

## Multi-Mode Serial Transceiver

- Single-Chip Serial Transceiver Supports Industry-Standard
- Software-Selectable Protocols:
  - RS-232 (V.28)
  - RS-422A (V.11, X.27)
  - RS-449
  - RS-485
  - V.35
  - EIA-530
- Programmable Selection of Interface
- +5V-Only Operation
- Six (6) Drivers and Seven (7) Receivers
- Surface Mount Packaging

### DESCRIPTION...

The **SP502** is a highly integrated serial transceiver that allows software control of its interface modes. It offers hardware interface modes for RS-232 (V.28), RS-422A (V.11), RS-449, RS-485, V.35, and EIA-530. The **SP502** is fabricated using low-power BiCMOS process technology, and incorporates a **Sipex** patented (5,306,954) charge pump allowing +5V only operation.

# SPECIFICATIONS

## PINOUT...

## PIN ASSIGNMENTS...

### CLOCK AND DATA GROUP

Pin 1 — RxD — Receive Data; TTL output, sourced from RD(a) and RD(b) inputs.  
 Pin 14 — TxD — TTL input ; transmit data source for SD(a) and SD(b) outputs.  
 Pin 15 — TxC — Transmit Clock; common TTL input for both ST and TT driver outputs.  
 Pin 20 — RxC — Receive Clock; TTL output sourced from RT(a) and RT(b) inputs.  
 Pin 37 — RT(a) — Receive Timing; analog input, inverted; source for RxC.  
 Pin 38 — RT(b) — Receive Timing; analog input, non-inverted; source for RxC.  
 Pin 42 — ST(a) — Send Timing; analog output, inverted; sourced from ST.  
 Pin 44 — ST(b) — Send Timing; analog output, non-inverted; sourced from ST.  
 Pin 59 — SD(b) — Analog Out — Send data, non-inverted; sourced from TxD.  
 Pin 61 — SD(a) — Analog Out — Send data, inverted; sourced from TxD.  
 Pin 63 — TT(a) — Analog In or Out — Terminal Timing, inverted; sourced to TxC or RxT.  
 Pin 65 — TT(b) — Analog In or Out — Terminal Timing, non-inverted; sourced to TxC or RxT.

Pin 70 — RD(a) — Receive Data, analog input; inverted; source for RxD.

Pin 71 — RD(b) — Receive Data; analog input; non-inverted; source for RxD.

### CONTROL LINE GROUP

Pin 13 — DTR — Data Terminal Ready; TTL input; source for TR(a) and TR(b) outputs.

Pin 16 — RTS — Ready To Send; TTL input; source for RS(a) and RS(b) outputs.

Pin 17 — RL — Remote Loopback; TTL input; source for RL(a) and RL(b) outputs.

Pin 19 — DCD — Data Carrier Detect; TTL output; sourced from RR(a) and RR(b) inputs.

Pin 21 — RI — Ring In; TTL output; sourced from IC(a) and IC(b) inputs.

Pin 24 — LL — Local Loopback; TTL input; source for LL(a) and LL(b) outputs.

Pin 35 — RR(a) — Receiver Ready; analog input, inverted; source for DCD.

Pin 36 — RR(b) — Receiver Ready; analog input, non-inverted; source for DCD.

Pin 39 — IC(a) — Incoming Call; analog input, inverted; source for RI.

Pin 40 — IC(b) — Incoming Call; analog input, non-inverted; source for RI.

Pin 45 — RL(b) — Remote Loopback; analog output, non-inverted; sourced from RL.

Pin 47 — RL(a) — Remote Loopback; analog output inverted; sourced from RL.

Pin 49 — LL(b) — Local Loopback; analog output, non-inverted; sourced from LL.

Pin 51 — LL(a) — Local Loopback; analog output, inverted; sourced from LL.

Pin 52 — RS(b) — Ready To Send; analog output, non-inverted; sourced from RTS.

Pin 54 — RS(a) — Ready To Send; analog output, inverted; sourced from RTS.

Pin 56 — TR(b) — Terminal Ready; analog output, non-inverted; sourced from DTR.

Pin 58 — TR(a) — Terminal Ready; analog output, inverted; sourced from DTR.

Pin 66 — CS(a) — Clear To Send; analog input, inverted; source for CTS.

Pin 67 — CS(b) — Clear To Send; analog input, non-inverted; source for CTS.

Pin 68 — DM(a) — Data Mode; analog input, inverted; source for DSR.

Pin 69 — DM(b) — Data Mode; analog input, non-inverted; source for DSR.

Pin 78 — DSR— Data Set Ready; TTL output; sourced from DM(a), DM(b) inputs.

Pin 80 — CTS— Clear To Send; TTL output; sourced from CS(a) and CS(b) inputs.

## CONTROL REGISTERS

Pins 2–5 — RDEC0 – RDEC3 — Receiver decode register; configures receiver modes; TTL inputs.

Pin 6 — ST/TT — Enables ST or TT drivers, TTL input.

Pins 12–9 — TDEC0 – TDEC3 — Transmitter decode register; configures transmitter modes; TTL inputs.

## POWER SUPPLIES

Pins 8, 25, 33, 41, 48, 55, 62, 73, 74 —  $V_{CC}$  — +5V input.

Pins 7, 29, 34, 43, 46, 50, 53, 57, 60, 64, 72, 75 — GND — Ground.

Pin 27 —  $V_{DD}$  +10V Charge Pump Capacitor — Connects from  $V_{DD}$  to  $V_{CC}$ . Suggested capacitor size is 22 $\mu$ F, 16V.

Pin 32 —  $V_{SS}$  –10V Charge Pump Capacitor — Connects from ground to  $V_{SS}$ . Suggested capacitor size is 22 $\mu$ F, 16V.

Pins 26 and 30 —  $C_1^+$  and  $C_1^-$  — Charge Pump Capacitor — Connects from  $C_1^+$  to  $C_1^-$ . Suggested capacitor size is 22 $\mu$ F, 16V.

Pins 28 and 31 —  $C_2^+$  and  $C_2^-$  — Charge Pump Capacitor — Connects from  $C_2^+$  to  $C_2^-$ . Suggested capacitor size is 22 $\mu$ F, 16V.

NOTE: NC pins should be left floating; internal signals may be present.

## FEATURES...

The **SP502** is a highly integrated serial transceiver that allows software control of its interface modes. The **SP502** offers hardware interface modes for RS-232 (V.28), RS-422A (V.11), RS-449, RS-485, V.35, and EIA-530. The interface mode selection is done via an 8-bit switch; four (4) bits control the drivers and four (4) bits control the receivers. The **SP502** is fabricated using low-power BiCMOS process technology, and incorporates a **Sipex** patented (5,306,954) charge pump allowing +5V only operation. Each

device is packaged in an 80-pin Quad FlatPack package.

The **SP502** is ideally suited for wide area network connectivity based on the interface modes offered and the driver and receiver configurations. The **SP502** has five (5) independent drivers and six (6) independent receivers and one half-duplex transceiver channel, which allows a maximum of six (6) drivers and seven (7) receivers. The driver and receiver configuration for the **SP502** is ideal for DTE applications. The **SP502** is made up of four separate circuit blocks – the charge pump, drivers, receivers, and decoder. Each of these circuit blocks is described in detail below.

## THEORY OF OPERATION

### Charge-Pump

The charge pump is a **Sipex** patented design (5,306,954) and uses a unique approach compared to older less efficient designs. The charge pump still requires four external capacitors, but uses a four-phase voltage shifting technique to attain symmetrical 10V power supplies. *Figure 3a* shows the waveform found on the positive side of capacitor  $C_2$ , and *Figure 3b* shows the negative side of capacitor  $C_2$ . There is a free-running oscillator that controls the four phases of the voltage shifting. A description of each phase follows.

### Phase 1

—  $V_{SS}$  charge storage — During this phase of the clock cycle, the positive side of capacitors  $C_1$  and  $C_2$  are initially charged to +5V.  $C_1^+$  is then switched to ground and the charge on  $C_1^-$  is transferred to  $C_2^-$ . Since  $C_2^+$  is connected to +5V, the voltage potential across capacitor  $C_2$  is now 10V.

### Phase 2

—  $V_{SS}$  transfer — Phase two of the clock connects the negative terminal of  $C_2$  to the  $V_{SS}$  storage capacitor and the positive terminal of  $C_2$  to ground, and transfers the generated –10V to  $C_3$ . Simultaneously, the positive side of capaci-

**Figure 1. Charge Pump Phase 1.**

for  $C_1$  is switched to +5V and the negative side is connected to ground.

### Phase 3

—  $V_{DD}$  charge storage — The third phase of the clock is identical to the first phase — the charge transferred in  $C_1$  produces -5V in the negative terminal of  $C_1$ , which is applied to the negative side of capacitor  $C_2$ . Since  $C_2^+$  is at +5V, the voltage potential across  $C_2$  is 10V.

### Phase 4

—  $V_{DD}$  transfer — The fourth phase of the clock connects the negative terminal of  $C_2$  to ground and transfers the generated 10V across  $C_2$  to  $C_4$ , the  $V_{DD}$  storage capacitor. Again, simultaneously with this, the positive side of capacitor  $C_1$  is switched to +5V and the negative side is connected to ground, and the cycle begins again.

Since both  $V^+$  and  $V^-$  are separately generated from  $V_{CC}$  in a no-load condition,  $V^+$  and  $V^-$  will be symmetrical. Older charge pump ap-

**Figure 2. Charge Pump Phase 2.**

proaches that generate  $V^-$  from  $V^+$  will show a decrease in the magnitude of  $V^-$  compared to  $V^+$  due to the inherent inefficiencies in the design.

The clock rate for the charge pump typically operates at 15kHz. The external capacitors must be 22 $\mu$ F with a 16V breakdown rating. Two external Schottky diodes connected as in *Figure 6* are required for high rate of rise power supplies.

### External Power Supplies

For applications that do not require +5V only, external supplies can be applied at the  $V^+$  and  $V^-$  pins. The value of the external supply voltages must be no greater than  $\pm 10V$ . The current drain for the  $\pm 10V$  supplies is used for RS-232, and RS-423 drivers. For the RS-232 driver the current requirement will be 3.5mA per driver, and for the RS-423 driver the worst case current drain will be 11mA per driver. The external

**Figure 3. Charge Pump Waveforms**

Figure 4. Charge Pump Phase 3.

Figure 5. Charge Pump Phase 4.

power supplies should provide a power supply sequence of: +10V, then +5V, followed by -10V.

## Drivers

The **SP502** has six (6) drivers which can be programmed in six different modes of operation. One of the drivers for the **SP502** is internally connected to an internal receiver input to make up a half-duplex configuration. As shown in the Mode Diagrams, the driver input of the half-duplex channel is shared with an adjacent driver such that when one is active the other is disabled.

Control for the mode selection is done via a four-bit control word. The **SP502** does not have a latch; the control word must be externally latched either high or low to write the appropriate code into the **SP502**. The drivers are pre-

arranged such that for each mode of operation the relative position and functionality of the drivers are set up to accommodate the selected interface mode. As the mode of the drivers is changed, the electrical characteristics will change to support the requirements of clock, data, and control line signal levels. *Table 1* shows a summary of the electrical characteristics of the drivers in the different interface modes. Unused driver inputs can be left floating; however, to ensure a desired state with no input signal, pull-up resistors to +5V or pull-down resistors to ground are suggested. Since the driver inputs are both TTL or CMOS compatible, any value resistor less than 100kΩ will suffice.

There are three basic types of driver circuits — RS-232, RS-423, and RS-485. The RS-232 drivers output a minimum of ±5V level single-ended signals (with 3kΩ and 2500pF loading), and

\*The ST and TT driver outputs cannot be enabled simultaneously.

Table 1. SP502 Drivers

can operate up to 120kbps. The RS-232 drivers are used in RS-232 mode for all signals, and also in V.35 mode where they are used as the control line signals.

The RS-423 drivers output a minimum of  $\pm 3.6V$  level single-ended signals (with  $450\Omega$  loading) and can operate up to 120kbps. Open circuit  $V_{OL}$  and  $V_{OH}$  measurements may exceed the  $\pm 6V$  limitation of RS-423. The RS-423 drivers are used in RS-449 and EIA-530 modes as RL and LL outputs.

The third type of driver supports RS-485, which is a differential signal that can maintain  $\pm 1.5V$  differential output levels with a worst case load of  $54\Omega$ . The signal levels and drive capability of the RS-485 drivers allow the drivers to also support RS-422 requirements of  $\pm 2V$  differential output levels with  $100\Omega$  loads. The RS-422 drivers are used in RS-449 and EIA-530 modes as clock, data, and some control line signals.

The RS-485-type drivers are also used in the V.35 mode. V.35 levels require  $\pm 0.55V$  signals with a load of  $100\Omega$ . In order to meet the voltage requirements of V.35, external series resistors with source impedance termination resistors must be implemented to voltage divide the driver outputs from 0 to +5V to 0 to +0.55V. *Figure 6* shows the values of the resistor network and how to connect them. The termination network also achieves the  $50\Omega$  to  $150\Omega$  source imped-

ance for V.35. For applications that require V.11 signals for clock and data instead of V.35 levels, omit the external termination networks. All of the differential drivers, RS-485, RS-422, and V.35 can operate up to 5Mbps.

## Receivers

The **SP502** is equipped with seven (7) receivers which can be programmed in six (6) different modes of operation. One of the seven (7) receivers (RxT) is part of a half-duplex channel, which means its inputs are shared with a driver output, as shown in the Mode Diagrams. The RxT receiver has its inputs internally connected to the TT(a) and TT(b) pins. The select pin labeled ST/TT enables either the TT-driver or the ST-driver, but it does not disable the receiver. The RxT receiver is always connected to the TT(a) and TT(b) pins. Any signal that is received or transmitted on TT(a) and TT(b) will trigger a TTL-output at the RxT pin.

Control for the mode selection is done via a 4-bit control word that is independent from the driver control word. The coding for the drivers and receivers is identical. Therefore, if the modes for the drivers and receivers are supposed to be identical in the application, the control lines can be tied together.

Like the drivers, the receivers are pre-arranged for the specific requirements of the interface. As the operating mode of the receivers is changed,

| Pin Label                            | Mode:     | RS-232              | V.35                | RS-422  | RS-485  | RS-449              | EIA-530             |

\*TT(a) and TT(b) can be programmed as driver outputs or receiver inputs.

**Table 2. SP502 Receivers**

the electrical characteristics will change to support the requirements of clock, data, and control line receivers. *Table 2* shows a summary of the electrical characteristics of the receivers in the different interface modes. Unused receiver inputs can be left floating without causing oscillation. To ensure a desired state of the receiver output, a pull-up resistor of 100k $\Omega$  to +5V should be connected to the inverting input for a logic LOW, or the non-inverting input for a logic high. For single-ended receivers, a pull-down resistor to ground of 5k $\Omega$  is internally connected, which will ensure a logic HIGH output.

There are three basic types of receivers — RS-232, RS-423, and RS-485. The RS-232 receiver is a single-ended input with a threshold of 0.8V to 2.4V. The RS-232 receiver has an operating voltage range of  $\pm 15$ V and can receive signals up to 120kbps. RS-232 receivers are used in RS-232 mode for all signal types, and in V.35 mode for control line signals.

The RS-423 receivers are also single-ended but have an input threshold as low as  $\pm 200$ mV. The input impedance is guaranteed to be greater than 4k $\Omega$ , with an operating voltage range of  $\pm 7$ V. The RS-423 receivers can operate up to 120kbps. RS-423 receivers are used for the IC signal in RS-449 and EIA-530 modes, as shown in *Table 2*.

The third type of receiver supports RS-485, which is a differential interface mode. The RS-485 receiver has an input impedance of 15k $\Omega$  and a differential threshold of  $\pm 200$ mV.

Since the characteristics of an RS-422 receiver are actually subsets of RS-485, the receivers for RS-422 requirements are identical to the RS-485 receivers. RS-422 receivers are used in RS-449 and EIA-530 for receiving clock, data, and some control line signals. The RS-485 receivers are also used for the V.35 mode. V.35 levels require the  $\pm 0.55$ V signals with a load of 100 $\Omega$ . In order to meet the V.35 input impedance of 100 $\Omega$ , the external termination network of *Figure 6* must be applied. The threshold of the V.35 receiver is  $\pm 200$ mV. The V.35 receivers can operate up to 5Mbps. All of the differential receivers can receive data up to 5Mbps.

## Decoder

The **SP502** has the ability to change the interface mode of the drivers or receivers via an 8-bit switch. The decoder for the drivers and receivers is not latched; it is merely a combinational logic switch. The codes shown in *Tables 1 and 2* are the only specified, valid modes for the **SP502**. Undefined codes may represent other interface modes not specified or random outputs (consult the factory for more information). The drivers are controlled with the data bits labeled TDEC<sub>3</sub>–TDEC<sub>0</sub>. The drivers can be put into tri-state mode by writing 0000 to the driver decode switch. The receivers are controlled with data bits RDEC<sub>3</sub>–RDEC<sub>0</sub>; the code 0000 written to the receivers will place the outputs in an undetermined state. All receivers, with the exception of SCT, do not have tri-state capability; the outputs will either be HIGH or LOW depending upon the state of the receiver input.

| MODE: RS-232      |                   |                   |                   |                   |                   |                   |                   |
|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|

Figure 12. Mode Diagram — EIA-530

## APPLICATION EXAMPLE

The example application that follows is a fully configured serial I/O channel in a DTE configuration. The example is comprised of the following functional elements:

- Processor
- SCC
- **SP502**
- Mode Select Register (R0[WR])
- RL & LL Control Bit Register (R1[WR])
- RI Status Bit Register (R1[RD])
- Address Decode Logic
- Baud Rate Clock Source
- I/O Connector Interface

Each of the elements of the application example are described below. Please refer to *Figure13*.

### Processor

The example schematic shows a generic 8-bit processor connected to a generic SCC. The processor is also connected to three registers. The registers are described in further detail below.

### Address Decode Logic

The address decode logic is connected to the Processor control and address busses and provides the logic necessary to decode the I/O read and write operations for the SCC, Mode Select Register, RL and LL Control Bit Register and the RI Status Bit Register.

### SCC

The SCC provides the I/O functions for a single serial channel. The SCC is connected to the Processor I/O bus and is programmed by the user software. The SCC's TTL-level serial I/O pins are connected to the corresponding TTL-level serial I/O pins on the **SP502**.

### SP502

The **SP502** provides buffering and translation from TTL levels to the selected physical level interface standard, such as RS-232, V.35, etc. The physical level interface pins are connected to a standard 25 pin D-subminiature connector wired in a DTE configuration with the pin assignments corresponding to the EIA-530 specification. This choice was purely arbitrary. However, it provides all the necessary signals to

support standards other than EIA-530, such as V.35, RS-232, RS-449, etc. with an appropriate cable adapter.

The **SP502** driver and receiver modes are independently configured by programming the **SP502**'s RDEC and TDEC input pins. In the example, the pins are driven by the Mode Select Register with a programmed value stored by the user's software.

Since the **SP502** is shown in a DTE configuration, the example assumes that any synchronous interface clocking will be provided by the attached DCE device. Consequently, the ST/TT pin is tied to +5V, thus causing the **SP502** to receive the transmit clock on the TT(a) and TT(b) input pins and output the transmit clock to the SCC on the RxT output pin. The receive clock is input to the **SP502** on the RT(a) and RT(b) pins and output to the SCC on the RxC pin.

### Mode Select Register

The mode select register is an 8-bit latch attached to the Processor data bus. The Processor, under user-software control, can program the Mode Select Register with the appropriate values to select the **SP502**'s driver and receiver modes.

The table shown on the schematic below the register lists the values for programming the register to drive the RDEC and TDEC pins on the **SP502** for the desired physical level interface. The receivers and drivers can be programmed independently, but in this example the Mode Select Register must be programmed with both the RDEC and TDEC values at the same time. This is because the RDEC and TDEC pins are driven from the same 8-bit latch.

Note that selecting modes for TDEC that are shown in the table as undefined will result in the drivers operating in an undefined mode and should not be used. Likewise, selecting modes for RDEC that are shown in the table as undefined will result in indeterminate logic levels present on the TTL outputs of the **SP502**. Undefined RDEC or TDEC values should never be programmed.

Several other approaches for driving the RDEC and TDEC signals are possible. One approach would use two independent 4-bit latches, one each to drive the RDEC and TDEC pins as separate groups. Another approach would use one 4-bit latch, each output of the latch would drive a corresponding pair of RDEC/TDEC signals. For instance, RDEC<sub>0</sub> and TDEC<sub>0</sub> could be tied together and be driven by the low order bit of the 4-bit latch.

### RL & LL Control Bit Registers

A 2-bit latch is used to allow the Processor to program the states of the RL and LL interface signals. This latch is necessary since most SCCs do not support RL and LL control signals.

### RI Status Bit Register

A 1-bit read register is implemented using a tri-state buffer. This will allow the Processor to read the state of the **RI** (Ring Indicator) interface signal. This is necessary since most SCCs do not support the **RI** interface signal.

The example interface shows the **SP502A**'s IC(a) input tied to the EIA-530 signal TM (Test Mode). EIA530 does not specify an **RI** signal. If EIA-530 operation is required, the **RI** Status Bit Register could be used to monitor the condition of the TM signal or it could be ignored. For other interface standards, the connector pin 25 on the schematic could be tied to the **RI** signal through a cable adapter arrangement. For instance, if RS-232 operation is used, pin 25 of the connector could be tied to pin 22 of the RS-232 adapter (circuit CE) and the **RI** Status Bit Register then used to monitor the RS-232 signal for ring indicator.

### Baud Rate Clock Source

Most SCCs require an external clock source for operation in asynchronous and self-clocking applications.

### I/O Connector Interface

The I/O connector is wired to the **SP502A** such that the interface represents a DTE device. As shown, the connector is wired in an EIA-530 configuration with EIA-530 signal mnemonics. A 25-pin connector wired to the EIA-530 specification provides pins for all interface signals supported by the **SP502**. If the **SP502** is programmed for other physical interfaces, such as V.35, then an adapter cable will provide the necessary conversion from the EIA-530 pin-outs to those required by the V.35 standard together with its ISO-2593 connector.

### Notes Regarding V.35 Operation

The user will have to provide additional resistor networks if correct V.35 signal levels and termination impedances are required. This is necessary because the **SP502** does not provide V.35 signal terminations when programmed for V.35 operation. Two approaches are possible. First, if the **SP502** is permanently programmed to operate as V.35 only, with no other interface standard required, then the appropriate resistors can be mounted on the PCB near the **SP502**. Second, if the **SP502** will be programmed for a variety of standards, then a better approach might be to provide the resistors as part of the cable adapter assembly used to convert from the standard EIA-530 connector pin-outs shown in the example to the V.35/ISO-2593 connector and pin-outs.

## SP502/SP503 EVALUATION BOARD

The **SP502/SP503 Evaluation Board (EB)** is designed to offer as much flexibility to the user as possible. Each board comes equipped with an 80-pin QFP Zero-Insertion Force socket to allow for testing of multiple devices. The control lines and inputs and outputs of the device can be controlled either manually or via a data bus under software control. There is a 50-pin connector to allow for easy connection to an existing system via ribbon cable. There are also open areas on the PC board to add additional circuitry to support application-specific requirements.

### Manual Control

The **SP502/SP503EB** will support both the **SP502** or **SP503** multi-mode serial transceivers. When used for the **SP502**, disregard all notation on the board that is in [brackets]. The **SP502** has a half-duplex connection between the RxT receiver and the TT driver. Due to this internal connection, the RxT receiver inputs can be accessed via the TT(a) and TT(b) pins. If the user needs separate receiver input test pins, jumpers JP1 and JP2 can be inserted to allow for separate receiver inputs located at SCT(a) and SCT(b). The corresponding TTL output for this receiver is labeled as SCT. This test point is tied to pin 79 of the **SP502** or **SP503**. Pin 7 of the evaluation board is connected to the DIP switch, and is labeled as (SCTEN). When used with the **SP502**, this pin should be switched to a low state. When the evaluation board is used with the **SP503**, pin 7 is a tri-state control pin for the SCT receiver.

The transceiver I/O lines are brought out to test pins arranged in the same configuration as shown elsewhere in this data sheet. A top layer silk-screen shows the drivers and receivers to allow direct correlation to the data sheet. The transmitter and receiver decode bits are tied together and are brought out to a DIP switch for manual control of both the driver and receiver interface modes. Since the coding for the drivers and receivers is identical, the bits have been tied together. The DIP switch has 7 positions, four of which are reserved for the TDEC/RDEC control. The other three are used as tri-state control pins. The labels that are in [brackets] apply only to the **SP503**.

If a logic one is asserted, the corresponding red LED will be lit. If a zero is asserted, the corresponding red LED will not be lit.

### Software Control

A 50-pin connector brings all the analog and digital I/O lines,  $V_{CC}$ , and GND to the edge of the card. This can be wired to the user's existing design via ribbon cable. The pinout for the connector is described in the following section. When the evaluation board is operated under software control, the DIP switch should be set up so that all bits are LOW (all LEDs off). This will tie pull-down resistors from the inputs to ground and let the external system control the state of the control inputs.

### Power and Ground Requirements

The evaluation board layout has been optimized for performance by using basic analog circuit techniques. The four charge-pump capacitors must be  $22\mu\text{F}$  (16V) and be placed as close to the unit as possible; tantalum capacitors are suggested. The decoupling capacitor must be a minimum of  $1\mu\text{F}$ ; depending upon the operating environment,  $10\mu\text{F}$  should be enough for worst case situations. The ground plane for the part must be solid, extending completely under the package. The power supplies for the device should be as accurate as possible; for rated performance  $\pm 5\%$  is necessary. The power supply current will vary depending upon the selected mode, the amount of loading and the data rate. As a maximum, the user should reserve 200mA for  $I_{CC}$ . The worst-case operating mode is RS-485 under full load of six (6) drivers supplying 1.6V to  $54\Omega$  loads. The power and ground inputs can be supplied through either the banana jacks on the evaluation board (Red =  $V_{CC} = +5V \pm 5\%$ ; Black = GND) or through the connector.

For reference, the 80-pin QFP Socket is a TESCO part number FPQ-80-65-09A. The 50-pin connector is an AMP part number 749075-5.
