE82 | BRR7 | BRR6 | BRR5 | BRR4 | BRR3 | BRR2 | BRR1 | BRR0 |
| SCSCR | H'FFFFFE84 | TIE | RIE | TE | RE | 0 | 0 | CKE1 | CKE0 |
| SCTDR | H'FFFFFE86 | TDR7 | TDR6 | TDR5 | TDR4 | TDR3 | TDR2 | TDR1 | TDR0 |
| SCSSR | H'FFFFFE88 | TDRE | RDRF | ORER | FER/ ERS | PER | TEND | 0 | 0 |
| SCRDR | H'FFFFFE8A | RDR7 | RDR6 | RDR5 | RDR4 | RDR3 | RDR2 | RDR1 | RDR0 |
| SCSCMR | H'FFFFFE8C | — | — | — | — | SDIR | SINV | | SMIF |

 Table 16.3
 Register Settings for Smart Card Interface

Note: Dashes indicate unused bits.

- Setting the serial mode register (SCSMR): The C/A bit selects the setting timing of the TEND flag, and selects the clock output state in combination with bits CKE1 and CKE0 in the serial control register (SCSCR). Clear the O/E bit to 0 if the IC card uses the direct convention, and set it to 1 if the card uses the inverse convention. Select the on-chip baud rate generator clock source with the CKS1 and CKS0 bits (see section 16.3.5, Clock).
- 2. Setting the bit rate register (SCBRR): Set the bit rate. See section 16.3.5, Clock, to see how to calculate the set value.
- 3. Setting the serial control register (SCSCR): The TIE, RIE, TE and RE bits function as they do for the ordinary SCI. See section 15, Serial Communication Interface (SCI), for more information. The CKE0 bit specifies the clock output. When no clock is output, clear CKE0 to 0; when a clock is output, set CKE0 to 1.
- 4. Setting the smart card mode register (SCSCMR): The SDIR and SINV bits are both cleared to 0 for IC cards that use the direct convention, and both set to 1 when the inverse convention is used. The SMIF bit is set to 1 for the smart card interface.

Figure 16.4 shows sample waveforms for register settings of the two types of IC cards (direct convention and inverse convention) and their start characters.

In the direct convention type, the logical 1 level is state Z, the logical 0 level is state A, and communication is LSB-first. The start character data is H'3B. Parity is even (from the smart card standard), and so the parity bit is 1.

In the inverse convention type, the logical 1 level is state A, the logical 0 level is state Z, and communication is MSB first. The start character data is H'3F. Parity is even (from the smart card standard), and so the parity bit is 0, which corresponds to state Z.

Only data bits D7–D0 are inverted by the SINV bit. To invert the parity bit, set the O/\overline{E} bit in SCSMR to odd parity mode. This applies to both transmission and reception.

Figure 16.4 Waveform of Start Character

16.3.5 Clock

Only the internal clock generated by the on-chip baud rate generator can be used as the communication clock in the smart card interface. The bit rate for the clock is set by the bit rate register (SCBRR) and the CKS1 and CKS0 bits in the serial mode register (SCSMR), and is calculated using the equation below. Table 16.5 shows sample bit rates. If clock output is then selected by setting CKE0 to 1, a clock with a frequency 372 times the bit rate is output from the SCK0 pin.

$$\mathsf{B} = \frac{\mathsf{P} \phi}{1488 \times 2^{2n-1} \times (\mathsf{N}+1)} \times 10^6$$

Where: N = Value set in SCBRR ($0 \le N \le 255$) B = Bit rate (bits/s) P ϕ = Peripheral module operating frequency (MHz) n = 0 to 3 (table 16.4)

www.DataSheet4U.com

| n | CKS1 | CKS0 |
|---------------------------|------|------|
| 0 | 0 | 0 |
| 1 | 0 | 1 |
| 2 www.DataShoot/II.com | 1 | 0 |
| 3 | 1 | 1 |

Table 16.4 Relationship of n to CKS1 and CKS0

Table 16.5 Examples of Bit Rate B (Bits/s) for SCBRR Settings (n = 0)

| | | Ρφ (MHz) | | | | | | | |
|---|--------|----------|---------|---------|---------|---------|---------|--|--|
| Ν | 7.1424 | 10.00 | 10.7136 | 13.00 | 14.2848 | 16.00 | 18.00 | | |
| 0 | 9600.0 | 13440.9 | 14400.0 | 17473.1 | 19200.0 | 21505.4 | 24193.5 | | |
| 1 | 4800.0 | 6720.4 | 7200.0 | 8736.6 | 9600.0 | 10752.7 | 12096.8 | | |
| 2 | 3200.0 | 4480.3 | 4800.0 | 5824.4 | 6400.0 | 7168.5 | 8064.5 | | |

Note: The bit rate is rounded to one decimal place.

Calculate the value to be set in the bit rate register (SCBRR) from the operating frequency and the bit rate. N is an integer in the range $0 \le N \le 255$, specifying a smallish error.

$$N = \frac{P\varphi}{1488 \times 2^{2n-1} \times B} \times 10^6 - 1$$

 Table 16.6
 Examples of SCBRR Settings for Bit Rate B (Bits/s) (n = 0)

| 7 | 7.1424 | | 10.00 | 1 | 0.7136 | - | 13.00 | - | 4.2848 | | 16.00 | | 18.00 |

 Table 16.7
 Maximum Bit Rates for Frequencies (Smart Card Interface Mode)

The bit rate error is found as follows:

Error (%) =
$$(\frac{P\phi}{1488 \times 2^{2n-1} \times B \times (N+1)} \times 10^{6} - 1) \times 100$$

Table 16.8 shows the relationship between transmit/receive clock register set values and output states on the smart card interface.

| | | Regi | ster Value | • | SCK Pin | | | |
|-----------------|------|------|------------|------|-------------|---|--|--|
| Setting | SMIF | C/Ā | CKE1 | CKE0 | Output | State | | |
| 1 ^{*1} | 1 | 0 | 0 | 0 | Port | Determined by setting of port register SCP1MD1 and SCP1MD0 bits | | |
| | 1 | 0 | 0 | 1 | wn | SCK (serial clock) output state | | |
| 2 ^{*2} | 1 | 1 | 0 | 0 | Low output | Low output state | | |
| | 1 | 1 | 0 | 1 | UUL. | SCK (serial clock) output state | | |
| 3 ^{*2} | 1 | 1 | 1 | 0 | High output | High output state | | |
| | 1 | 1 | 1 | 1 | un. | SCK (serial clock) output state | | |

Table 16.8 Register Set Values and SCK Pin

Notes: 1. The SCK output state changes as soon as the CKE0 bit is modified. The CKE1 bit should be cleared to 0.

2. The clock duty remains constant despite stopping and starting of the clock by modification of the CKE0 bit.

16.3.6 Data Transmission and Reception

Initialization: Initialize the SCI using the following procedure before sending or receiving data. Initialization is also required for switching from transmit mode to receive mode or from receive mode to transmit mode. Figure 16.5 shows a flowchart of the initialization process.

- 1. Clear TE and RE in the serial control register (SCSCR) to 0.
- 2. Clear error flags FER/ERS, PER, and ORER to 0 in the serial status register (SCSSR).
- 3. Set the C/\overline{A} bit, parity bit (O/\overline{E} bit), and baud rate generator select bits (CKS1 and CKS0 bits) in the serial mode register (SCSMR). At this time also clear the CHR and MP bits to 0 and set the STOP and PE bits to 1.
- 4. Set the SMIF, SDIR, and SINV bits in the smart card mode register (SCSCMR). When the SMIF bit is set to 1, the TxD and RxD pins both switch from ports to SCI pins and become high-impedance.
- 5. Set the value corresponding to the bit rate in the bit rate register (SCBRR).
- 6. Set the clock source select bits (CKE1 and CKE0 bits) in the serial control register (SCSCR). Clear the TIE, RIE, TE, RE, MPIE, and TEIE bits to 0. When the CKE0 bit is set to 1, a clock is output from the SCK pin.
- 7. After waiting at least 1 bit, set the TIE, RIE, TE, and RE bits in SCSCR. Do not set the TE and RE bits simultaneously unless performing auto-diagnosis.

Figure 16.5 Initialization Flowchart (Example)

Serial Data Transmission: The processing procedures in the smart card mode differ from ordinary SCI processing because data is retransmitted when an error signal is sampled during a data transmission. This results in the transmission processing flowchart shown in figure 16.6.

- 1. Initialize the smart card interface mode as described in Initialization above.
- 2. Check that the FER/ERS bit in SCSSR is cleared to 0.
- 3. Repeat steps 2 and 3 until the TEND flag in SCSSR is set to 1.
- 4. Write the transmit data into SCTDR, clear the TDRE flag to 0 and start transmitting. The TEND flag will be cleared to 0.
- 5. To transmit more data, return to step 2.
- 6. To end transmission, clear the TE bit to 0.

This processing can be interrupted. When the TIE bit is set to 1 and interrupt requests are enabled, a transmit-data-empty interrupt (TXI) will be requested when the TEND flag is set to 1 at the end of transmission. When the RIE bit is set to 1 and interrupt requests are enabled, a communication error interrupt (ERI) will be requested when the ERS flag is set to 1 when an error occurs in transmission. See Interrupt Operation below for more information.

Figure 16.6 Transmission Flowchart

Serial Data Reception: The processing procedures in smart card mode are the same as in ordinary SCI processing. The reception processing flowchart is shown in figure 16.7.

- 1. Initialize the smart card interface mode as described above in Initialization and in figure 16.5.
- 2. Check that the ORER and PER flags in SCSSR are cleared to 0. If either flag is set, clear both to 0 after performing the appropriate error handling procedures.
- 3. Repeat steps 2 and 3 until the RDRF flag is set to 1.
- 4. Read the receive data from SCRDR.
- 5. To receive more data, clear the RDRF flag to 0 and return to step 2.
- 6. To end reception, clear the RE bit to 0.

This processing can be interrupted. When the RIE bit is set to 1 and interrupt requests are enabled, a receive-data-full interrupt (RXI) will be requested when the RDRF flag is set to 1 at the end of reception. When an error occurs during reception and either the ORER or PER flag is set to 1, a communication error interrupt (ERI) will be requested. See Interrupt Operation below for more information.

The received data will be transferred to SCRDR even when a parity error occurs during reception and PER is set to 1, so this data can still be read.

Figure 16.7 Reception Flowchart (Example)

Switching Modes: When switching from receive mode to transmit mode, check that the receive operation is completed before starting initialization, clearing RE to 0, and setting TE to 1. The RDRF, PER, and ORER flags can be used to check if reception is completed. When switching from transmit mode to receive mode, check that the transmit operation is completed before starting initialization, clearing TE to 0, and setting RE to 1. The TEND flag can be used to check if transmission is completed.

www.DataSheet4U.com

Interrupt Operation: In the smart card interface mode, there are three types of interrupts: transmit-data-empty (TXI), communication error (ERI) and receive-data-full (RXI). In this mode, the transmit-end interrupt (TEI) cannot be requested.

Set the TEND flag in SCSSR to 1 to request a TXI interrupt. Set the RDRF flag in SCSSR to 1 to request an RXI interrupt. Set the ORER, PER, or FER/ERS flag in SCSSR to 1 to request an ERI interrupt (table 16.9).

| Mode | State | Flag | Mask Bit | Interrupt Source |
|---------------|--------|--------------|----------|------------------|
| Transmit mode | Normal | TEND | TIE | TXI |
| | Error | FER/ERS | RIE | ERI |
| Receive mode | Normal | RDRF | RIE | RXI |
| | Error | PER, ORER | RIE | ERI |

Table 16.9 Smart Card Mode Operating State and Interrupt Sources

16.4 Usage Notes

When the SCI is used as a smart card interface, be sure that all criteria in sections 16.4.1, Receive Data Timing and Receive Margin in Asynchronous Mode and 16.4.2, Retransmission (Receive and Transmit Modes) are applied.

16.4.1 Receive Data Timing and Receive Margin in Asynchronous Mode

In asynchronous mode, the SCI runs on a base clock with a frequency of 372 times the transfer rate. During reception, the SCI samples the falling of the start bit using the base clock to achieve internal synchronization. Receive data is latched internally at the rising edge of the 186th base clock cycle (figure 16.8).

www.DataSheet4U.com Rev. 5.0, 09/03, page 551 of 806

The receive margin is found from the following equation:

For smart card mode:

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where: M = Receive margin (%) N = Ratio of bit rate to clock (N = 372) D = Clock duty (D = 0 to 1.0) L = Frame length (L = 10)F = Absolute value of clock frequency deviation

Using this equation, the receive margin when F = 0 and D = 0.5 is as follows:

 $M = (0.5 - 1/2 \times 372) \times 100\% = 49.866\%$

www.DataSheet4U.com

16.4.2 Retransmission (Receive and Transmit Modes)

Retransmission when SCI is in Receive Mode: Figure 16.9 shows the retransmission operation in the SCI receive mode.

- 1. When the received parity bit is checked and an error is found, the PER bit in SCSSR is automatically set to 1. If the RIE bit in SCSCR is enabled at this time, an ERI interrupt is requested. Be sure to clear the PER bit before the next parity bit is sampled.
- 2. The RDRF bit in SCSSR is not set in the frame that caused the error.
- 3. When the received parity bit is checked and no error is found, the PER bit in SCSSR is not set.
- 4. When the received parity bit is checked and no error is found, reception is considered to have been completed normally and the RDRF bit in SCSSR is automatically set to 1. If the RIE bit in SCSCR is enabled at this time, an RXI interrupt is requested.
- 5. When a normal frame is received, the pin maintains a three-state state when it transmits the error signal.

Figure 16.9 Retransmission in SCI Receive Mode

Retransmission when SCI is in Transmit Mode: Figure 16.10 shows the retransmission operation in the SCI transmit mode.

- 1. After transmission of one frame is completed, the FER/ERS bit in SCSSR is set to 1 when a error signal is returned from the receiving side. If the RIE bit in SCSCR is enabled at this time, an ERI interrupt is requested. Be sure to clear the FER/ERS bit before the next parity bit is sampled.DataSheet4U.com
- 2. The TEND bit in SCSSR is not set in the frame that received the error signal indicating the error.
- 3. The FER/ERS bit in SCSSR is not set when no error signal is returned from the receiving side.
- 4. When no error signal is returned from the receiving side, the TEND bit in SCSSR is set to 1 when the transmission of the frame that includes the retransmission is considered completed. If the TIE bit in SCSCR is enabled at this time, a TXI interrupt will be requested.

Figure 16.10 Retransmission in SCI Transmit Mode

Section 17 Serial Communication Interface with FIFO (SCIF)

17.1 Overview

www.DataSheet4U.com

The SH7729R has a two-channel serial communication interface with FIFO (SCIF) that supports asynchronous serial communication. It also has 16-stage FIFO registers for both transmission and reception that enable the SH7729R to perform efficient high-speed continuous communication.

17.1.1 Features

- Asynchronous serial communication:
 - Serial data communication is performed by start-stop in character units. The SCI can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are eight selectable serial data communication formats.
 - Data length: 7 or 8 bits
 - Stop bit length: 1 or 2 bits
 - Parity: Even, odd, or none
 - Receive error detection: Parity and framing errors
 - Break detection: Break is detected when a framing error is followed by at least one frame at the space 0 level (low level). It is also detected by reading the RxD level directly from the port SC data register (SCPDR) when a framing error occurs.
- Full duplex communication: The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use 16-stage FIFO buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK pin (external)
- Four types of interrupts: Transmit-FIFO-data-empty, break, receive-FIFO-data-full, and receive-error interrupts are requested independently. The direct memory access controller (DMAC) can be activated to execute a data transfer by a transmit-FIFO-data-empty or receive-FIFO-data-full interrupt.
- When the SCIF is not in use, it can be stopped by halting the clock supplied to it, saving power.
- On-chip modem control functions (RTS and CTS)
- The quantity of data in the transmit and receive FIFO registers and the number of receive errors of the receive data in the receive FIFO register can be ascertained.
- A time-out error (DR) can be detected when receiving.

www.DataSheet4U.com Rev. 5.0, 09/03, page 555 of 806

17.1.2 Block Diagram

Figure 17.1 shows a block diagram of the SCIF.

Figure 17.1 Block Diagram of SCIF

Figures 17.2 to 17.4 show the SCIF I/O port pins.

SCIF pin I/O and data control is performed by bits 11 to 8 of SCPCR and bits 5 and 4 of SCPDR. For details, see section 15.2.8, SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR).

www.DataSheet4U.com Rev. 5.0, 09/03, page 557 of 806

Figure 17.3 SCPT[4]/TxD2 Pin

Figure 17.4 SCPT[4]/RxD2 Pin

17.1.3 Pin Configuration

The SCIF has the serial pins summarized in table 17.1.

Table 17.1 SCIF Pins

| Pin Name | Abbreviation | I/O | Function |
|---------------------|--------------|--------|----------------------|
| Serial clock pin | SCK2 | I/O | Clock I/O |
| Receive data pin | RxD2 | Input | Receive data input |
| Transmit data pin | TxD2 | Output | Transmit data output |
| Request to send pin | RTS2 | Output | Request to send |
| Clear to send pin | CTS2 | Input | Clear to send |

17.1.4 Register Configuration

Table 17.2 summarizes the SCIF internal registers. These registers specify the data format and bit rate, and control the transmitter and receiver sections.

Table 17.2 SCIF Registers

ww.DataSheet4U.com

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|-------------------------------|--------------|---------|---------------|--|----------------|
| Serial mode register 2 | SCSMR2 | R/W | H'00 | H'04000150 (H'A4000150) ^{*2} | 8 bits |
| Bit rate register 2 | SCBRR2 | R/W | H'FF | H'04000152 (H'A4000152) ^{*2} | 8 bits |
| Serial control register 2 | SCSCR2 | R/W | H'00 | H'04000154 (H'A4000154) ^{*2} | 8 bits |
| Transmit FIFO data register 2 | SCFTDR2 | W | _ | H'04000156 (H'A4000156) ^{*2} | 8 bits |
| Serial status register 2 | SCSSR2 | R/(W)*1 | H'0060 | H'04000158 (H'A4000158) ^{*2} | 16 bits |
| Receive FIFO data register 2 | SCFRDR2 | R | Undefined | H'0400015A (H'A400015A) ^{*2} | 8 bits |
| FIFO control register 2 | SCFCR2 | R/W | H'00 | H'0400015C (H'A400015C) ^{*2} | 8 bits |
| FIFO data count register 2 | SCFDR2 | R | H'0000 | H'0400015E (H'A400015E) ^{*2} | 16 bits |

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

- 1. Only 0 can be written to clear the flag.
- 2. When address translation by the MMU does not apply, the address in parentheses should be used.

17.2 Register Descriptions

17.2.1 Receive Shift Register (SCRSR)

The receive shift register (SCRSR) receives serial data. Data input at the RxD pin is loaded into SCRSR in the order received; LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to SCFRDR, the receive FIFO data register. The CPU cannot read or write to SCRSR directly.

17.2.2 Receive FIFO Data Register (SCFRDR)

The 16-byte receive FIFO data register (SCFRDR) stores serial receive data. The SCIF completes the reception of one byte of serial data by moving the received data from the receive shift register (SCRSR) into SCFRDR for storage. Continuous reception is possible until 16 bytes are stored.

The CPU can read but not write to SCFRDR. If data is read when there is no receive data in the SCFRDR, the value is undefined. When this register is full of receive data, subsequent serial data is lost.

17.2.3 Transmit Shift Register (SCTSR)

The transmit shift register (SCTSR) transmits serial data. The SCI loads transmit data from the transmit FIFO data register (SCFTDR) into SCTSR, then transmits the data serially from the TxD pin, LSB (bit 0) first. After transmitting one data byte, the SCI automatically loads the next transmit data from SCFTDR into SCTSR and starts transmitting again. The CPU cannot read or write to SCTSR directly.

www.DataSheet4U.com Rev. 5.0, 09/03, page 561 of 806

17.2.4 Transmit FIFO Data Register (SCFTDR)

The transmit FIFO data register (SCFTDR) is a FIFO register comprising sixteen 8-bit stages that stores data for serial transmission. When the SCIF detects that the transmit shift register (SCTSR) is empty, it moves transmit data written in the SCFTDR into SCTSR and starts serial transmission. Continuous serial transmission is performed until there is no transmit data left in SCFTDR. The CPU can always write to SCFTDR.

When SCFTDR is full of transmit data (16 stages), no more data can be written. If writing of new data is attempted, the data is ignored.

17.2.5 Serial Mode Register (SCSMR)

The serial mode register (SCSMR) is an 8-bit register that specifies the SCIF serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to SCSMR. SCSMR is initialized to H'00 by a reset and in standby or module standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|-----|-----|-----|------|---|------|------|
| | _ | CHR | PE | O/Ē | STOP | _ | CKS1 | CKS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/W | R/W | R/W | R/W | R | R/W | R/W |

Bit 7—Reserved: This bit is always read as 0. The write value should always be 0.

| Bit 6—Character Length (CHR): Selects 7 | 7-bit or 8-bit data in asynchronous mode. |
|---|---|
|---|---|

| Bit 6: CHR | Description | |
|------------|--|------------------|
| 0 | 8-bit data | (Initial value) |
| 1 | 7-bit data | |
| | When 7-bit data is selected, the MSB (bit 7) of the transmit FIFO not transmitted. | data register is |

www.DataSheet4U.com

Bit 5—Parity Enable (PE): Selects whether to add a parity bit to transmit data and to check the parity of receive data.

| Bit 5: PE | Description | |
|-------------|--|-----------------|
| 0 | Parity bit not added or checked | (Initial value) |
| 1 www.Da | Parity bit added and checked taSheet40.com When PE is set to 1, an even or odd parity bit is added to trar depending on the parity mode (O/\overline{E}) setting. Receive data pa according to the even/odd (O/\overline{E}) mode setting. | |

Bit 4—Parity Mode (O/E): Selects even or odd parity when parity bits are added and checked. The O/\overline{E} setting is used only when the parity enable bit (PE) is set to 1 to enable parity addition and checking. The O/\overline{E} setting is ignored when parity addition and checking is disabled.

| Bit 4: O/E | Description | | | | |
|------------|---|----------------------|--|--|--|
| 0 | Even parity | (Initial value) | | | |
| | If even parity is selected, the parity bit is added to transmit data to make an ever number of 1s in the transmitted character and parity bit combined. Receive data is checked to see if it has an even number of 1s in the received character and parity bit combined. | | | | |
| 1 | Odd parity | | | | |
| | If odd parity is selected, the parity bit is added to transmit number of 1s in the transmitted character and parity bit co is checked to see if it has an odd number of 1s in the rece parity bit combined. | mbined. Receive data | | | |

Bit 3—Stop Bit Length (STOP): Selects one or two bits as the stop bit length.

When receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit, but if the second stop bit is 0, it is treated as the start bit of the next incoming character.

| Bit 3: STOP | Description | | | | |
|-------------|--|-----------------|--|--|--|
| 0 | One stop bit | (Initial value) | | | |
| | When transmitting, a single 1-bit is added at the end of each transmitted character. | | | | |
| 1 | Two stop bits | | | | |
| | When transmitting, two 1-bits are added at the end of each transmi | tted character. | | | |

Bit 2—Reserved: This bit is always read as 0. The write value should always be 0.

Bits 1 and 0—**Clock Select 1 and 0 (CKS1, CKS0):** Select the internal clock source of the onchip baud rate generator. Four clock sources are available. P ϕ , P ϕ /4, P ϕ /16 and P ϕ /64. For further information on the clock source, bit rate register settings, and baud rate, see section 17.2.8, Bit Rate Register (SCBRR).

| Bit 1: CKS1 | Bit 0: CKS0 | Description | |
|-------------|----------------|-------------|-----------------|
| 0 www.Dat | itaSheet4U.com | Рф | (Initial value) |
| | 1 | Ρφ/4 | |
| 1 | 0 | Ρφ/16 | |
| | 1 | Ρφ/64 | |

Note: Po: Peripheral clock

17.2.6 Serial Control Register (SCSCR)

The serial control register (SCSCR) operates the SCIF transmitter/receiver, selects the serial clock output in asynchronous mode, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write to SCSCR. SCSCR is initialized to H'00 by a reset and in standby or module standby mode.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|-----|-----|---|---|------|------|
| | TIE | RIE | TE | RE | — | _ | CKE1 | CKE0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R | R | R/W | R/W |

Bit 7—Transmit Interrupt Enable (TIE): Enables or disables the transmit-FIFO-data-empty interrupt (TXI) requested when the serial transmit data is transferred from the transmit FIFO data register (SCFTDR) to the transmit shift register (SCTSR), when the quantity of data in the transmit FIFO register becomes less than the specified number of transmission triggers, and when the TDFE flag in the serial FIFO status register (SCFSR) is set to1.

| Bit 7: TIE | Description |
|------------|---|
| 0 | Transmit-FIFO-data-empty interrupt request (TXI) is disabled (Initial value) |
| | The TXI interrupt request can be cleared by writing a greater quantity of transmit data than the specified transmission trigger number to SCFTDR and by clearing TDFE to 0 after reading 1 from TDFE, or can be cleared by clearing TIE to 0. |
| 1 | Transmit-FIFO-data-empty interrupt request (TXI) is enabled |

Bit 6—Receive Interrupt Enable (RIE): Enables or disables the receive-data-full (RXI) and receive-error (ERI) interrupts requested when serial receive data is transferred from the receive shift register (SCRSR) to the receive FIFO data register (SCFRDR), when the quantity of data in the receive FIFO register becomes more than the specified receive trigger number, and when the RDRF flag in SCSSR is set to1.

Bit 6: RIEV. DataShDescription

| 0 | Receive-data-full interrupt (RXI), receive-error interrupt (ERI), and receive break interrupt (BRI) requests are disabled (Initial value) | | | | | |
|---|--|---|--|--|--|--|
| | RXI and ERI interrupt requests can be cleared by reading the DR, ER, or RDF flag after it has been set to 1, then clearing the flag to 0, or by clearing RIE to 0. With the RDF flag, read 1 from the RDF flag and clear it to 0, after reading receive data from SCRDR until the quantity of receive data becomes less than the specified receive trigger number. | | | | | |
| 1 | Receive-data-full interrupt (RXI) and receive-error interrupt (ERI) requests are enabled | _ | | | | |

Bit 5—Transmit Enable (TE): Enables or disables the SCIF serial transmitter.

| Bit 5: TE | Description | |
|-----------|---|-----------------|
| 0 | Transmitter disabled | (Initial value) |
| 1 | Transmitter enabled | |
| | Serial transmission starts after writing of transmit data into S transmit format in SCSMR2 and SCFCR2 and reset the TFI to 1. | |

Bit 4—Receive Enable (RE): Enables or disables the SCIF serial receiver.

| Bit 4: RE | Description | |
|-----------|--|----|
| 0 | Receiver disabled (Initial value | e) |
| | Clearing RE to 0 does not affect the receive flags (DR, ER, BRK, FER, PER, an ORER). These flags retain their previous values. | ۱d |
| 1 | Receiver enabled | |
| | Serial reception starts when a start bit is detected. Select the receive format in SCSMR2 before setting RE to 1. | |

Bits 3 and 2—Reserved: These bits are always read as 0. The write value should always be 0.

www.DataSheet4U.com Rev. 5.0, 09/03, page 565 of 806

Bits 1 and 0—Clock Enable 1 and 0 (CKE1, CKE0): Select the SCIF clock source and enable or disable clock output from the SCK pin. Depending on the combination of CKE1 and CKE0, the SCK pin can be used for serial clock output or serial clock input.

The CKE0 setting is valid only when the SCIF is operating on the internal clock (CKE1 = 0). The CKE0 setting is ignored when an external clock source is selected (CKE1 = 1). Before selecting the SCIF operating mode in the serial mode register (SCSMR), set CKE1 and CKE0. For further details on selection of the SCIF clock source, see table 17.7 in section 17.3, Operation.

| Bit 1: CKE1 | Bit 0: CKE0 | Description | |
|-------------|-------------|---|------------------------------|
| 0 | 0 | Internal clock, SCK pin used for input pin (input ignored) | signal is (Initial value) |
| | 1 | Internal clock, SCK pin used for clock output*1 | |
| 1 | 0 | External clock, SCK pin used for clock input *2 | |
| | 1 | External clock, SCK pin used for clock input *2 | |

Notes: 1. The output clock frequency is 16 times the bit rate.

2. The input clock frequency is 16 times the bit rate.

17.2.7 Serial Status Register (SCSSR)

The serial status register (SCSSR) is a 16-bit register. The upper 8 bits indicate the number of receive errors in the SCFRDR data, and the lower 8 bits indicate the SCIF operating state.

The CPU can always read and write to SCSSR, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, OPER, and DR). These flags can be cleared to 0 only if they have first been read (after being set to 1). Bits 3 (FER) and 2 (PER) are read-only bits that cannot be written. SCSSR is initialized to H'0060 by a reset and in standby or module standby mode.

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|--------|----------------|---------------|-------------------|-----------------------|---------------------------|--|
| ER | TEND | TDFE | BRK | FER | PER | RDF | DR |
| 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/(W)* | R/(W)* | R/(W)* | R/(W)* | R | R | R/(W)* | R/(W)* |
| | 0 | ER TEND 0 1 | ERTENDTDFE011 | ERTENDTDFEBRK0110 | ERTENDTDFEBRKFER01100 | ERTENDTDFEBRKFERPER011000 | ER TEND TDFE BRK FER PER RDF 0 1 1 0 0 0 0 |

Note: * The only value that can be written is 0 to clear the flag.

Bit 7—Receive Error (ER): Indicates the occurrence of a framing error, or of a parity error when receiving data that includes parity.

| Bit 7: ER | Description |
|-----------|--|
| 0 | Receiving is in progress or has ended normally ^{*1} (Initial value) |
| | ER is cleared to 0 when the chip is reset or enters standby mode, or when 0 is ^{DataSh} written after 1 is read from ER |
| 1 | A framing error or parity error has occurred |
| | ER is set to 1 when the stop bit is 0 after checking whether or not the last stop bit of the received data is 1 at the end of one data receive operation ^{*2} , or when the total number of 1s in the receive data plus parity bit does not match the even/odd parity specified by the O/\overline{E} bit in SCSMR |
| Notes: 1. | Clearing the RE bit to 0 in SCSCR does not affect the ER bit, which retains its previous value. Even if a receive error occurs, the receive data is transferred to SCFRDR and the receive operation is continued. Whether or not the data read from SCRDR includes a receive error can be detected by the FER and PER bits in SCSSR. |

2. In stop mode, only the first stop bit is checked; the second stop bit is not checked.

Bit 6—Transmit End (TEND): Indicates that when the last bit of a serial character was transmitted, SCFTDR did not contain valid data, so transmission has ended.

| Bit 6: TEND | Description | | | | | |
|-------------|---|-----------------|--|--|--|--|
| 0 | Transmission is in progress | | | | | |
| | TEND is cleared to 0 when data is written in SCFTDR | | | | | |
| 1 | End of transmission (Initia | | | | | |
| | TEND is set to 1 when the chip is reset or enters standby m cleared to 0 in the serial control register (SCSCR), or when contain receive data when the last bit of a one-byte serial ch | SCFTDR does not | | | | |

Bit 5—Transmit FIFO Data Empty (TDFE): Indicates that data has been transferred from the transmit FIFO data register (SCFTDR) to the transmit shift register (SCTSR), the quantity of data in SCFTDR has become less than the transmission trigger number specified by the TTRG1 and TTRG0 bits in the FIFO control register (SCFCR), and writing of transmit data to SCFTDR is enabled.

Bit 5: TDFE DataSDescription

| 0 | The quantity of transmit data written to SCFTDR is greater than the specified transmission trigger number (Initial value) |
|---------|--|
| | TDFE is cleared to 0 when data exceeding the specified transmission trigger number is written to SCFTDR, or when software reads TDFE after it has been set to 1, then writes 0 to TDFE |
| 1 | The quantity of transmit data in SCFTDR is less than the specified transmission trigger number $\!\!\!\!\!*$ |
| | TDFE is set to 1 by a reset or in standby mode, or when the quantity of transmit data in SCFTDR becomes less than the specified transmission trigger number as a result of transmission |
| Note: * | Since SCFTDR is a 16-byte FIFO register, the maximum quantity of data that can be |

Note: * Since SCFTDR is a 16-byte FIFO register, the maximum quantity of data that can be written when TDFE is 1 is "16 minus the specified transmission trigger number". If an attempt is made to write additional data, the data is ignored. The quantity of data in SCFTDR is indicated by the upper 8 bits of SCFTDR.

Bit 4—Break Detection (BRK): Indicates that a break signal has been detected in receive data.

| Bit 4: BRK | Description | |
|------------|---|-----------------|
| 0 | No break signal received | (Initial value) |
| | BRK is cleared to 0 when the chip is reset or enters standby mod software reads BRK after it has been set to 1, then writes 0 to BR | , |
| 1 | Break signal received* | |
| | BRK is set to 1 when data including a framing error is received, a error occurs with space 0 in the subsequent receive data | nd a framing |

Note: * When a break is detected, transfer of the receive data (H'00) to SCFRDR stops after detection. When the break ends and the receive signal becomes mark 1, the transfer of receive data resumes. The receive data of a frame in which a break signal is detected is transferred to SCFRDR. After this, however, no receive data is transferred until a break ends with the received signal being mark 1, and the next data is received.

www.DataSheet4U.com

Bit 3—Framing Error (FER): Indicates a framing error in the data read from the receive FIFO data register (SCFRDR).

| Bit 3: FER | Description |
|------------|---|
| 0 | No receive framing error occurred in the data read from SCFRDR (Initial value) |
| www.Data | FER is cleared to 0 when the chip undergoes a power-on reset or enters standby ^{Sh} mode, or when no framing error is present in the data read from SCFRDR |
| 1 | A receive framing error occurred in the data read from SCFRDR |
| | FER is set to 1 when a framing error is present in the data read from SCFRDR |

Bit 2—Parity Error (PER): Indicates a parity error in the data read from the receive FIFO data register (SCFRDR).

| Bit 2: PER | Description |
|------------|--|
| 0 | No receive parity error occurred in the data read from SCFRDR (Initial value) |
| | PER is cleared to 0 when the chip undergoes a power-on reset or enters standby mode, or when no parity error is present in the data read from SCFRDR |
| 1 | A receive framing error occurred in the data read from SCFRDR |
| | PER is set to 1 when a parity error is present in the data read from SCFRDR |

Bit 1—Receive FIFO Data Full (RDF): Indicates that receive data has been transferred to the receive FIFO data register (SCFRDR), and the quantity of data in SCFRDR has become equal or greater than the receive trigger number specified by the RTRG1 and RTRG0 bits in the FIFO control register (SCFCR).

| Bit 1: RDF | Description |
|---------------|---|
| 0 | The quantity of transmit data written to SCFRDR is less than the specified receive trigger number (Initial value) |
| | When, after a power-on reset or in the standby mode, the quantity of receive data in SCFRDR is less than the specified receive trigger value and 1 is read from RDF, which is then cleared to 0 |
| 1 | The quantity of receive data in SCFRDR is equal or greater than the specified receive trigger number |
| | RDF is set to 1 when a quantity of receive data equal or greater than the specified receive trigger number is stored in SCFRDR* |
| Note: * Since | SCFTDR is a 16-byte FIFO register, the maximum quantity of data that can be read |

Note: * Since SCFTDR is a 16-byte FIFO register, the maximum quantity of data that can be read when RDF is 1 is the specified receive trigger number. If an attempt is made to read after all the data in SCFRDR has been read, the data is undefined. The quantity of receive data in SCFRDR is indicated by the lower 8 bits of SCFTDR.

Bit 0—Receive Data Ready (DR): Indicates that the quantity of data in the receive FIFO data register (SCFRDR) is less than the specified receive trigger number, and that the next data has not yet been received after the elapse of 15 etu from the last stop bit.

| Bit 0: DR | Description | | | | | | | |
|------------|---|--|--|--|--|--|--|--|
| 0 www.[| Receiving is in progress, or no receive data remains in SCFRDR after receiving DataSended normally (Initial value) | | | | | | | |
| | DR is cleared to 0 when the chip undergoes a power-on reset or enters standby mode, or when software reads DR after it has been set to 1, then writes 0 to DR | | | | | | | |
| 1 | Next receive data has not been received | | | | | | | |
| | DR is set to 1 when SCFRDR contains less data than the specified receive trigger number, and the next data has not yet been received after the elapse of 15 etu from the last stop bit* | | | | | | | |
| | | | | | | | | |

Note: * This is equivalent to 1.5 frames with the 8-bit, 1-stop-bit format. (etu: elementary time unit)

| Upper 8 bits: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|------|------|------|------|------|------|------|------|
| | PER3 | PER2 | PER1 | PER0 | FER3 | FER2 | FER1 | FER0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |

Bits 15 to 12—Number of Parity Errors 3 to 0 (PER3 to PER0): Indicate the quantity of data including a parity error in the receive data stored in the receive FIFO data register (SCFRDR). The value indicated by bits 15 to 12 represents the number of parity errors in SCFRDR.

Bits 11 to 8—Number of Framing Errors 3 to 0 (FER3 to FER0): Indicate the quantity of data including a framing error in the receive data stored in SCFRDR. The value indicated by bits 11 to 8 represents the number of framing errors in SCFRDR.

17.2.8 Bit Rate Register (SCBRR)

The bit rate register (SCBRR) is an 8-bit register that, together with the baud rate generator clock source selected by the CKS1 and CKS0 bits in the serial mode register (SCSMR), determines the serial transmit/receive bit rate.

The CPU can always read and write to SCBRR. SCBRR is initialized to H'FF by a reset and in module standby or standby mode. Each channel has independent baud rate generator control, so different values can be set in two channels.

The SCBRR setting is calculated as follows:

Asynchronous mode:

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

- B: Bit rate (bits/s)
- N: SCBRR setting for baud rate generator ($0 \le N \le 255$)
- Po: Operating frequency for peripheral modules (MHz)
- n: Baud rate generator clock source (n = 0, 1, 2, 3) (for the clock sources and values of n, see table 17.3.)

Table 17.3SCSMR Settings

| | | SCSMR Settings | | | | | | |
|---|--------------|----------------|------|--|--|--|--|--|
| n | Clock Source | CKS1 | CKS0 | | | | | |
| 0 | Ρφ | 0 | 0 | | | | | |
| 1 | Ρφ/4 | 0 | 1 | | | | | |
| 2 | Pø/16 | 1 | 0 | | | | | |
| 3 | Ρφ/64 | 1 | 1 | | | | | |

Note: The bit rate error is given by the following formula:

Error (%) =
$$\left\{\frac{P\phi}{(N+1)\times 64\times 2^{2n-1}\times B}\times 10^6 - 1\right\}\times 100$$

www.DataSheet4U.com Rev. 5.0, 09/03, page 571 of 806

RENESAS

Table 17.4 lists examples of SCBRR settings.

 Maximum Bit Rates with External Clock Input (Asynchronous Mode)

17.2.9 FIFO Control Register (SCFCR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-------|-------|-----|-------|-------|------|
| | RTRG1 | RTRG0 | TTRG1 | TTRG0 | MCE | TFRST | RFRST | LOOP |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| www.DataShe | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

The FIFO control register (SCFCR) resets the quantity of data in the transmit and receive FIFO registers, sets the trigger data quantity, and contains an enable bit for loop-back testing. SCFCR can always be read and written to by the CPU. It is initialized to H'00 by a reset, by the module standby function, and in standby mode.

Bits 7 and 6—Receive FIFO Data Trigger (RTRG1, RTRG0): Set the quantity of receive data which sets the receive data full (RDF) flag in the serial status register (SCSSR). The RDF flag is set when the quantity of receive data stored in the receive FIFO register (SCFRDR) becomes equal or greater than the set trigger number shown below.

| Bit 7: RTRG1 | Bit 6: RTRG0 | Receive Trigger Number | |
|--------------|--------------|------------------------|-----------------|
| 0 | 0 | 1 | (Initial value) |
| 0 | 1 | 4 | |
| 1 | 0 | 8 | |
| 1 | 1 | 14 | |

Bits 5 and 4—Transmit FIFO Data Trigger (TTRG1, TTRG0): Set the quantity of remaining transmit data which sets the transmit FIFO data register empty (TDFE) flag in the serial status register (SCSSR). The TDFE flag is set when the quantity of transmit data in the transmit FIFO data register (SCFTDR) becomes less than the set trigger number shown below.

| Bit 5: TTRG1 | Bit 4: TTRG0 | Transmit Trigger Number |
|--------------|--------------|-------------------------|
| 0 | 0 | 8 (8)* |
| 0 | 1 | 4 (12) |
| 1 | 0 | 2 (14) |
| 1 | 1 | 1 (15) |

Note: * Initial value. Values in parentheses mean the number of empty bits in SCFTDR when the TDFE flag is set to 1.

Bit 3—Modem Control Enable (MCE): Enables modem control signals CTS and RTS.

| Bit 3: MCE | Description | |
|------------|------------------------------------|-----------------|
| 0 | Modem signal disabled [*] | (Initial value) |
| 1 | Modem signal enabled | |

Note: * CTS is fixed at active 0 regardless of the input value, and RTS is also fixed at 0.

Bit 2—Transmit FIFO Data Register Reset (TFRST): Disables the transmit data in the transmit FIFO data register and resets the data to the empty state.

Bit 2: TFRST Description

| 0 | Reset operation disabled* | (Initial value) |
|---|---------------------------|-----------------|
| 1 | Reset operation enabled | |
| | | |

Note: * Reset is executed in a reset or in standby mode.

Bit 1—Receive FIFO Data Register Reset (RFRST): Disables the receive data in the receive FIFO data register and resets the data to the empty state.

Bit 1: RFRST Description

| 0 | Reset operation disabled* | (Initial value) | | | | |
|---|---------------------------|-----------------|--|--|--|--|
| 1 | Reset operation enabled | | | | | |
| Nate: * Departie executed in a react or in standby made | | | | | | |

Note: * Reset is executed in a reset or in standby mode.

Bit 0—Loop-Back Test (LOOP): Internally connects the transmit output pin (TXD) and receive input pin (RXD) and enables loop-back testing.

| Bit 0: LOOP | Description | |
|-------------|-------------------------|-----------------|
| 0 | Loop back test disabled | (Initial value) |
| 1 | Loop back test enabled | |

17.2.10 FIFO Data Count Register (SCFDR)

SCFDR is a 16-bit register which indicates the quantity of data stored in the transmit FIFO data register (SCFTDR) and the receive FIFO data register (SCFRDR). It indicates the quantity of transmit data in SCFTDR with the upper 8 bits, and the quantity of receive data in SCFRDR with the lower 8 bits. SCFDR can always be read by the CPU.

| | et4U.com | | | | | | | | |
|----------------|----------|----|----|----|----|----|----|----|--|
| Upper 8 Bits: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | |
| | | _ | _ | T4 | Т3 | T2 | T1 | T0 | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |
| R/W: | R | R | R | R | R | R | R | R | |

The upper 8 bits of SCFDR indicate the quantity of non-transmitted data stored in SCFTDR. H'00 means no transmit data, and H'10 means that SCFTDR is full of transmit data.

| Lower 8 Bits: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|---|---|---|----|----|----|----|----|
| | — | _ | _ | R4 | R3 | R2 | R1 | R0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |

The lower 8 bits of SCFDR indicate the quantity of receive data stored in SCFRDR. H'00 means no receive data, and H'10 means that SCFRDR full of receive data.

17.3 Operation

17.3.1 Overview

For serial communication, the SCIF has an asynchronous mode in which characters are synchronized individually. Refer to section 15.3.2, Operation in Asynchronous Mode. The SCIF has a 16-byte FIFO buffer for both transmit and receive operations, reducing the overhead of the CPU, and enabling continuous high-speed communication. Moreover, it has $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ signals as modem control signals. The transmission format is selected in the serial mode register (SCSMR), as shown in table 17.7. The SCI clock source is selected by the combination of the CKE1 and CKE0 bits in the serial control register (SCSCR), as shown in table 17.8.

- Data length is selectable: 7 or 8 bits.
- Parity and multiprocessor bits are selectable, as is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors (FER), parity errors (PER), receive FIFO data full, receive data ready, and breaks.
- In transmitting, it is possible to detect transmit FIFO data empty.
- The number of stored data bytes is indicated for both the transmit and receive FIFO registers.
- An internal or external clock can be selected as the SCIF clock source.
 - When an internal clock is selected, the SCIF operates using the on-chip baud rate generator, and can output a serial clock signal with a frequency 16 times the bit rate.
 - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

| | | 5 | SCSMR S | Settings | SCIF Communication Format | | |
|--------------|--------------|-------------|---------------|----------------|---------------------------|-----------------|--|
| Mode | Bit 6 CHR | Bit 5 PE | Bit 3 STOP | Data Length | Parity Bit | Stop Bit Length | |

Table 17.8 SCSCR Settings and SCIF Clock Source Selection

17.3.2 Serial Operation

Transmit/Receive Formats: Table 17.9 lists the eight communication formats that can be selected. The format is selected by settings in the serial mode register (SCSMR).

| S | SCSMR Bits | | | Serial Transmit/Receive Format and Frame Length | | | | | | | | | | |
|-----|------------|------|-------|---|---|----|--------|-------|----|---|------|------|------|------|
| CHR | PE | STOP | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 0 | 0 | 0 | START | | | | 8-b | it da | ta | | | STOP |] | |
| 0 | 0 | 1 | START | | | | 8-b | it da | ta | | | STOP | STOP | |
| 0 | 1 | 0 | START | | | | 8-b | it da | ta | | | Р | STOP | |
| 0 | 1 | 1 | START | | | | 8-b | it da | ta | | | Р | STOP | STOP |
| 1 | 0 | 0 | START | | | 7- | bit da | ata | | | STOP | | | |
| 1 | 0 | 1 | START | | | 7- | bit da | ata | | | STOP | STOP | | |
| 1 | 1 | 0 | START | | | 7- | bit da | ata | | | Р | STOP | | |
| 1 | 1 | 1 | START | | | 7- | bit da | ata | | | Р | STOP | STOP | |

START: Start bit

STOP: Stop bit

P: Parity bit

Clock: An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCIF transmit/receive clock. The clock source is selected by bits CKE1 and CKE0 in the serial control register (SCSCR) (table 17.8).

When an external clock is input at the SCK pin, it must have a frequency equal to 16 times the desired bit rate.

www.DataSheet4U.com

When the SCIF operates on an internal clock, it can output a clock signal at the SCK pin. The frequency of this output clock is 16 times the bit rate.

Transmitting and Receiving Data (SCIF Initialization): Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCIF as follows.

When changing the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing TE and RE to 0, however, does not initialize the serial status register (SCSSR), transmit FIFO data register (SCFTDR), or receive FIFO data register (SCFRDR), which retain their previous contents. Clear TE to 0 after all transmit data has been transmitted and the TEND flag in the SCSSR is set. The TE bit can be cleared to 0 during transmission, but the transmit data goes to the high impedance state after the bit is cleared to 0. Set the TFRST bit in SCFCR to 1 and reset SCFTDR before TE is set again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIF operation becomes unreliable if the clock is stopped.

Figure 17.5 shows a sample flowchart for initializing the SCIF. The procedure for initializing the SCIF is:

1. Set the clock selection in SCSCR.

Be sure to clear bits RIE TIE, TE, and RE to 0.

When clock output is selected, the clock is output immediately after SCSCR settings are made.

- 2. Set the communication format in SCSMR.
- Write a value corresponding to the bit rate into the bit rate register (SCBRR). (Not necessary if an external clock is used.)
- 4. Wait at least one bit interval, then set the TE bit or RE bit in SCSCR to 1. Also set the RIE and TIE bits.

Setting the TE and RE bits enables the TxD and RxD pins to be used. When transmitting, the SCIF will go to the mark state; when receiving, it will go to the idle state, waiting for a start bit.

www.DataSheet4U.com Rev. 5.0, 09/03, page 583 of 806

Figure 17.5 Sample Flowchart for SCIF Initialization

• Serial data transmission

Figure 17.6 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling the SCIF for transmission.

1. SCIF status check and transmit data write:

Read serial status register (SCSSR) and check that the TDFE flag is set to 1, then write transmit data to the transmit FIFO data register (SCFTDR), read 1 from the TDFE and TEND flags, then clear these flags to 0.

The number of transmit data bytes that can be written is (16 - transmit trigger set number).

2. Serial transmission continuation procedure:

To continue serial transmission, read 1 from the TDFE flag to confirm that writing is possible, then write data to SCFTDR, and then clear the TDFE flag to 0.

3. Break output at the end of serial transmission:

To output a break in serial transmission, set the port SC data register (SCPDR) and port SC control register (SCPCR), then clear the TE bit to 0 in the serial control register (SCSCR). For information on SCPDR and SCPCR, see section 17.2.8, Bit Rate Register (SCBRR).

In steps 1 and 2, it is possible to ascertain the number of data bytes that can be written from the number of transmit data bytes in SCFTDR indicated by the upper 8 bits of the FIFO data count register (SCFDR).

Figure 17.6 Sample Flowchart for Transmitting Serial Data

www.DataSheet4U.com

RENESAS

In serial transmission, the SCIF operates as described below.

- 1. When data is written into the transmit FIFO data register (SCFTDR), the SCIF transfers the data from SCFTDR to the transmit shift register (SCTSR) and starts transmitting. Confirm that the TDFE flag in the serial status register (SCSSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 transmit trigger setting). www.DataSheet4U.com
- 2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

The serial transmit data is sent from the TxD pin in the following order.

- a. Start bit: One-bit 0 is output.
- b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
- c. Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
- d. Stop bit(s): One or two 1-bits (stop bits) are output.
- e. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
- 3. The SCIF checks the SCFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCSSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output continuously.

4. When modem control is enabled, transmission can be stopped and restarted in accordance with the CTS input value. When CTS is set to 1, if transmission is in progress, the line goes to the mark state after transmission of one frame. When CTS is set to 0, the next transmit data is output starting from the start bit.

Figure 17.8 shows an example of the operation when modem control is used.

Figure 17.8 Example of Operation Using Modem Control (CTS)

www.DataSheet4U.com

• Serial data reception

Figures 17.9 and 17.10 show a sample flowchart for serial reception.

Use the following procedure for serial data reception after enabling the SCIF for reception.

- 1. Receive error handling and break detection: Read the DR, ER, and BRK flags in SCSSR to identify any error, perform the appropriate error handling, then clear the DR, ER, and BRK flags to 0. In the case of a framing error, a break can also be detected by reading the value of the RxD pin.
- 2. SCIF status check and receive data read: Read the serial status register (SCSSR) and check that RDF = 1, then read the receive data in the receive FIFO data register (SCFRDR), read 1 from the RDF flag, and then clear the RDF flag to 0. The transition of the RDF flag from 0 to 1 can be identified by an RXI interrupt.
- 3. Serial reception continuation procedure: To continue serial reception, read at least the receive trigger set number of receive data bytes from SCFRDR, read 1 from the RDF flag, then clear the RDF flag to 0. The number of receive data bytes in SCFRDR can be ascertained by reading the lower bits of SCFDR.

Figure 17.9 Sample Flowchart for Receiving Serial Data

- 1. Whether a framing error or parity error has occurred in the receive data read from SCFRDR can be ascertained from the FER and PER bits in SCSSR.
- 2. When a break signal is received, receive data is not transferred to SCFRDR while the BRK flag is set. However, note that the last data in SCFRDR is H'00 and the break data in which a framing error occurred is stored.

www.DataSheet4U.com

Figure 17.10 Sample Flowchart for Receiving Serial Data (cont)

RENESAS

In serial reception, the SCIF operates as described below.

- 1. The SCIF monitors the transmission line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
- 2. The received data is stored in SCRSR in LSB-to-MSB order.
- www.DataSheet4U.com
- The parity bit and stop bit are received. After receiving these bits, the SCIF carries out the following checks.
 - a. Stop bit check: The SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
 - b. The SCIF checks whether receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
 - c. Break check: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.

If all the above checks are passed, the receive data is stored in SCFRDR.

Note: Reception is not suspended when a receive error occurs.

4. If the RIE bit in SCSR is set to 1 when the RDF or DR flag changes to 1, a receive-FIFO-datafull interrupt (RXI) request is generated.

If the RIE bit in SCSR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the RIE bit in SCSR is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

Figure 17.11 shows an example of the operation for reception.

Figure 17.11 Example of SCIF Receive Operation (8-Bit Data, Parity, One Stop Bit)

5. When modem control is enabled, the $\overline{\text{RTS}}$ signal is output when SCFRDR is empty. When $\overline{\text{RTS}}$ is 0, reception is possible. When $\overline{\text{RTS}}$ is 1, this indicates that SCFRDR is full and reception is not possible.

Figure 17.12 shows an example of the operation when modem control is used.

Figure 17.12 Example of Operation Using Modem Control (RTS)

RENESAS

17.4 SCIF Interrupts

The SCIF has four interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive-data-full (RXI), and break (BRI).

Table 17.10 shows the interrupt sources and their order of priority. The interrupt sources are enabled or disabled by means of the TIE and RIE bits in SCSCR. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When the TDFE flag in the serial status register (SCSSR) is set to 1, a TXI interrupt request is generated. The DMAC can be activated and data transfer performed when this interrupt is generated. When data exceeding the transmit trigger number is written to the transmit data register (SCFTDR) by the DMAC, 1 is read from the TDFE flag, after which 0 is written to it to clear it.

When the RDF flag in SCSSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed when the RDF flag in SCSSR is set to 1. When receive data less than the receive trigger number is read from the receive data register (SCFRDR) by the DMAC, 1 is read from the RDF flag, after which 0 is written to it to clear it.

When the ER flag in SCSSR is set to 1, an ERI interrupt request is generated.

When the BRK flag in SCSSR is set to 1, a BRI interrupt request is generated.

The TXI interrupt indicates that transmit data can be written, and the RXI interrupt indicates that there is receive data in SCFRDR.

| Interrupt Source | Description | DMAC Activation | Priority |
|---------------------|--|------------------------|----------|
| ERI | Interrupt initiated by receive error flag (ER) | Not possible | High |
| RXI | Interrupt initiated by receive data FIFO full flag (RDF) or data ready flag (DR) | Possible (RDF only) | ↑ |
| BRI | Interrupt initiated by break flag (BRK) | Not possible | _ |
| ТХІ | Interrupt initiated by transmit FIFO data empty flag (TDFE) | Possible | Low |

Table 17.10 SCIF Interrupt Sources

See section 4, Exception Handling, for priorities and the relationship to non-SCIF interrupts.

17.5 Usage Notes

Note the following when using the SCIF.

1. SCFTDR Writing and TDFE Flag: The TDFE flag in the serial status register (SCSSR) is set when the number of transmit data bytes written in the transmit FIFO data register (SCFTDR) has fallen below the transmit trigger number set by bits TTRG1 and TTRG0 in the FIFO control register (SCFCR). After TDFE is set, transmit data up to the number of empty bytes in SCFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written to SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again even after having been cleared to 0. TDFE clearing should therefore be carried out after data exceeding the specified transmit trigger number has been written to SCFTDR.

The number of transmit data bytes in SCFTDR can be found from the upper 8 bits of the FIFO data count register (SCFDR).

2. SCFRDR Reading and RDF Flag: The RDF flag in the serial status register (SCSSR) is set when the number of receive data bytes in the receive FIFO data register (SCFRDR) has become equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in the FIFO control register (SCFCR). After RDF is set, receive data equivalent to the trigger number can be read from SCFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCFRDR is equal to or greater than the trigger number, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all the receive data has been read.

The number of receive data bytes in SCFRDR can be found from the lower 8 bits of the FIFO data count register (SCFDR).

3. Break Detection and Processing: Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state the input from the RxD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set. Note that, although transfer of receive data to SCFRDR is halted in the break state, the SCIF receiver continues to operate, so if the BRK flag is cleared to 0 it will be set to 1 again.

4. Sending a Break Signal: The I/O condition and level of the TxD pin are determined by the SCP4DT bit in the port SC data register (SCPDR) and bits SCP4MD0 and SCP4MD1 in the port SC control register (SCPCR). This feature can be used to send a break signal. To send a break signal during serial transmission, clear the CP4DT bit to 0 (designating low level), then set the SCP4MD0 and SCP4MD1 bits to 0 and 1, respectively, and finally clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD pin.

www.DataSheet4U.com Rev. 5.0, 09/03, page 595 of 806

5. TEND Flag and TE Bit Processing: The TEND flag is set to 1 during transmission of the stop bit of the last data. Consequently, if the TE bit is cleared to 0 immediately after setting of the TEND flag has been confirmed, the stop bit will be in the process of transmission and will not be transmitted normally. Therefore, the TE bit should not be cleared to 0 for at least 0.5 serial clock cycles (or 1.5 cycles if two stop bits are used) after setting of the TEND flag is confirmed.

6. Receive Data Sampling Timing and Receive Margin: The SCIF operates on a base clock with a frequency of 16 times the transfer rate. In reception, the SCIF synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse. The timing is shown in figure 17.13.

Figure 17.13 Receive Data Sampling Timing in Asynchronous Mode

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

Equation 1:

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where: M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

- D: Clock duty cycle (D = 0 to 1.0)
- L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

www.DataSheet4U.com

Rev. 5.0, 09/03, page 596 of 806

Equation 2:

When D = 0.5 and F = 0:

 $\begin{array}{ll} M &= (0.5-1/(2\times 16))\times 100\% \\ &= 46.875\% \end{array}$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

Section 18 IrDA

18.1 Overview

The SH7729R has an on-chip Infrared Data Association (IrDA) interface which is based on the IrDA 1.0 system and can perform infrared communication. It also can be used as the SCIF by making register settings.

18.1.1 Features

- Conforms to the IrDA 1.0 system
- Asynchronous serial communication
 - Data length: 8 bits
 - Stop bit length: 1 bit
 - Parity bit: None
- On-chip 16-stage FIFO buffers for both transmit and receive operations
- On-chip baud rate generator with selectable bit rates
- Guard functions to protect the receiver during transmission
- Clock supply halted to reduce power consumption when not using the IrDA interface

18.1.2 Block Diagram

Figure 18.1 shows a block diagram of the IrDA.

Figure 18.1 Block Diagram of IrDA

www.DataSheet4U.com

Figures 18.2 to 18.4 show the IrDA I/O port pins.

SCIF pin I/O and data control is performed by bits 7 to 4 of SCPCR and bits 3 and 2 of SCPDR. For details, see section 15.2.8, SC Port Control Register (SCPCR)/SC Port Data Register (SCPDR).

Figure 18.2 SCPT[3]/SCK1 Pin

www.DataSheet4U.com Rev. 5.0, 09/03, page 601 of 806

Figure 18.3 SCPT[2]/TxD1 Pin

18.1.3 Pin Configuration

The IrDA has the serial pins summarized in table 18.1.

Table 18.1 IrDA Pins

| Pin Name | Signal Name | I/O | Function |
|-------------------|-------------|--------|----------------------|
| Serial clock pin | SCK1 | I/O | Clock I/O |
| Receive data pin | RxD1 | Input | Receive data input |
| Transmit data pin | TxD1 | Output | Transmit data output |

Note: Clock input from the serial clock pin cannot be set in IrDA mode.

18.1.4 Register Configuration

The IrDA has the internal registers shown in table 18.2. These registers select IrDA or SCIF mode, specify the data format and a bit rate, and control the transmit and receive units.

Table 18.2 IrDA Registers

ww.DataSheet4U.com

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|-------------------------------|--------------|---------|---------------|--|----------------|
| Serial mode register 1 | SCSMR1 | R/W | H'00 | H'04000140 (H'A4000140) ^{*2} | 8 bits |
| Bit rate register 1 | SCBRR1 | R/W | H'FF | H'04000142 (H'A4000142) ^{*2} | 8 bits |
| Serial control register 1 | SCSCR1 | R/W | H'00 | H'04000144 (H'A4000144) ^{*2} | 8 bits |
| Transmit FIFO data register 1 | SCFTDR1 | W | — | H'04000146 (H'A4000146) ^{*2} | 8 bits |
| Serial status register 1 | SCSSR1 | R/(W)*1 | H'0060 | H'04000148 (H'A4000148) ^{*2} | 16 bits |
| Receive FIFO data register 1 | SCFRDR1 | R | Undefined | H'0400014A (H'A400014A) ^{*2} | 8 bits |
| FIFO control register 1 | SCFCR1 | R/W | H'00 | H'0400014C (H'A400014C) ^{*2} | 8 bits |
| FIFO data count register 1 | SCFDR1 | R | H'0000 | H'0400014E (H'A400014E) ^{*2} | 16 bits |

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

- 1. Only 0 can be written to clear the flag.
- 2. When address translation by the MMU does not apply, the address in parentheses should be used.

.

18.2 Register Description

Specifications of the registers in the IrDA are the same as those in the SCIF except for the serial mode register described below. Therefore, refer to section 17, Serial Communication Interface with FIFO (SCIF), for details of these registers.

vww.DataSheet4U.com

18.2.1 Serial Mode Register (SCSMR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|------|------|------|------|------|------|------|
| | IRMOD | ICK3 | ICK2 | ICK1 | ICK0 | PSEL | CKS1 | CKS0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

SCSMR is an 8-bit register that selects IrDA or SCIF mode, specifies the SCIF serial communication format, selects the IrDA output pulse width, and selects the baud rate generator clock source.

This module operates as IrDA when the IRMOD bit is set to 1. At this time, bits 3 to 6 are fixed at 0. This register functions in the same way as the SCSMR register in the SCIF when the IRMOD bit is cleared to 0; therefore, this module can also operate as an SCIF.

SCSMR is initialized to H'00 by a power-on reset or manual reset, when the module is stopped by the module standby function, and in standby mode.

Bit 7—IrDA Mode (IRMOD): Selects whether this module operates as an IrDA serial communication interface or as an SCIF.

| Bit 7: IRMOD | Description |
|--------------|-------------|
|--------------|-------------|

| 0 | Operates as an SCIF | (Initial value) | | | |
|------|--|-----------------|--|--|--|
| 1* | Operates as an IrDA | | | | |
| Noto | Note: * Do not set the CKE1 bit in the social control register (SCSCPT) to 1 if the IPMCD bit is set | | | | |

Note: * Do not set the CKE1 bit in the serial control register (SCSCRT) to 1 if the IRMCD bit is set to 1.

Bits 6 to 3—Ir Clock Select Bits (ICK3 to ICK0)

Bit 2—Output Pulse Width Select (PSEL): PSEL selects an IrDA output pulse width that is 3/16 of the bit length for 115 kbps or 3/16 of the bit length for the selected baud rate.

The Ir clock select bits should be set properly to fix the output pulse width at 3/16 of the bit length for 115 kbps by setting the PSEL bit to 1.

| Bit 6: ICK3 | Bit 5: ICK2 | Bit 4: ICK1 | Bit 3: ICK0 | Bit 2: PSEL | Description |
|----------------|----------------|----------------|----------------|----------------|--|
| ICK3 | ICK2 | ICK1 | ICK0 | 1 | Pulse width: 3/16 of 115 kbps bit length |
| Don't care | Don't care | Don't care | Don't care | 0 | Pulse width: 3/16 of bit length |

It is necessary to generate a fixed clock pulse, IRCLK, by dividing the P ϕ clock by 1/2N + 2 (with the value of N determined by the setting of ICK3–ICK0).

Example:

P
 clock: 14.7456 MHz

IRCLK: 921.6 kHz (fixed)

N: Setting of ICK3–ICK0 ($0 \le N \le 15$)

$$N \geq \frac{P \varphi}{2XIRCLK} - 1 \geq 7$$

Accordingly, N is 7.

Bits 1 and 0—Clock Select 1 and 0 (CKS1, CKS0): Select the internal baud rate generator clock source. P ϕ , P ϕ /4, P ϕ /16, or P ϕ /64 can be selected by setting the CKS1 and CKS0 bits.

Refer to section 15.2.9, Bit Rate Register (SCBRR), for the relationship between the clock source, the bit rate register set value, and the baud rate.

| Bit 1: CKS1 | Bit 0: CKS0 | Description | |
|-------------|-------------|-------------|-----------------|
| 0 | 0 | Pø clock | (Initial value) |
| 0 | 1 | Pø/4 clock | |
| 1 | 0 | Ρφ/16 | |
| 1 | 1 | Ρφ/64 | |

Note: Po: Peripheral clock

18.3 Operation Description

The IrDA module can perform infrared communication conforming to IrDA 1.0 by connecting infrared transmit/receive units. The serial communication interface unit includes a 16-stage FIFO buffer in the transmit unit and the receive unit, allowing CPU overhead to be reduced and continuous high-speed communication to be performed. This module also supports DMAC data transfer. The IrDA module differs from the SCIF described in section 17, Serial Communication Interface with FIFO (SCIF) in that it does not include modem control signals RTS and CTS.

Refer to section 17.3, Operation, for SCIF mode operation.

18.3.1 Overview

The IrDA module modifies TxD/RxD transmit/receive data waveforms to satisfy the IrDA 1.0 specification for infrared communication.

In the IrDA 1.0 specification, communication is first performed at a speed of 9600 bps, and the communication speed is changed. However, the communication rate cannot be automatically changed in this module, so the communication speed should be confirmed, and the appropriate speed set for this module by software.

Note: In IrDA mode, reception cannot be performed when the TE bit in the serial control register (SCSCR) is set to 1 (enabling transmission). When performing reception, clear the TE bit in SCSCR to 0.
As the SH7729R's RxD1 pin is active-high in IrDA mode, a (Schmidt) inverter must be inserted when connecting an active-low IrDA module.
The RxD1 pin is active-low in SCIF mode.

18.3.2 Transmitting

In the case of a serial output signal (UART frame) from the SCIF, its waveforms are modified and the signal is converted into the IR frame serial output signal by the IrDA module, as shown in figure 18.5.

When serial data is 0, a pulse of 3/16 the IR frame bit width is generated and output. When serial data is 1, no pulse is output.

An infrared LED is driven by this signal demodulated to 3/16 width.

www.DataSheet4U.com Rev. 5.0, 09/03, page 607 of 806

18.3.3 Receiving

Received 3/16 IR frame bit-width pulses are demodulated and converted to a UART frame, as shown in figure 18.5.

Demodulation to 0 is performed for pulse output, and demodulation to 1 is performed for no pulse output.

Figure 18.5 Transmit/Receive Operation

Section 19 Pin Function Controller

19.1 Overview

The pin function controller (PFC) is composed of registers for selecting the function of multiplexed pins and the input/output direction. The pin function and input/output direction can be selected for each pin individually without regard to the operating mode of the chip. Table 19.1 lists the multiplexed pins.

| Port | Port Function (Related Module) | Other Function (Related Module) |
|------|---|------------------------------------|
| А | PTA7 input/output (port) | D23 input/output (data bus) |
| А | PTA6 input/output (port) | D22 input/output (data bus) |
| А | PTA5 input/output (port) | D21 input/output (data bus) |
| А | PTA4 input/output (port) | D20 input/output (data bus) |
| А | PTA3 input/output (port) | D19 input/output (data bus) |
| А | PTA2 input/output (port) | D18 input/output (data bus) |
| А | PTA1 input/output (port) | D17 input/output (data bus) |
| А | PTA0 input/output (port) | D16 input/output (data bus) |

| SC port control register | SCPCR | R/W | H'A888 | H'04000116 (H'A4000116) [*] | 16 |

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

The initial value of the port E, F, G, and H control registers depends on the state of the ASEMD0 pin.

If a low level is input at the ASEMDO pin while the RESETP pin is asserted, ASE mode is entered; if a high level is input, normal mode is entered. See section 23, User Debugging Interface (UDI), for more information on the UDI.

* When address translation by the MMU does not apply, the address in parentheses should be used.

19.3 Register Descriptions

19.3.1 Port A Control Register (PACR)

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | PA7 | PA7 | PA6 | PA6 | PA5 | PA5 | PA4 | PA4 | PA3 | PA3 | PA2 | PA2 | PA1 | PA1 | PA0 | PA0 |
| | MD1 | MD0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W |

The port A control register (PACR) is a 16-bit readable/writable register that selects the pin functions. PACR is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset, in standby mode, or in sleep mode.

Bits 15 and 14—PA7 Mode 1 and 0 (PA7MD1, PA7MD0) Bits 13 and 12—PA6 Mode 1 and 0 (PA6MD1, PA6MD0) Bits 11 and 10—PA5 Mode 1 and 0 (PA5MD1, PA5MD0) Bits 9 and 8—PA4 Mode 1 and 0 (PA4MD1, PA4MD0) Bits 7 and 6—PA3 Mode 1 and 0 (PA3MD1, PA3MD0) Bits 5 and 4—PA2 Mode 1 and 0 (PA2MD1, PA2MD0) Bits 3 and 2—PA1 Mode 1 and 0 (PA1MD1, PA1MD0) Bits 1 and 0—PA0 Mode 1 and 0 (PA0MD1, PA0MD0)

These bits select the pin functions and perform input pull-up MOS control.

| Bit (211 1 1) | Dit Lii | | |

19.3.2 Port B Control Register (PBCR)

The port B control register (PBCR) is a 16-bit readable/writable register that selects the pin functions. PBCR is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset, in standby mode, or in sleep mode.

Bits 15 and 14—PB7 Mode 1 and 0 (PB7MD1, PB7MD0) Bits 13 and 12—PB6 Mode 1 and 0 (PB6MD1, PB6MD0) Bits 11 and 10—PB5 Mode 1 and 0 (PB5MD1, PB5MD0) Bits 9 and 8—PB4 Mode 1 and 0 (PB4MD1, PB4MD0) Bits 7 and 6—PB3 Mode 1 and 0 (PB3MD1, PB3MD0) Bits 5 and 4—PB2 Mode 1 and 0 (PB2MD1, PB2MD0) Bits 3 and 2—PB1 Mode 1 and 0 (PB1MD1, PB1MD0) Bits 1 and 0—PB0 Mode 1 and 0 (PB0MD1, PB0MD0)

These bits select the pin functions and perform input pull-up MOS control.

| Bit (2n + 1) | Bit 2n | | |
|--------------|--------|---------------------------------|-----------------|

19.3.3 Port C Control Register (PCCR)

The port C control register (PCCR) is a 16-bit readable/writable register that selects the pin functions. PCCR is initialized to H'AAAA by a power-on reset, but is not initialized by a manual reset, in standby mode, or in sleep mode.

Bits 15 and 14—PC7 Mode 1 and 0 (PC7MD1, PC7MD0) Bits 13 and 12—PB6 Mode 1 and 0 (PC6MD1, PC6MD0) Bits 11 and 10—PC5 Mode 1 and 0 (PC5MD1, PC5MD0) Bits 9 and 8—PC4 Mode 1 and 0 (PC4MD1, PC4MD0) Bits 7 and 6—PC3 Mode 1 and 0 (PC3MD1, PC3MD0) Bits 5 and 4—PC2 Mode 1 and 0 (PC2MD1, PC2MD0) Bits 3 and 2—PC1 Mode 1 and 0 (PC1MD1, PC1MD0) Bits 1 and 0—PC0 Mode 1 and 0 (PC0MD1, PC0MD0)

These bits select the pin functions and perform input pull-up MOS control.

| Bit (2n + 1) | Bit 2n | | |

19.3.4 Port D Control Register (PDCR)

The port D control register (PDCR) is a 16-bit readable/writable register that selects the pin functions. PDCR is initialized to H'AA8A by a power-on reset, but is not initialized by a manual reset, in standby mode, or in sleep mode.

Bits 15 and 14—PD7 Mode 1 and 0 (PD7MD1, PD7MD0) Bits 11 and 10—PD5 Mode 1 and 0 (PD5MD1, PD5MD0) Bits 7 and 6—PD3 Mode 1 and 0 (PD3MD1, PD3MD0) Bits 5 and 4—PD2 Mode 1 and 0 (PD2MD1, PD2MD0) Bits 3 and 2—PD1 Mode 1 and 0 (PD1MD1, PD1MD0) Bits 1 and 0—PD0 Mode 1 and 0 (PD0MD1, PD0MD0)

Dit (0m + 4) Dit 0m

These bits select the pin functions and perform input pull-up MOS control.

19.3.5 Port E Control Register (PECR)

The port E control register (PECR) is a 16-bit readable/writable register that selects the pin functions. PECR is initialized to H'AAAA ($\overline{ASEMD0} = 1$) or H'2AA8 ($\overline{ASEMD0} = 0$) by a power-on reset, but is not initialized by a manual reset, in software standby mode, or in sleep mode.

Bits 15 and 14—PE7 Mode 1 and 0 (PE7MD1, PE7MD0) Bits 13 and 12—PE6 Mode 1 and 0 (PE6MD1, PE6MD0) Bits 11 and 10—PE5 Mode 1 and 0 (PE5MD1, PE5MD0) Bits 9 and 8—PE4 Mode 1 and 0 (PE4MD1, PE4MD0) Bits 7 and 6—PE3 Mode 1 and 0 (PE3MD1, PE3MD0) Bits 5 and 4—PE2 Mode 1 and 0 (PE2MD1, PE2MD0) Bits 3 and 2—PE1 Mode 1 and 0 (PE1MD1, PE1MD0) Bits 1 and 0—PE0 Mode 1 and 0 (PE0MD1, PE0MD0) These bits select the pin functions and perform input pull-up MOS control.

The SC port control register (SCPCR) is a 16-bit readable/writable register that selects the pin functions. The setting of SCPCR is valid only when transmit/receive operations are disabled in the SCSCR register. SCPCR is initialized to H'A888 by a power-on reset, but is not initialized by a manual reset, in standby mode, or in sleep mode. When the TE bit in SCSCR is set to 1, the "other function" output state has a higher priority than the SCPCR setting for the TxD[2:0] pins. When the RE bit in SCSCR is set to 1, the input state has a higher priority than the SCPCR setting for the RxD[2:0] pins.

Bits 15 and 14—SCP7 Mode 1 and 0 (SCP7MD1, SCP7MD0): These bits select the pin function and perform input pull-up MOS control.

| Bit 15 | Bit 14 | | |
|---------|---------|---------------------------------|-----------------|
| SCP7MD1 | SCP7MD0 | Pin Function | |
| 0 | 0 | Other function (see table 19.1) | |
| 0 | 1 | Reserved | |
| 1 | 0 | Port input (Pull-up MOS: on) | (Initial value) |
| 1 | 1 | Port input (Pull-up MOS: off) | |

Bits 13, 12—SCP6 Mode 1, 0 (SCP6MD1, SCP6MD0): These bits select the pin function and perform input pull-up MOS control.

Section 20 I/O Ports

20.1 Overview

The SH7729R has twelve 8-bit ports (ports A to L and SC). All port pins are multiplexed with other pin functions (the pin function controller (PFC) handles the selection of pin functions and pull-up MOS control). Each port has a data register which stores data for the pins.

20.2 Port A

Port A is an 8-bit input/output port with the pin configuration shown in figure 20.1. Each pin has an input pull-up MOS, which is controlled by the port A control register (PACR) in the PFC.

Figure 20.1 Port A

20.2.1 Register Description

Table 20.1 summarizes the port A register.

Table 20.1 Port A Register

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------|--------------|-----|---------------|-----------------------------|-------------|
| Port A data register | PADR | R/W | H'00 | H'04000120 (H'A4000120)* | 8 |

Notes: This register is located in area 1 of physical space. Therefore, when the cache is on, either access this register from the P2 area of logical space or else make an appropriate setting using the MMU so that this register is not cached.

* When address translation by the MMU does not apply, the address in parentheses should be used.

20.2.2 Port A Data Register (PADR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------------------|--------------------|-------|-------|-------|-------|-------|-------|-------|
| | PA7DT | PA6DT | PA5DT | PA4DT | PA3DT | PA2DT | PA1DT | PA0DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| www.D RW he | eet4 R/W /m | R/W |

The port A data register (PADR) is an 8-bit readable/writable register that stores data for pins PTA7 to PTA0. Bits PA7DT to PA0DT correspond to pins PTA7 to PTA0. When the pin function is general output port, if the port is read the value of the corresponding PADR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read. Table 20.2 shows the function of PADR.

PADR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Table 20.2 | Port A Data Register (PADR) Read/Write Operations | |
|-------------------|---|--|
|-------------------|---|--|

| PAnMD1 | PAnMD0 | Pin State | Read | Write |
|--------|--------|---------------------------------|------------|---|
| 0 | 0 | Other function (See table 19.1) | PADR value | Value is written to PADR, but does not affect pin state |
| | 1 | Output | PADR value | Write value is output from pin. |
| 1 | 0 | Input (Pull-up MOS on) | Pin state | Value is written to PADR, but does not affect pin state |
| | 1 | Input (Pull-up MOS off) | Pin state | Value is written to PADR, but does not affect pin state |
| - | | | | |

(n = 7 to 0)

20.3 Port B

Port B is an 8-bit input/output port with the pin configuration shown in figure 20.2. Each pin has an input pull-up MOS, which is controlled by the port B control register (PBCR) in the PFC.

Figure 20.2 Port B

20.3.1 Register Description

Table 20.3 summarizes the port B register.

Table 20.3Port B Register

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------|--------------|-----|---------------|-----------------------------|-------------|
| Port B data register | PBDR | R/W | H'00 | H'04000122 (H'A4000122)* | 8 |

Notes: This register is located in area 1 of physical space. Therefore, when the cache is on, either access this register from the P2 area of logical space or else make an appropriate setting using the MMU so that this register is not cached.

* When address translation by the MMU does not apply, the address in parentheses should be used.

20.3.2 Port B Data Register (PBDR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | PB7DT | PB6DT | PB5DT | PB4DT | PB3DT | PB2DT | PB1DT | PB0DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| www.DataShe | R/W |

The port B data register (PBDR) is an 8-bit readable/writable register that stores data for pins PTB7 to PTB0. Bits PB7DT to PB0DT correspond to pins PTB7 to PTB0. When the pin function is general output port, if the port is read the value of the corresponding PBDR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read. Table 20.4 shows the function of PBDR.

PBDR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| PBnMD1 | PBnMD0 | Pin State | Read | Write |
|--------|--------|---------------------------------|------------|---|
| 0 | 0 | Other function (See table 19.1) | PBDR value | Value is written to PBDR, but does not affect pin state |
| | 1 | Output | PBDR value | Write value is output from pin |
| 1 | 0 | Input (Pull-up MOS on) | Pin state | Value is written to PBDR, but does not affect pin state |
| | 1 | Input (Pull-up MOS off) | Pin state | Value is written to PBDR, but does not affect pin state |
| | | | | |

| Table 20.4 | Port B Data Register (PBDR) Read/Write Operations |
|-------------------|---|
|-------------------|---|

(n = 7 to 0)

20.4 Port C

Port C is an 8-bit input/output port with the pin configuration shown in figure 20.3. Each pin has an input pull-up MOS, which is controlled by the port C control register (PCCR) in the PFC.

Figure 20.3 Port C

20.4.1 Register Description

Table 20.5 summarizes the port C register.

Table 20.5 Port C Register

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------|--------------|-----|---------------|-----------------------------|-------------|
| Port C data register | PCDR | R/W | H'00 | H'04000124 (H'A4000124)* | 8 |

Notes: This register is located in area 1 of physical space. Therefore, when the cache is on, either access this register from the P2 area of logical space or else make an appropriate setting using the MMU so that this register is not cached.

* When address translation by the MMU does not apply, the address in parentheses should be used.

20.4.2 Port C Data Register (PCDR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | PC7DT | PC6DT | PC5DT | PC4DT | PC3DT | PC2DT | PC1DT | PC0DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| www.DataShe | R/W |

The port C data register (PCDR) is an 8-bit readable/writable register that stores data for pins PTC7 to PTC0. Bits PC7DT to PC0DT correspond to pins PTC7 to PTC0. When the pin function is general output port, if the port is read, the value of the corresponding PCDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read. Table 20.6 shows the function of PCDR.

PCDR is initialized to H'00 by a power-on reset, after which the general input port function (pullup MOS on) is set as the initial pin function, and the corresponding pin levels are read.

| PCnMD1 | PCnMD0 | Pin State | Read | Write |
|--------|--------|---------------------------------|------------|---|
| 0 | 0 | Other function (See table 19.1) | PCDR value | Value is written to PCDR, but does not affect pin state |
| | 1 | Output | PCDR value | Write value is output from pin |

Table 20.6 Port C Data Register (PCDR) Read/Write Operations

(n = 7 to 0)

20.5 Port D

Port D comprises a 6-bit input/output port and 2-bit input port with the pin configuration shown in figure 20.4. Each pin has an input pull-up MOS, which is controlled by the port D control register (PDCR) in the PFC.

Figure 20.4 Port D

20.5.1 Register Description

Table 20.7 summarizes the port D register.

Table 20.7 Port D Register

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------|--------------|----------|---------------|--|-------------|
| Port D data register | PDDR | R/W or R | B'0*0*0000 | H'04000126 (H'A4000126) ^{*1} | 8 |

Notes: This register is located in area 1 of physical space. Therefore, when the cache is on, either access this register from the P2 area of logical space or else make an appropriate setting using the MMU so that this register is not cached.

- * Means no value.
- 1. When address translation by the MMU does not apply, the address in parentheses should be used.

20.5.2 Port D Data Register (PDDR)

| | Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | | PD7DT | PD6DT | PD5DT | PD4DT | PD3DT | PD2DT | PD1DT | PD0DT |
| | Initial value: | 0 | * | 0 | * | 0 | 0 | 0 | 0 |
| | www.DataShe | R/W | R | R/W | R | R/W | R/W | R/W | R/W |
| Note: | * Undefined | | | | | | | | |

The port D data register (PDDR) is a 6-bit readable/writable and 2-bit read-only register that stores data for pins PTD7 to PTD0. Bits PD7DT to PD0DT correspond to pins PTD7 to PTD0. When the pin function is general output port, if the port is read, the value of the corresponding PDDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read. Table 20.8 shows the function of PDDR.

PDDR is initialized to B'0*0*0000 by a power-on reset. After initialization, the general input port function (pull-up MOS on) is set as the initial pin function, and the corresponding pin levels are read from bits PD7DT—PD3DT, PD1DT, and PD0DT. PDDR retains its previous value in standby mode and sleep mode, and in a manual reset.

Note that the low level is read if bits 6 and 4 are read except in general-purpose input.

| PDnMD0 | Pin State | Read | Write |
|--------|---------------------------------|---|--|

20.6 Port E

Port E is an 8-bit input/output port with the pin configuration shown in figure 20.5. Each pin has an input pull-up MOS, which is controlled by the port E control register (PECR) in the PFC.

Figure 20.5 Port E

20.6.1 Register Description

Table 20.9 summarizes the port E register.

Table 20.9Port E Register

| Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|----------------------|--------------|-----|---------------|---|-------------|
| Port E data register | PEDR | R/W | H'00 | H'04000128 (H'A4000128) [*] | 8 |

Notes: This register is located in area 1 of physical space. Therefore, when the cache is on, either access this register from the P2 area of logical space or else make an appropriate setting using the MMU so that this register is not cached.

* When address translation by the MMU does not apply, the address in parentheses should be used.

20.6.2 Port E Data Register (PEDR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | PE7DT | PE6DT | PE5DT | PE4DT | PE3DT | PE2DT | PE1DT | PE0DT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| www.DataShe | R/W |

The port E data register (PEDR) is an 8-bit readable/writable register that stores data for pins PTE7 to PTE0. Bits PE7DT to PE0DT correspond to pins PTE7 to PTE0. When the pin function is general output port, if the port is read the value of the corresponding PEDR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read. Table 20.10 shows the function of PEDR.

PEDR is initialized to H'00 by a power-on reset, after which the general input port function (pullup MOS on) is set as the initial pin function, and the corresponding pin levels are read. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| e * Undefined | | | | | | | | |

Note: * Undefined

The SC port data register (SCPDR) is a 7-bit readable/writable and 1-bit read-only register that stores data for pins SCPT7 to SCPT0. Bits SCP7DT to SCP0DT correspond to pins SCPT7 to SCPT0. When the pin function is general output port, if the port is read, the value of the corresponding SCPDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read. Table 20.24 shows the function of SCPDR.

SCPDR is initialized to B'*0000000 by a power-on reset. After initialization, the general input port function (pull-up MOS on) is set as the initial pin function, and the corresponding pin levels are read from bits SCP7DT—SCP5DT, SCP3DT, and SCP1DT. SCPDR retains its previous value in standby mode and sleep mode, and in a manual reset.

Note that the low level is read if bit 7 is read except in general-purpose input.

Section 21 A/D Converter

21.1 Overview

The SH7729R includes a 10-bit successive-approximation A/D converter allowing selection of up to eight analog input channels.

21.1.1 Features

A/D converter features are listed below.

- 10-bit resolution
- Eight input channels
- High-speed conversion
 - Conversion time: maximum 15 μ s per channel (P ϕ = 33 MHz operation)
- Three conversion modes
 - Single mode: A/D conversion on one channel
 - Multi mode: A/D conversion on one to four channels
 - Scan mode: Continuous A/D conversion on one to four channels
- Four 16-bit data registers
 - A/D conversion results are transferred for storage into data registers corresponding to the channels.
- Sample-and-hold function
- A/D conversion can be externally triggered
- A/D interrupt requested at the end of conversion
 - At the end of A/D conversion, an A/D end interrupt (ADI) can be requested.

21.1.2 Block Diagram

21.1.3 Input Pins

Table 21.1 summarizes the A/D converter's input pins. The eight analog input pins are divided into two groups: group 0 (AN0 to AN3), and group 1 (AN4 to AN7). AVCC and AVSS are the power supply inputs for the analog circuits in the A/D converter. AVcc also functions as the A/D converter reference voltage pin.

www.DataSheet4U.com

Table 21.1A/D Converter Pins

| Pin Name | Abbreviation | I/O | Function |
|-----------------------------------|--------------|-------|--|
| Analog power supply pin | AVcc | Input | Analog power supply |
| Analog ground pin | AVss | Input | Analog ground and reference voltage |

| A/D control/status register | ADCSR | R/(W)*1 | H'00 | H'04000090 (H'A4000090) ^{*2} | 8 |
| A/D control register | ADCR | R/W | H'3F | H'04000092 (H'A4000092) ^{*2} | 8 |

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

- 1. Only 0 can be written to bit 7, to clear the flag.
- 2. When address translation by the MMU does not apply, the address in parentheses should be used.

21.2 Register Descriptions

21.2.1 A/D Data Registers A to D (ADDRA to ADDRD)

n = A to D

The four A/D data registers (ADDRA to ADDRD) are 16-bit read-only registers that store the results of A/D conversion.

An A/D conversion produces 10-bit data, which is transferred for storage into the A/D data register corresponding to the selected channel. The upper 8 bits of the result are stored in the upper byte (bits 15 to 8) of the A/D data register. The lower 2 bits are stored in the lower byte (bits 7 and 6). Bits 5 to 0 of an A/D data register are reserved bits that are always read as 0. Table 21.3 indicates the pairings of analog input channels and A/D data registers.

The A/D data registers are initialized to H'0000 by a reset and in standby mode.

Table 21.3 Analog Input Channels and A/D Data Registers

| | Analog Input Channel | | |
|---------|----------------------|-------------------|--|
| Group 0 | Group 1 | A/D Data Register | |
| AN0 | AN4 | ADDRA | |
| AN1 | AN5 | ADDRB | |
| AN2 | AN6 | ADDRC | |
| AN3 | AN7 | ADDRD | |

21.2.2 A/D Control/Status Register (ADCSR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------------------------------|--------|------|------|-------|-----|-----|-----|-----|
| | ADF | ADIE | ADST | MULTI | CKS | CH2 | CH1 | CH0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | R/(W)* | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Note: * Write 0 to clear the flag. | | | | | | | | |

ADCSR is an 8-bit readable/writable register that selects the mode and controls the A/D converter. ADCSR is initialized to H'00 by a reset and in standby mode.

Bit 7—A/D End Flag (ADF): Indicates the end of A/D conversion.

| Bit 7: ADF | Description | | | | |
|------------|--|-----------------|--|--|--|
| 0 | [Clearing conditions] | (Initial value) | | | |
| | (1) Cleared by reading ADF while $ADF = 1$, then writing 0 to ADF | | | | |
| | (2) Cleared when DMAC is activated by ADI interrupt and ADDR is rea | | | | |
| 1 | [Setting conditions] | | | | |
| | Single mode: A/D conversion ends | | | | |
| | Multi mode: A/D conversion ends on all selected channels | | | | |

Bit 6—A/D Interrupt Enable (ADIE): Enables or disables the interrupt (ADI) requested at the end of A/D conversion.

| Bit 6: ADIE | Description | |
|-------------|---|-----------------|
| 0 | A/D end interrupt request (ADI) is disabled | (Initial value) |
| 1 | A/D end interrupt request (ADI) is enabled | |

Bit 5—A/D Start (ADST): Starts or stops A/D conversion. The ADST bit remains set to 1 during A/D conversion. It can also be set to 1 by external trigger input at the ADTRG pin.

| Bit 5: ADST | Description | |
|-------------|--|-----------------|
| 0 | A/D conversion is stopped | (Initial value) |
| 1 | Single mode: A/D conversion starts; ADST is automatically cleare conversion ends | d to 0 when |
| | Scan mode: A/D conversion starts and continues, cycling through channels, until ADST is cleared to 0 by software, by a reset, or by standby mode | |

www.DataSheet4U.com

Bit 4—Multi Mode (MULTI): Selects single mode, multi mode or scan mode. For further information on operation in these modes, see section 21.4, Operation.

| Bit 4: | MULTI | ADCR: Bit5: SCN | Description | |
|--------|-----------|-------------------|-------------|-----------------|
| 0 | | — | Single mode | (Initial value) |
| 1 | MANA Data | 0 Shoot4LL.com | Multi mode | |
| | | 1 | scan mode | |

Bit 3—Clock Select (CKS): Selects the A/D conversion time. Clear the ADST bit to 0 before changing the conversion time.

| Bit 3:CKS | Description | |
|-----------|--|-----------------|
| 0 | Conversion time = 536 states (maximum) | (Initial value) |
| 1 | Conversion time = 266 states (maximum) | |

Bits 2 to 0—Channel Select 2 to 0 (CH2 to CH0): These bits and the MULTI bit select the analog input channels. Clear the ADST bit to 0 before changing the channel selection.

| | Channel Sele | ction | DescriptionSingle ModeMulti Mode(MULTI = 0)(MULTI = 1) | | |
|-----|--------------|-------|---|------------|--|
| CH2 | CH1 | CH0 | - | | |
| 0 | 0 | 0 | AN0 (Initial value) | AN0 | |
| | | 1 | Single Mode (MULTI = 0)AN0 (Initial value)AN1AN2AN3AN4AN5AN6 | AN0, AN1 | |
| | 1 | 0 | AN2 | AN0 to AN2 | |
| | | 1 | AN3 | AN0 to AN3 | |
| 1 | 0 | 0 | AN4 | AN4 | |
| | | 1 | AN5 | AN4, AN5 | |
| | 1 | 0 | AN6 | AN4 to AN6 | |
| | | 1 | AN7 | AN4 to AN7 | |

21.2.3 A/D Control Register (ADCR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|------------|---------|-----|--------|--------|---|---|---|
| | TRGE1 | TRGE0 | SCN | RESVD1 | RESVD2 | _ | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
| R/W: | taSheet4U. | com R/W | R/W | R/W | R/W | R | R | R |

ADCR is an 8-bit readable/writable register that enables or disables external triggering of A/D conversion. ADCR is initialized to H'07 by a reset and in standby mode.

Bits 7 and 6—Trigger Enable (TRGE1, TRGE0): Enables or disables external triggering of A/D conversion.

The TRGE1 and TRGE0 bits should only be set when conversion is not in progress.

| Bit 7: TRGE1 | Bit 6: TRGE0 | Description |
|--------------|--------------|---|
| 0 | 0 | A/D conversion does not start when an external trigger is input |
| 0 | 1 | (Initial value) |
| 1 | 0 | A/D conversion starts at the falling edge of an input signal from |
| 1 | 1 | the external trigger pin (ADTRG) |

Bit 5—Scan Mode (SCN): Selects multi mode or scan mode when the MULTI bit is set to 1. See the description of bit 4 in section 21.2.2, A/D Control/Status Register (ADCSR).

Bits 4 and 3—Reserved (RESVD1, RESVD2): These bits are always read as 0. The write value should always be 0.

Bits 2 to 0—Reserved: These bits are always read as 1. The write value should always be 1.

www.DataSheet4U.com

21.3 Bus Master Interface

ADDRA to ADDRD are 16-bit registers, but they are connected to the bus master by the upper 8 bits of the 16-bit peripheral data bus. Therefore, although the upper byte can be accessed directly by the bus master, the lower byte is read through an 8-bit temporary register (TEMP).

An A/D data register is read as follows. When the upper byte is read, the upper-byte value is transferred directly to the bus master and the lower-byte value is transferred into TEMP. Next, when the lower byte is read, the TEMP contents are transferred to the bus master.

When reading an A/D data register, always read the upper byte before the lower byte. It is possible to read only the upper byte, but if only the lower byte is read, the read value is not guaranteed.

Figure 21.2 shows the data flow for access to an A/D data register.

See section 21.7.3, Access Size and Read Data.

Figure 21.2 A/D Data Register Access Operation (Reading H'AA40)

21.4 Operation

The A/D converter operates by successive approximations with 10-bit resolution. It has three operating modes: single mode, multi mode, and scan mode.

21.4.1 Single Mode (MULTI = 0)

Single mode should be selected when only one A/D conversion on one channel is required. A/D conversion starts when the ADST bit is set to 1 by software, or by external trigger input. The ADST bit remains set to 1 during A/D conversion and is automatically cleared to 0 when conversion ends.

When conversion ends the ADF bit is set to 1. If the ADIE bit is also set to 1, an ADI interrupt is requested at this time. To clear the ADF flag to 0, first read ADCSR, then write 0 to ADF.

When the mode or analog input channel must be switched during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 in ADCSR to halt A/D conversion. After making the necessary changes, set the ADST bit to 1 to start A/D conversion again. The ADST bit can be set at the same time as the mode or channel is changed.

Typical operations when channel 1 (AN1) is selected in single mode are described next.

Figure 21.3 shows a timing diagram for this example.

- 1. Single mode is selected (MULTI = 0), input channel AN1 is selected (CH2 = CH1 = 0, CH0 = 1), the A/D interrupt is enabled (ADIE = 1), and A/D conversion is started (ADST = 1).
- 2. When A/D conversion is completed, the result is transferred into ADDRB. At the same time the ADF flag is set to 1, the ADST bit is cleared to 0, and the A/D converter becomes idle.
- 3. Since ADF = 1 and ADIE = 1, an ADI interrupt is requested.
- 4. The A/D interrupt handling routine starts.
- 5. The routine reads ADCSR, then writes 0 to the ADF flag.
- 6. The routine reads and processes the conversion result (ADDRB = 0).
- 7. Execution of the A/D interrupt handling routine ends. Then, when the ADST bit is set to 1, A/D conversion starts and steps 2 to 7 are executed.

Figure 21.3 Example of A/D Converter Operation (Single Mode, Channel 1 Selected)

21.4.2 Multi Mode (MULTI = 1, SCN = 0)

Multi mode should be selected when performing A/D conversions on one or more channels. When the ADST bit is set to 1 by software or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0, AN4 when CH2 = 1). When two or more channels are selected, after conversion of the first channel ends, conversion of the second channel (AN1 or AN5) starts immediately. When A/D conversions end on the selected channels, the ADST bit is cleared to 0. The conversion results are transferred for storage into the A/D data registers corresponding to the channels.

When the mode or analog input channel selection must be changed during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 in ADCSR to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels in group 0 (AN0 to AN2) are selected in scan mode are described next. Figure 21.4 shows a timing diagram for this example.

- 1. Multi mode is selected (MULTI = 1), channel group 0 is selected (CH2 = 0), analog input channels AN0 to AN2 are selected (CH1 = 1, CH0 = 0), and A/D conversion is started (ADST = 1).
- 2. When A/D conversion of the first channel (AN0) is completed, the result is transferred into ADDRA. Next, conversion of the second channel (AN1) starts automatically.
- 3. Conversion proceeds in the same way through the third channel (AN2).
- 4. When conversion of all selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and ADST bit is cleared to 0. If the ADIE bit is set to 1, an ADI interrupt is requested at this time.

Figure 21.4 Example of A/D Converter Operation (Multi Mode, Channels AN0 to AN2 Selected)

www.DataSheet4U.com Rev. 5.0, 09/03, page 669 of 806

21.4.3 Scan Mode (MULTI = 1, SCN = 1)

Scan mode is useful for monitoring analog inputs in a group of one or more channels. When the ADST bit in the A/D control/status register (ADCSR) is set to 1 by software or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0, AN4 when CH2 = 1)). When two or more channels are selected, after conversion of the first channel ends, conversion of the second channel (AN1 or AN5) starts immediately. A/D conversion continues cyclically on the selected channels until the ADST bit is cleared to 0. The conversion results are transferred for storage into the A/D data registers corresponding to the channels.

When the mode or analog input channel must be changed during analog conversion, to prevent incorrect operation, first clear the ADST bit to 0 to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels (AN0 to AN2) are selected in scan mode are described next. Figure 21.5 shows a timing diagram for this example.

- 1. Scan mode is selected (MULTI = 1, SCN = 1), channel group 2 is selected (CH2 = 0), analog input channels AN0 to AN2 are selected (CH1 = 1, CH0 = 0), and A/D conversion is started (ADST = 1).
- 2. When A/D conversion of the first channel (AN0) is completed, the result is transferred into ADDRA. Next, conversion of the second channel (AN1) starts automatically.
- 3. Conversion proceeds in the same way through the third channel (AN2).
- 4. When conversion of all the selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and conversion of the first channel (AN0) starts again. If the ADIE bit is set to 1, an ADI interrupt is requested at this time.
- 5. Steps 2 to 4 are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops. After that, if the ADST bit is set to 1, A/D conversion starts again from the first channel (AN0).

Figure 21.5 Example of A/D Converter Operation (Scan Mode, Channels AN0 to AN2 Selected)

21.4.4 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input at a time t_D after the ADST bit is set to 1, then starts conversion. Figure 21.6 shows the A/D conversion timing. Table 21.4 indicates the A/D conversion time.

As indicated in figure 21.6, the A/D conversion time includes t_D and the input sampling time. The length of t_D varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 21.4.

In multi mode and scan mode, the conversion time values given in table 21.4 apply to the first conversion. In the second and subsequent conversions, the conversion time is fixed at 256 states when CKS = 0 in ADCSR, or 128 states when CKS = 1. In both cases, the CKS bit should be set according to the P ϕ frequency so that the conversion time is within the range shown in table 24.10 in section 24, Electrical Characteristics.

Figure 21.6 A/D Conversion Timing

| Input sampling time | t _{SPL} | _ | 129 | _ | — | 65 | _ |
| A/D conversion time | t _{CONV} | 514 | | 525 | 259 | _ | 266 |

Table 21.4 A/D Conversion Time (Single Mode)

Note: Values in the table are numbers of states (t_{cyc}) .

21.4.5 External Trigger Input Timing

A/D conversion can be externally triggered. When the TRGE1 and TRGE0 bits are set to 1 in ADCR, external trigger input is enabled at the ADTRG pin. A high-to-low transition at the ADTRG pin sets the ADST bit to 1 in ADCSR, starting A/D conversion. Other operations, regardless of the conversion mode, are the same as if the ADST bit had been set to 1 by software. Figure 21.7 shows the timing.

Figure 21.7 External Trigger Input Timing

21.5 Interrupts

The A/D converter generates an interrupt (ADI) at the end of A/D conversion. The ADI interrupt request can be enabled or disabled by the ADIE bit in ADCSR.

21.6 Definitions of A/D Conversion Accuracy

The A/D converter compares an analog value input from an analog input channel with its analog reference value and converts it to 10-bit digital data. The absolute accuracy of this A/D conversion is the deviation between the input analog value and the output digital value. It includes the following errors:

- Offset error
- Full-scale error
- Quantization error
- Nonlinearity error

These four error quantities are explained below with reference to figure 21.8. In the figure, the 10 bits of the A/D converter have been simplified to 3 bits.

Offset error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the minimum (zero voltage) 000000000 (000 in the figure) to 000000001 (001 in the figure)(figure 21.8, item (1)). Full-scale error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the 111111110 (110 in the figure) to the maximum 1111111111 (111 in the figure)(figure 21.8, item (2)). Quantization error is the intrinsic error of the A/D converter and is expressed as 1/2 LSB (figure 21.8, item (3)). Nonlinearity error is the deviation between actual and ideal A/D conversion characteristics between zero voltage and full-scale voltage (figure 21.8, item (4)). Note that it does not include offset, full-scale, or quantization error.

Figure 21.8 Definitions of A/D Conversion Accuracy

21.7 Usage Notes

When using the A/D converter, note the following points.

21.7.1 Setting Analog Input Voltage

- Analog Input Voltage Range: During A/D conversion, the voltages input to the analog input pins ANn should be in the range $AV_{SS} \le ANn \le AV_{CC}$ (n = 0 to 7).
- Relationships of AV_{CC} and AV_{SS} to V_{CC} and V_{SS}: AV_{CC}, AV_{SS}, V_{CC} and V_{SS} should be related as follows: $AV_{CC} = V_{CC} \pm 0.3$ V and $AV_{SS} = V_{SS}$.

21.7.2 Processing of Analog Input Pins

To prevent damage from voltage surges at the analog input pins (AN0 to AN7), connect an input protection circuit like the one shown in figure 21.9. The circuit shown also includes an RC filter to suppress noise. This circuit is shown as an example; the circuit constants should be selected according to actual application conditions. Table 21.5 lists the analog input pin specifications and figure 21.10 shows an equivalent circuit diagram of the analog input ports.

www.DataSheet4U.com Rev. 5.0, 09/03, page 675 of 806

21.7.3 Access Size and Read Data

Table 21.6 shows the relationship between access size and read data. Note the read data obtained with different access sizes, bus widths, and endian modes.

The case is shown here in which H'3FF is obtained when AV_{CC} is input as an analog input. FF is the data containing the upper 8 bits of the conversion result, and C0 is the data containing the lower 2 bits.

Section 22 D/A Converter

22.1 Overview

The SH7729R includes a D/A converter with two channels. www.DataSheet4U.com

22.1.1 Features

D/A converter features are listed below.

- Eight-bit resolution
- Two output channels
- Conversion time: maximum 10 µs (with 20-pF capacitive load)
- Output voltage: 0 V to AVcc

22.1.2 Block Diagram

Figure 22.1 shows a block diagram of the D/A converter.

www.DataSheet4U.com Rev. 5.0, 09/03, page 679 of 806

22.1.3 I/O Pins

Table 22.1 summarizes the D/A converter's input and output pins.

Table 22.1D/A Converter Pins

| Pin Name | Abbreviation | I/O | Function |
|-------------------------|--------------|--------|-------------------------------------|
| Analog power supply pin | AVcc | Input | Analog power supply |
| Analog ground pin | AVss | Input | Analog ground and reference voltage |
| Analog output pin 0 | DA0 | Output | Analog output, channel 0 |
| Analog output pin 1 | DA1 | Output | Analog output, channel 1 |

22.1.4 Register Configuration

Table 22.2 summarizes the D/A converter's registers.

Table 22.2 D/A Converter Registers

| Name | Abbreviation | R/W | Initial Value | Address ^{*1} |
|----------------------|--------------|-----|---------------|--|
| D/A data register 0 | DADR0 | R/W | H'00 | H'040000A0 (H'A40000A0) ^{*2} |
| D/A data register 1 | DADR1 | R/W | H'00 | H'040000A2 (H'A40000A2) ^{*2} |
| D/A control register | DACR | R/W | H'1F | H'040000A4 (H'A40000A4) ^{*2} |

Notes: These registers are located in area 1 of physical space. Therefore, when the cache is on, either access these registers from the P2 area of logical space or else make an appropriate setting using the MMU so that these registers are not cached.

- 1. Lower 16 bits of the address
- 2. When address translation by the MMU does not apply, the address in parentheses should be used.

www.DataSheet4U.com

22.2 Register Descriptions

22.2.1 D/A Data Registers 0 and 1 (DADR0/1)

The D/A data registers (DADR0 and DADR1) are 8-bit readable/writable registers that store the data to be converted. When analog output is enabled, the D/A data register values are constantly converted and output at the analog output pins.

The D/A data registers are initialized to H'00 by a reset.

22.2.2 D/A Control Register (DACR)

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|-------|-------|-----|---|---|---|---|---|
| | DAOE1 | DAOE0 | DAE | _ | | _ | _ | — |
| Initial value: | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W | R/W | R/W | R | R | R | R | R |

DACR is an 8-bit readable/writable register that controls the operation of the D/A converter. DACR is initialized to H'1F by a reset.

Bit 7—D/A Output Enable 1 (DAOE1): Controls D/A conversion and analog output.

| Bit 7: DAOE1 | Description | |
|--------------|--|-----------------|
| 0 | DA1 analog output is disabled | (Initial value) |
| 1 | Channel-1 D/A conversion and DA1 analog output are enabled | |

Bit 6—D/A Output Enable 0 (DAOE0): Controls D/A conversion and analog output.

| Bit 6: DAOE0 | Description | |
|--------------|--|-----------------|
| 0 | DA0 analog output is disabled | (Initial value) |
| 1 | Channel-0 D/A conversion and DA0 analog output are enabled | |

www.DataSheet4U.com Rev. 5.0, 09/03, page 681 of 806

Bit 5—D/A Enable (DAE): Controls D/A conversion, together with bits DAOE0 and DAOE1. When the DAE bit is cleared to 0, D/A conversion is controlled independently in channels 0 and 1. When the chip enters standby mode while D/A conversion is enabled, the D/A output is held and the analog power-supply current is equivalent to that during D/A conversion. To reduce the analog power-supply current in standby mode, clear the DAOE0 and DAOE1 bits and disable the D/A output.

| Bit 7: DAOE1 | Bit 6: DAOE0 | Bit 5: DAE | Description |
|--------------|--------------|------------|---|
| 0 | 0 | _ | D/A conversion is disabled in channels 0 and 1 (Initial value) |
| 0 | 1 | 0 | D/A conversion is enabled in channel 0 |
| | | | D/A conversion is disabled in channel 1 |
| 0 | 1 | 1 | D/A conversion is enabled in channels 0 and 1 |
| 1 | 0 | 0 | D/A conversion is disabled in channel 0 |
| | | | D/A conversion is enabled in channel 1 |
| 1 | 0 | 1 | D/A conversion is enabled in channels 0 and 1 |
| 1 | 1 | _ | D/A conversion is enabled in channels 0 and 1 |

When the DAE bit is set to 1, even if bits DAOE0 and DAOE1 in DACR and the ADST bit in ADCSR are cleared to 0, the same current is drawn from the analog power supply as during A/D and D/A conversion.

Bits 4 to 0—Reserved: Read-only bits, always read as 1.

www.DataSheet4U.com

22.3 Operation

The D/A converter has two built-in D/A conversion circuits that can perform conversion independently.

D/A conversion is performed constantly while enabled in DACR. If the DADR0 or DADR1 value is modified, conversion of the new data begins immediately. The conversion results are output when bits DAOE0 and DAOE1 are set to 1.

An example of D/A conversion on channel 0 is given next. Timing is indicated in figure 22.2.

- 1. Data to be converted is written in DADR0.
- Bit DAOE0 is set to 1 in DACR. D/A conversion starts and DA0 becomes an output pin. The converted result is output after the conversion time. The output value is (DADR0 contents/256) × AVcc. Output of this conversion result continues until the value in DADR0 is modified or the DAOE0 bit is cleared to 0.
- 3. If the DADR0 value is modified, conversion starts immediately, and the result is output after the conversion time.
- 4. When the DAOE0 bit is cleared to 0, DA0 becomes an input pin.

Section 23 User Debugging Interface (UDI)

23.1 Overview

The SH7729R incorporates a user debugging interface (UDI) and advanced user debugger (AUD) for program debugging.

23.2 User Debugging Interface (UDI)

The UDI (user debugging interface) performs on-chip debugging which is supported by the SH7729R. The UDI described here is a serial interface which is compatible with JTAG (Joint Test Action Group, IEEE Standard 1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture) specifications.

The UDI in the SH7729R supports a boundary scan mode, and is also used for emulator connection.

When using an emulator, UDI functions should not be used. Refer to the emulator manual for the method of connecting the emulator.

23.2.1 Pin Descriptions

TCK: UDI serial data input/output clock pin. Data is serially supplied to the UDI from the data input pin (TDI), and output from the data output pin (TDO), in synchronization with this clock.

TMS: Mode select input pin. The state of the TAP control circuit is determined by changing this signal in synchronization with TCK. The protocol complies with the JTAG standard (IEEE Std. 1149.1).

TRST: UDI reset input pin. Input is accepted asynchronously with respect to TCK, and when low, the UDI is reset. See section 23.4.2, Reset Configuration, for more information.

TDI: UDI serial data input pin. Data transfer to the UDI is executed by changing this signal in synchronization with TCK.

TDO: UDI serial data output pin. Data output from the UDI is executed by reading this signal in synchronization with TCK.

ASEMDO: ASE mode select pin. If a low level is input at the $\overline{\text{ASEMDO}}$ pin while the $\overline{\text{RESETP}}$ pin is asserted, ASE mode is entered; if a high level is input, normal mode is entered. In ASE mode, boundary scan and emulator functions can be used. The input level at the $\overline{\text{ASEMDO}}$ pin should be held for at least one cycle after $\overline{\text{RESETP}}$ negation.

www.DataSheet4U.com Rev. 5.0, 09/03, page 685 of 806

ASEBRKAK: Dedicated emulator pin

23.2.2 Block Diagram

Figure 23.1 shows a block diagram of the UDI.

Figure 23.1 Block Diagram of UDI

23.3 Register Descriptions

The UDI has the following registers.

- SDBPR: Bypass register
- SDIR: Instruction register
- SDBSR: Boundary scan register

Table 23.1 shows the UDI register configuration.

Table 23.1UDI Registers

| | | CPU Side | | UDI Side | | Initial | |
|----------------------|--------------|----------|------|------------|-----|---------|-----------|
| Name | Abbreviation | R/W | Size | Address | R/W | Size | Value* |
| Bypass register Shee | SDBPR | _ | _ | _ | R/W | 1 | Undefined |
| Instruction register | SDIR | R | 16 | H'04000200 | R/W | 16 | H'FFFF |
| Boundary register | SDBSR | _ | _ | _ | R/W | | Undefined |

Note: * Initialized when TRST pin is low or when TAP is in the test-logic-reset state.

23.3.1 Bypass Register (SDBPR)

The bypass register is a 1-bit register that cannot be accessed by the CPU. When SDIR is set to the bypass mode, SDBPR is connected between UDI pins TDI and TDO.

23.3.2 Instruction Register (SDIR)

The instruction register (SDIR) is a 16-bit read-only register. The register is in bypass mode in its initial state. It is initialized by $\overline{\text{TRST}}$ or in the TAP test-logic-reset state, and can be written to by the UDI irrespective of the CPU mode. Operation is not guaranteed if a reserved command is set in this register

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----------------|-----|-----|-----|-----|----|----|---|---|
| | TI3 | TI2 | TI1 | TIO | — | — | — | — |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| | | | | | | | | |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | _ | — | _ | _ | _ | — | _ | — |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

Bits 15 to 12—Test Instruction Bits (TI3 to TI0): Cannot be written by the CPU.

| TI3 | TI2 | TI1 | TIO | Description |
|-----|--------------------------|-----|-----|-----------------------------|
| 0 | 0 | 0 | 0 | EXTEST |
| 0 | 1 | 0 | 0 | SAMPLE/PRELOAD |
| 0 | 1 www.DataSheet4U.com | 0 | 1 | Reserved |
| 0 | 1 | 1 | 0 | UDI reset negate |
| 0 | 1 | 1 | 1 | UDI reset assert |
| 1 | 0 | 0 | — | Reserved |
| 1 | 0 | 1 | — | UDI interrupt |
| 1 | 1 | 0 | — | Reserved |
| 1 | 1 | 1 | 0 | Reserved |
| 1 | 1 | 1 | 1 | Bypass mode (Initial value) |
| 0 | 0 | 0 | 1 | Recovery from sleep |

Table 23.2UDI Commands

Bits 11 to 0—Reserved: These bits are always read as 1.

23.3.3 Boundary Scan Register (SDBSR)

The boundary scan register (SDBSR) is a shift register, located on the PAD, for controlling the input/output pins of the SH7729R.

Using the EXTEST and SAMPLE/PRELOAD commands, a boundary scan test conforming to the JTAG standard can be carried out. Table 23.3 shows the correspondence between SH7729R pins and boundary scan register bits.

23.4 UDI Operation

23.4.1 TAP Controller

Figure 23.2 shows the internal states of the TAP controller. State transitions basically conform with the JTAG standard.com

Figure 23.2 TAP Controller State Transitions

Note: The transition condition is the TMS value at the rising edge of TCK. The TDI value is sampled at the rising edge of TCK; shifting occurs at the falling edge of TCK. The TDO value changes at the TCK falling edge. The TDO is at high impedance, except with shift-DR (shift-SR) and shift-IR states. During the change to $\overline{\text{TRST}} = 0$, there is a transition to test-logic-reset asynchronously with TCK.

23.4.2 Reset Configuration

| ASDMD0 ^{*1} | RESETP | TRST | Chip State |
|----------------------|------------|------------|---|
| High-level | Low-level | Low-level | Normal reset and UDI reset |
| www.DataSheet4U.com | | High-level | Normal reset |
| | High-level | Low-level | UDI reset only |
| | | High-level | Normal operation |
| Low-level | Low-level | Low-level | Reset hold ^{*2} |
| | | High-level | ASE user mode ^{*3} : Normal reset ASE break mode ^{*3} : RESETP assertion masked |
| | High-level | Low-level | UDI reset only |
| | | High-level | Normal operation |

Table 23.4 Reset Configuration

- Notes: 1. Performs main chip mode and ASE mode settings $\overline{\text{ASEMD0}}$ = H, main chip mode $\overline{\text{ASEMD0}}$ = L, ASE mode
 - In ASE mode, reset hold is enabled by driving the RESETP and TRST pins low for a constant cycle. In this state, the CPU does not start up, even if RESETP is driven high. When TRST is driven high, UDI operation is enabled, but the CPU does not start up. The reset hold state is cancelled by the following:
 - Boot request from UDI (boot sequence)
 - Another RESETP assert (power-on reset)
 - 3. There are two ASE modes, one for executing software in the emulator's firmware (ASE break mode) and one for executing user software (ASE user mode).

23.4.3 UDI Reset

An UDI reset is executed by setting an UDI reset assert command in SDIR. An UDI reset is of the same kind as a power-on reset. An UDI reset is released by inputting an UDI reset negate command.

Figure 23.3 UDI Reset

23.4.4 UDI Interrupt

The UDI interrupt function generates an interrupt by setting a command from the UDI in the SDIR. An UDI interrupt is a general exception/interrupt operation, resulting in a branch to an address based on the VBR value plus offset, and with return by the RTE instruction. This interrupt request has a fixed priority level of 15.

UDI interrupts are not accepted in sleep mode or standby mode.

23.4.5 Bypass

The JTAG-based bypass mode for the UDI pins can be selected by setting a command from the UDI in SDIR.

23.4.6 Using UDI to Recover from Sleep Mode

It is possible to recover from sleep mode by setting a command (0001) from the UDI in SDIR.

www.DataSheet4U.com Rev. 5.0, 09/03, page 697 of 806

23.5 Boundary Scan

A command can be set in SDIR by the UDI to place the UDI pins in the boundary scan mode stipulated by JTAG.

23.5.1 Supported Instructions

The SH7729R supports the three essential instructions defined in the JTAG standard (BYPASS, SAMPLE/PRELOAD, and EXTEST).

BYPASS: The BYPASS instruction is an essential standard instruction that operates the bypass register. This instruction shortens the shift path to speed up serial data transfer involving other chips on the printed circuit board. While this instruction is executing, the test circuit has no effect on the system circuits. The instruction code is 1111.

SAMPLE/PRELOAD: The SAMPLE/PRELOAD instruction inputs values from the SH7729R's internal circuitry to the boundary scan register, outputs values from the scan path, and loads data onto the scan path. When this instruction is executing, the SH7729R's input pin signals are transmitted directly to the internal circuitry, and internal circuit values are directly output externally from the output pins. The SH7729R's system circuits are not affected by execution of this instruction. The instruction code is 0100.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuitry, or a value to be transferred from the internal circuitry to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching is performed in synchronization with the rise of TCK in the Capture-DR state. Snapshot latching does not affect normal operation of the SH7729R.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

EXTEST: This instruction is provided to test external circuitry when the SH7729R is mounted on a printed circuit board. When this instruction is executed, output pins are used to output test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed circuit board, and input pins are used to latch test results into the boundary scan register from the printed circuit board. If testing is carried out by using the EXTEST instruction N times, the Nth test data is scanned-in when test data (N-1) is scanned out.

Data loaded into the output pin boundary scan register in the Capture-DR state is not used for external circuit testing (it is replaced by a shift operation).

The instruction code is 0000.

23.5.2 Points for Attention

www.DataSheet4U.com

- 1. Boundary scan mode covers clock-related signals (EXTAL, EXTAL2, XTAL, XTAL2, CKIO).
- 2. Boundary scan mode does not cover reset-related signals (RESETP, RESETM, CA).
- 3. Boundary scan mode does not cover UDI-related signals (TCK, TDI, TDO, TMS, TRST).
- 4. When a boundary scan test is carried out, ensure that the CKIO clock operates constantly. The CKIO frequency range is as follows:

Minimum: 1 MHz

Maximum: Maximum frequency for respective clock mode specified in the CPG section Set pins MD[2:0] to the clock mode to be used.

After powering on, wait for the CKIO clock to stabilize before performing a boundary scan test.

- 5. Fix the $\overline{\text{RESETP}}$ pin low.
- 6. Fix the CA pin high, and the $\overline{\text{ASEMD0}}$ pin low.

23.6 Usage Notes

- 1. An UDI command other than an UDI interrupt, once set, will not be modified as long as another command is not re-issued from the UDI. An UDI interrupt command, however, will be changed to a bypass command once set.
- 2. Because chip operations are suspended in standby mode, UDI commands are not accepted. However, the TAP controller remains in operation at this time.
- 3. The UDI is used for emulator connection. Therefore, UDI functions cannot be used when using an emulator.

23.7 Advanced User Debugger (AUD)

The AUD is a function exclusively for use by an emulator. Refer to the User's Manual for the relevant emulator for details of the AUD.

Section 24 Electrical Characteristics

24.1 Absolute Maximum Ratings

Table 24.1 shows the absolute maximum ratings. www.DataSheet4U.com

Table 24.1 Absolute Maximum Ratings

| Item | Symbol | Rating | Unit |
|---------------------------------|--|--------------------|------|
| Power supply voltage (I/O) | VccQ | –0.3 to 4.2 | V |
| Power supply voltage (internal) | Vcc Vcc – PLL1 Vcc – PLL2 Vcc – RTC | –0.3 to 2.5 | V |
| Input voltage (except port L) | Vin | -0.3 to VccQ + 0.3 | V |
| Input voltage (port L) | Vin | -0.3 to AVcc + 0.3 | V |
| Analog power supply voltage | AVcc | –0.3 to 4.6 | V |
| Analog input voltage | V _{AN} | -0.3 to AVcc + 0.3 | V |
| Operating temperature | Topr | -20 to 75 | °C |
| Storage temperature | Tstr | –55 to 125 | °C |

Caution: Operating the chip in excess of the absolute maximum rating may result in permanent damage.

- Order of turning on 1.7 V/1.8 V/1.9 V/2.0 V power (Vcc, Vcc-PLL1, Vcc-PLL2, Vcc-RTC) and 3.3 V power (VccQ, AVcc):
 - 1. First turn on the 3.3 V power, then turn on the 1.7 V/1.8 V/1.9 V/2.0 V power within 1 ms. This interval should be as short as possible.
 - 2. Until voltage is applied to all power supplies, a low level is input at the **RESETP** pin, and CKIO has operated for a maximum of 4 clock cycles, internal circuits remain unsettled, and so pin states are also undefined. The system design must ensure that these undefined states do not cause erroneous system operation.

Note that the $\overline{\text{RESETP}}$ pin cannot receive a low level signal while a low level signal is being input to the CA pin.

Waveforms at power-on are shown in the following figure.

www.DataSheet4U.com Rev. 5.0, 09/03, page 701 of 806

Power-On Sequence

- Power-off order
 - 1. In the reverse order of powering-on, first turn off the 1.7 V/1.8 V/1.9 V/2.0 V power, then turn off the 3.3 V power within 1 ms. This interval should be as short as possible.
 - 2. Pin states are undefined while only the 1.7 V/1.8 V/1.9 V/2.0 V power is off. The system design must ensure that these undefined states do not cause erroneous system operation.

24.2 DC Characteristics

Tables 24.2 and 24.3 list the DC characteristics.

Notes: When the PLL circuits are not used, connect Vcc-PLL1 and Vcc-PLL2 to Vcc, and Vss-PLL1 and Vss-PLL2 to Vss.

Power must be supplied between Vcc-RTC and Vss-RTC even if the RTC is not used. AVcc conditions must be: VccQ – 0.3 V \leq AVcc \leq VccQ + 0.3 V. If the A/D and D/A converters are not used, do not leave the AVcc and AVss pins open. Connect AVcc to VccQ, and connect AVss to VssQ.

Current dissipation values shown are for $V_{IH}min = VccQ - 0.5 V$ and $V_{IL}max = 0.5 V$ with all output pins unloaded.

The same voltage should be supplied to Vcc, Vcc-RTC, Vcc-PLL1, and Vcc-PLL2.

* If the IRL and IRLS interrupts are used, the minimum is 1.9 V.

RENESAS

Table 24.3 Permissible Output Current Values

 $VccQ = 3.3 \pm 0.3 V$, Vcc = 1.55 V to 2.15 V, $AVcc = 3.3 \pm 0.3 V$, Ta = -20 to $75^{\circ}C$

| Bus buffer-on time 1 | t _{BON1} | 0 | 15 | ns | |
| Bus buffer-on time 2 | t _{BON2} | 0 | 15 | ns | |

Notes: 1. RESETP, NMI, and IRQ5 to IRQ0 are asynchronous. Changes are detected at the clock fall when the setup time shown is used. If the setup time cannot be used, detection can be delayed until the next clock falls.

- 2. $t_{RESPW} = t_{OSC1} (100 \ \mu s)$ when XTAL oscillation is continued in standby mode, and $t_{RESPW} = t_{OSC2} (10 \ m s)$ when oscillation is stopped. In sleep mode, $t_{RESPW} = t_{PLL1} (100 \ \mu s)$. When the clock multiplication ratio is changed, $t_{RESPW} = t_{PLL1} (100 \ \mu s)$.
- 3. In standby mode, $t_{RESMW} = t_{OSC2}$ (10 ms). In sleep mode, RESETM must be kept low until STATUS (0-1) changes to reset (HH). When the clock multiplication ratio is changed, RESETM must be kept low until STATUS (0-1) changes to reset (HH).

24.3.10 AC Characteristic Test Conditions

I/O signal reference level: VccQ/2 ($VccQ = 3.3 \pm 0.3$ V, Vcc = 1.55 V to 2.15 V)

Input pulse level: Vss to 3.0 V (where RESETP, RESETM, ASEMDO, IRL3 to IRL0, IRLS3 to IRLS0, ADTRG, PINT15 to PINT0, TRST, RxD1, CA, NMI, IRQ5–IRQ0, CKIO, and MD5–MD0 are within Vss to Vcc)

Input rise and fall times: 1 ns

Figure 24.59 Output Load Circuit

www.DataSheet4U.com Rev. 5.0, 09/03, page 755 of 806

24.3.11 Delay Time Variation Due to Load Capacitance

A graph (reference data) of the variation in delay time when a load capacitance greater than that stipulated (30 pF) is connected to the SH7729R's pins is shown below. The graph shown in figure 24.60 should be taken into consideration in the design process if the stipulated capacitance is exceeded in connecting an external device.

www.DataSheet4U.com

If the connected load capacitance exceeds the range shown in figure 24.60, the graph will not be a straight line.

Figure 24.60 Load Capacitance vs. Delay Time

24.4 A/D Converter Characteristics

Table 24.10 lists the A/D converter characteristics.

Table 24.10 A/D Converter Characteristics

 $VccQ = 3.3 \pm 0.3 V$, Vcc = 1.55 V to 2.15 V, $AVcc = 3.3 \pm 0.3 V$, Ta = -20 to 75°C

| Item | Min | Тур | Max | Unit |
|---|-----|-----|------|------|
| Resolution | 10 | 10 | 10 | bits |
| Conversion time | 15 | — | _ | μs |
| Analog input capacitance | — | — | 20 | pF |
| Permissible signal-source (single- source) impedance | — | — | 5 | kΩ |
| Nonlinearity error | — | — | ±3 | LSB |
| Offset error | _ | _ | ±2 | LSB |
| Full-scale error | — | — | ±2 | LSB |
| Quantization error | — | — | ±0.5 | LSB |
| Absolute accuracy | _ | _ | ±4 | LSB |

24.5 D/A Converter Characteristics

Table 24.11 lists the D/A converter characteristics.

Table 24.11 D/A Converter Characteristics

 $VccQ = 3.3 \pm 0.3 V$, Vcc = 1.55 V to 2.15 V, $AVcc = 3.3 \pm 0.3 V$, Ta = -20 to $75^{\circ}C$

| Item | Min | Тур | Max | Unit | Test Conditions |

- I: Input www.DataSheet4U.com
- O: Output
- H: High-level output
- L: Low-level output
- Z: High impedance
- P: Input or output depending on register setting
- K: Input pin is high impedance, output pin holds its state
- V: I/O buffer off, pull-up MOS on
- Notes: 1. Depending on the clock mode (MD2–MD0 setting).
 - 2. K or P when the port function is used.
 - 3. K or P when the port function is used. Z or O when the port function is not used depending on register setting.
 - 4. K or P when the port function is used. I or O when the port function is not used depending on register setting.
 - 5. Depending on register setting.
 - 6. I or O when the port function is used.
 - 7. Input Schmitt buffers of IRQ[5:0] and ADTRG on; other input buffers off.
 - 8. I when the port function is used. I or O when the port function is not used, depending on register setting.
 - 9. In standby mode, Z or L depending on register setting.
 - 10. In standby mode, Z or H depending on register setting.
 - 11. O when DA output is enabled; Z otherwise.
 - 12. In a power-on reset, leave open or input a high level.

A.2 Pin Specifications

Table A.2 shows the pin specifications.

| V _{cc} Q | 21, 35, 47, 59, 71, 85, 97, 111, 163, 183 | H4, M1, R1, U3, V8, U15, R19, C17, A10, U12 | Power supply | Power supply (3.3 V) |
| V _{CC} -RTC | 3 | E2 | Power supply | RTC oscillator power supply (2.0/1.9/1.8/1.7 V) |
| V _{CC} –PLL1 V _{CC} –PLL2 | 145 150 | F16, E17 | Power supply | PLL power supply (2.0/1.9/1.8/1.7 V) |
| AV _{CC} | 205 | A4 | Power supply | Analog power supply (3.3 V) |
| V _{SS} Q | 19, 33, 45, 57, 69, 83, 95, 109, 161, 181 | H2, M3, R3, T7, U4, W11, W14, T19, C16, C10 | Power supply | Power supply (0 V) |
| V _{cc} | 29, 81, 134, 154, 175 | L3, L4, U11, T11, J17, J16, E18, C19, C12, D12 | Power supply | Internal power supply (2.0/1.9/1.8/1.7 V) |
| V _{SS} | 27, 79, 132, 152, 153, 173 | K3, K4, U10, T10, K17, K16, E19, D17, D19, A12, D13 | Power supply | Internal power supply (0 V) |
| V _{SS} –RTC | 6 | E1 | Power supply | RTC-oscillator power supply (0 V) |
| V _{SS} –PLL1 | 147 | F18 | Power | PLL power supply (0 V) |
| V _{SS} –PLL2 | 148 | F19 | supply | |
| AV _{SS} | 198, 208 | B6, B4 | Power supply | Analog power supply (0 V) |

Note: Except in hardware standby mode, power must be supplied constantly to all power supply pins. In hardware standby mode, power must be supplied to Vcc-RTC and Vss-RTC at least.

A.3 Treatment of Unused Pins

- When RTC is not used
 - EXTAL2: Pull up to V_{CC} (2.0/1.9/1.8/1.7 V)
 - XTAL2: Leave unconnected
 - V_{CC}-RTC: Power supply (2.0/1.9/1.8/1.7 V)
 - V_{SS} -RTC: Power supply (0 V)
- When PLL2 is not used
 - CAP2: Leave unconnected
 - V_{CC}–PLL2: Power supply (2.0/1.9/1.8/1.7 V)
 - ---- V_{SS}-PLL2: Power supply (0 V)
- When on-chip crystal oscillator is not used
 - XTAL: Leave unconnected
- When EXTAL pin is not used
 - EXTAL: Pull up to $V_{CC}Q$ (3.3 V)
- When A/D converter is not used
 - AN[7:0]: Leave unconnected
 - AV_{CC} : Power supply (3.3 V)
 - AV_{SS} : Power supply (0 V)
- When UDI is not used
 - ASEMD0: Pull up to $V_{CC}Q$ (3.3 V)
- When hardware standby mode is not used
 - CA: Pull up (3.3 V)

Notes: 1. Modules:

UBC: User break controller

CPG: Clock pulse generatorBSC: Bus state controllerRTC: Realtime clockINTC: Interrupt controllerTMU: Timer unitSCI: Serial communication interface

2. Internal buses:

CCN: Cache controller

- L: CPU, CCN, cache, TLB, and DSP connected
- I: BSC, cache, DMAC, INTC, CPG, and UDI connected
- P: BSC and peripheral modules (RTC, TMU, SCI, SCIF, IrDA, A/D, D/A, DMAC, ports, CMT) connected
- 3. The access size shown is for control register access (read/write). An incorrect result will be obtained if a different size from that shown is used for access.
- 4. To exclude area 1 control registers from address translation by the MMU, set the first 3 bits of the logical address to 101, to locate the registers in the P2 space.
- 5. With 16-bit access, it is not possible to read data in two registers simultaneously.
- 6. With 32-bit access, it is possible to read data in the register at [accessed address + 2] simultaneously.
