## DUAL RETRIGGERABLE MONOSTABLE MULTIVIBRATOR

- HIGH SPEED
  - $t_{PD} = 25 \text{ ns} (TYP) \text{ at } V_{CC} = 5V$
- LOW POWER DISSIPATION

  STANDBY STATE I<sub>CC</sub>=4 μA (MAX.) AT T<sub>A</sub>=25°C

  ACTIVE STATE I<sub>CC</sub> = 700 μA (MAX.) AT V<sub>CC</sub>=5V
- HIGH NOISE IMMUNITY V<sub>NIH</sub> = V<sub>NIL</sub> = 28 % V<sub>CC</sub> (MIN.)
- OUTPUT DRIVE CAPABILITY 10 LSTTL LOADS
- SYMMETRICAL OUTPUT IMPEDANCE IOH = IOL = 4 mA (MIN.)
- BALANCED PROPAGATION DELAYS tplh = tphl
- WIDE OPERATING VOLTAGE RANGE Vcc (OPR) = 2 V TO 6 V
- WIDE OUTPUT PULSE WIDTH RANGE twout = 120 ns ~ 60 s OVER AT V<sub>CC</sub> = 4.5 V
- PIN AND FUNCTION COMPATIBLE WITH 54/74LS423

#### **DESCRIPTION**

The M54/74HC423/423A are high speed CMOS MONOSTABLE multivibrators fabricated with silicon gate C<sup>2</sup>MOS technology.

They achieve the high speed operation similar to equivalent LSTTL while maintaining the CMOS low power dissipation. There are two trigger inputs,  $\overline{A}$  INPUT (negative edge) and B INPUT (positive edge). These inputs are valid for rising/falling signals, ( $t_r - t_f - 1$  sec). After triggering the output maintains the MONOSTABLE state for the time period determined by the external resistor Rx and capacitor Cx.

Two different pulse width constant are available:  $K \cong 0.46$  for HC423  $K \cong 1$  for HC423A.

Taking CLR low breaks this MONOSTABLE STATE. If the next trigger pulse occurs during the MONOSTABLE period it makes the MONOSTABLE period longer. Limit for values of Cx and Rx:

Cx: NO LIMIT

Rx :  $V_{CC}$  < 3.0 V 5 K  $\Omega$  to 1 M  $\Omega$ V<sub>CC</sub>  $\geq$  3.0 V 1 K  $\Omega$  to 1 M  $\Omega$ 

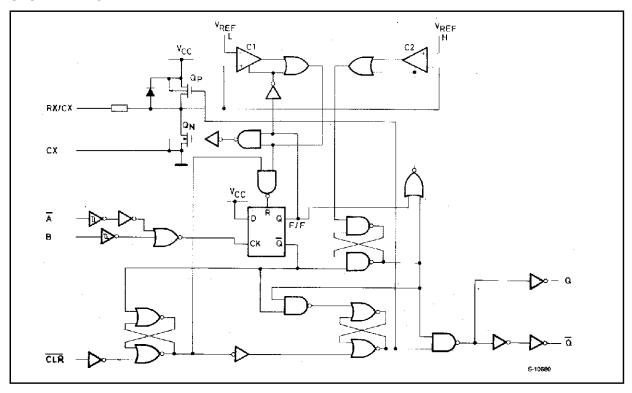

All inputs are equipped with protection circuits against static discharge and transient excess voltage.

October 1993 1/14

## **SYSTEM DIAGRAM**

## **TIMING CHART**

#### **BLOCK DIAGRAM**

#### Note:

- (1) Cx, Rx, Dx are external components.
- (2) Dx is a clamping diode.

The external capacitor is charged to  $V_{CC}$  in the stand-by state, i.e. no trigger. When the supply voltage is turned off Cx is discharged mainly through an internal parasitic diode (see figures). If Cx is sufficiently large and  $V_{CC}$  decreases rapidy, there will be some possibility of damaging the I.C. with a surge current or latch-up. If the voltage supply filter capacitor is large enough and  $V_{CC}$  decrease slowly, the surge current is automatically limited and damage the I.C. is avoided. The maximum forward current of the parasitic diode is approximately 20 mA. In cases where Cx is large the time taken for the supply voltage to fall to 0.4  $V_{CC}$  can be calculated as follows:

 $t_f \ge (V_{CC} - 0.7) \cdot Cx/20mA$ 

In cases where t<sub>i</sub> is too short an external clamping diode is required to protect the I.C. from the surge current.

#### **FUNCTIONAL DESCRIPTION**

#### STAND-BY STATE

The external capacitor, Cx, is fully charged to Vcc in the stand-by state. Hence, before triggering, transistor Qp and Qn (connected to the Rx/Cx node) are both turned-off. The two comparators that control the timing and the two reference voltage sources stop operating. The total supply current is therefore only leakage current.

#### TRIGGER OPERATION

Triggering occurs when:

1 st) A is "low" and B has a falling edge;

2 nd) B is "high" and A has a rising edge;

3 rd) A is low and B is high and C1 has a rising edge.

After the multivibrator has been retriggered comparator C1 and C2 start operating and Qn is turned on. Cx then discharges through Qn. The voltage at the node R/C external falls.

When it reaches V<sub>REFL</sub> the output of comparator C1 becomes low. This in turn resets the flip-flop and Qn is turned off.

At this point C1 stops functioning but C2 continues to operate.

The voltage at R/C external begins to rise with a time constant set by the external components Rx, Cx.

Triggering the multivibrator causes Q to go high after internal delay due to the flip-flop and the gate. Q remains high until the voltage at R/C external rises again to V<sub>REFH</sub>. At this point C2 output goes low and O goes low. C2 stop operating. That means that after triggering when the voltage R/C external returns to V<sub>REFH</sub> the multivibrator has returned to its MONOSTABLE STATE. In the case where Rx  $\cdot$  Cx are large enough and the discharge time of the capacitor and the delay time in the I.C. can be ignored, the width of the output pulse tw (out) is as follows :

 $t_{W(OUT)} = 0.46 \text{ Cx} \cdot \text{Rx} \text{ (HC423)}$  $t_{W(OUT)} = \text{Cx} \cdot \text{Rx} \text{ (HC423A)}$ 

#### **FUNCTIONAL DESCRIPTION (continued)**

#### **RE-TRIGGERED OPERATION**

When a second trigger pulse follows the first its effect will depend on the state of the multivibrator. If the capacitor Cx is being charged the voltage level of R/C external falls to Vrefl again and Q remains high i.e. the retrigger pulse arrives in a time shorter than the period Rx · Cx seconds, the capacitor charging time constant. If the second trigger pulse is very close to the initial trigger pulse it is ineffective; i.e. the second trigger must arrive in the capacitor discharge cycle to be ineffective; Hence the

minimum time for a second trigger to be effective depends on  $V_{CC}$  and Cx.

#### **RESET OPERATION**

CL is normally high. If CL is low, the trigger is not effective because Q output goes low and trigger control flip-flop is reset.

Also transistor Op is turned on and Cx is charged quicky to  $V_{CC}$ . This means if CL input goes low, the IC becomes waiting state both in operating and non operating state.

#### **TRUTH TABLE**

|   | INPUTS |    |          | PUTS | NOTE          |

<sup>(\*)</sup> C<sub>PD</sub> is defined as the value of the IC's internal equivalent capacitance which is calculated from the operating current consumption without load. (Refer to Test Circuit). Average operting current can be obtained by the following equation.  $I_{CC}(opr) = C_{PD} \bullet V_{CC} \bullet f_{IN} + I_{CC}$ : Duty/100 + I<sub>C</sub>/2 (per monostable) (I<sub>CC</sub>: Active Supply Current) (Duty:%)
