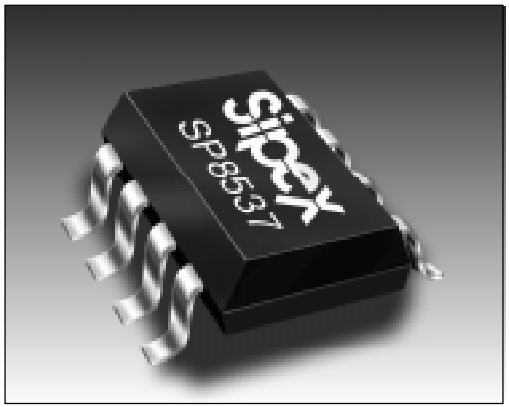
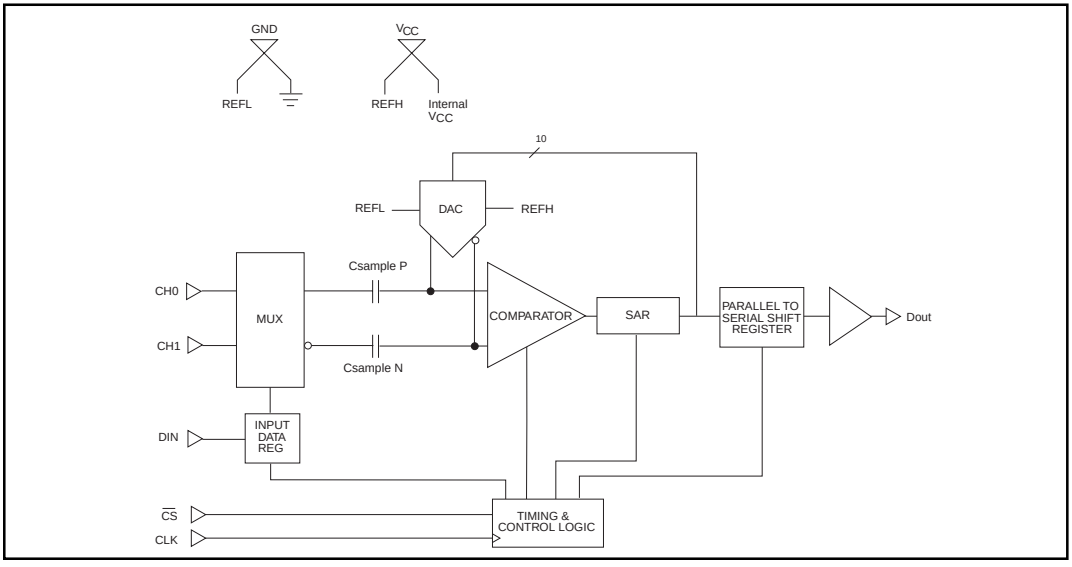
Micropower Sampling 10-Bit A/D Converter

- Low Cost
- 10-Bit Serial Sampling ADC
- 8-Pin NSOIC Plastic Package
- Low Power @ 250µA including Automatic Shutdown: 1nA(typ)
- Programmable Input Configuration: Full differential or 2 channel single-ended
- Single Supply 3.0V to 5.5V operation
- Half Duplex Digital Serial Interface
- Sample Rate: 33.9µS



DESCRIPTION

The **SP8537** is a very low power 10-Bit data acquisition chip. The**SP8537** typically draws 250µA of supply current when sampling at 29.5 kHz. Supply current drops linearly as the sample rate is reduced. The ADC automatically powers down when not performing conversions, drawing only leakage current. The **SP8537** is available in 8-Pin NSOIC packages, specified over Commercial, Industrial and Extended temperature ranges. The **SP8537** is best suited for Battery-Operated Systems, Portable Data Acquisition Instrumentation, Battery Monitoring, and Remote Sensing applications. The serial port allows efficient data transfer to a wide range of microprocessors and microcontrollers over 3 or 4 wires.

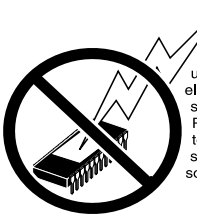


SP8537 Block Diagram

ABSOLUTE MAXIMUM RATINGS

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

(TA=+25˚C unless otherwise noted) .....
VCC to GND 7.0V
Vin to GND ..... -0.3 to VCC +0.3V
Digital input to GND ..... -0.3 to VCC +0.3V
Digital output to GND ..... -0.3 to VCC +0.3V
Operating Temperature Range
Commercial (J, K Version) ..... 0˚C to 70˚C
Industrial (A, B Version) ..... -40˚C to +85˚C
Lead Temperature (Solder 10Sec) ..... +300˚C
Storage Temperature ..... -65˚C to +150˚C
Power Dissipation to 70˚C 500mW



CAUTION:
ESD (ElectroStatic Discharge) sensitive device. Permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. Personnel should be properly grounded prior to handling this device. The protective foam should be discharged to the destination socket before devices are removed.

SPECIFICATIONS

Unless otherwise noted the following specifications apply for VCC=5V or 3.3V with limits applicable for Tmin to Tmax. Typical applies for Ta=25˚C.

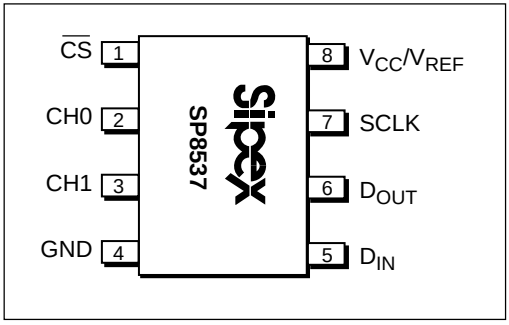
PIN DESCRIPTION



PIN ASSIGNMENTS

Pin 1- $\overline{CS}$ - Chip Select.

Pin 2- CH0 - Channel 0

Pin 3- CH1 - Channel 1

Pin 4- GND - Ground

Pin 5- D_{IN} - Data In

Pin 6 - D_{OUT} - Data Out

Pin 7- SCLK - Serial Clock

Pin 8- V_{CC}/V_{REF} - Supply & Reference Voltage

DESCRIPTION

The **SP8537** is a 10 bit sampling ADC with a programmable two channel multiplexer and serial data interface. The ADC samples and converts 10 bits of data in 33.9 µS with a 5V supply voltage applied. The **SP8537** will also operate at a 3.3V supply at 150.2µS throughput. The device automatically shuts down to a ±0.5 µA (MAX) level as soon as the chip is deselected ($\overline{CS}$=1). Serial data output is available in an MSB first format.

FEATURES

Two program bits, which are shifted into the device prior to conversion, determine the input configuration. In the single ended MUX configuration the input signal will be applied to either channel 0 or channel 1 and will be ground referenced. The maximum full scale range is VCC. In the full differential mode, the signal will be applied between channel 0 and channel 1. The signals applied at each input may both be dynamic. This is in contrast with pseudo differential devices which must have input low held at a constant level during conversion. The converter will provide significant common mode rejection when used in full differential manner. Both inputs must remain between ground and VCC for proper conversion.

The device uses a capacitive DAC architecture which provides the sampling behavior. This results in full Nyquist performance at the fastest throughput rate (29.5 KHz) the device is capable of.

The power supply voltage is variable from 3.0V to 5.5V which provides supply flexibility. At the 5.0V supply level, conversion plus sampling time is 33.9µS and supply current is 250µA (1.25 mW). With a 3.3V supply the conversion plus sampling time is 150.2µS and current is reduced to 150µA (0.5 mW).

The device features automatic shutdown and will shutdown to a ±0.5 µA power level as $\overline{CS}$ is brought high (de-selected). Power is proportional to conversion duty cycle and varies from 250 µA at 34µS (Duty cycle = 100%) to 6.25µa at 1.4 ms (Duty cycle = 2.5%).

Examples:

Conversion rate	I_{CC} @ 5V	Duty Cycle
34 µS	250 µA	100%
68 µS	125 µA	50%
136 µS	62.5 µA	25%
1.4 mS	6.25 µA	2.5%

MUX ADDRESSING

Mux Addressing		Channel #		GND	Comments
SGL/$\overline{DIFF}$	ODD/SIGN	0	1		
0	0	V_{INH}	V_{INL}		Full Differential Mode
0	1	V_{INL}	V_{INH}		
1	0	V_{INH}		V_{INL}	Single Ended Mux Mode
1	1	V_{INH}		V_{INL}	

ADC TRANSFER FUNCTION

INPUT VOLTAGE (V_{INH}-V_{INL})*	INPUT VOLTAGE AT V_{CC}/V_{REF} = 5V	OUTPUT CODE
0 LSB	0V	0000000000
1 LSB	0.0049V	0000000001
512 LSB	2.5000V	1000000000
1022 LSB	4.9902V	1111111110
1023 LSB	4.9951V	1111111111

* See Mux Addressing Table for a definition of V_{INH} - V_{INL}.

The device is configured such that it delivers serial data MSB first requiring 15 clock periods for a full conversion. Please refer to the timing diagram.

Circuit Operation

The device will ignore any leading zeros applied to the DIN pin even if $\overline{CS}$ is low. After Chip Select Bar ($\overline{CS}$) is brought low and the START bit is clocked in to the converter, the conversion sequence is initiated. Two additional bits are clocked in immediately following the START bit: SGL/$\overline{DIFF}$ and ODD/SIGN. The second and third bits clocked in determine the MUX configuration (see MUX addressing table). Please refer to the timing diagram.

The SGL/$\overline{DIFF}$ bit when zero sets the input MUX for full differential mode and when one, sets the input MUX for single ended mode. The ODD/SIGN bit when zero sets channel zero as the positive input (ground referred for single ended operation and referred to channel one in differential mode). With the ODD/SIGN bit one, channel one will be the positive input (ground referred for single ended operation and referred to channel zero in differential mode).

The **SP8537** is a SAR converter with full differential multiplexed front end, capacitive DAC, precision comparator, Successive Approximations Register, control logic and data output register. After the input is sampled and held the conversion process begins. The DAC MSB is set and its output is compared with the signal input, if the DAC output is less than the input, the comparator outputs a one which is latched into the SAR and simultaneously made available at the ADC serial output pin. Each bit is tested in a similar manner until the SAR contains a code which represents the signal input to within $\pm$1/2 LSB. During this process the SAR content has been shifted out of the ADC serially. In the MSB first format the data will appear at the DOUT pin MSB through LSB in 15 clock periods. Note that the Chip Select Bar pin must be toggled high between conversions. The DOUT pin will be in a high impedance state whenever Chip Select Bar is high. After Chip Select Bar has been toggled and brought low again, the converter is ready to accept another START bit and begin a new conversion.

Full Differential Sampling

The **SP8537** can be configured for single-ended sampling (i.e. CH0-ground or CH1-ground) or full differential sampling (CH0-CH1 or CH1-CH0). In the full differential sampling configuration, both inputs are sampled and held simultaneously. Because of the balanced differential sampling, dynamic common mode noise riding along the input signal is cancelled above and beyond DC noise. This is a significant improvement over psuedo-differential sampling schemes, where the low side of the input must remain constant during the conversion, and therefore only DC noise (i.e. signal offset) is cancelled. If AC common mode noise is left to be converted along with the differental component, the output signal will be degraded.

Full differential sampling allows flexibility in converting the input signal. If the signal low-side is already tied to a ground elsewhere in the system, it can be hardwired to the low side channel (i.e. CH0 or CH1) which acts as a signal ground sense, breaking a potential ground loop. It is also possible to drive the inputs balanced differential, as long as both inputs are within the power rails. In this configuration, both the high and low signals have the same impedance looking back to ground, and therefore pick up the same noise along the physical path from signal source (i.e. sensor, transducer, battery) to converter. This noise becomes common mode, and is cancelled out by the differential sampling of the **SP8537**.

Layout Considerations

To preserve the high resolution and linearity of the **SP8537** attention must be given to circuit board layout, ground impedance and bypassing.

A circuit board layout which includes separate analog and digital ground planes will prevent the coupling of noise into sensitive converter circuits and will help to preserve the dynamic performance of the device. In single ended mode, the analog input signal should be referenced to the ground pin of the converter. This prevents any voltage drops that occur in the power supply's common return from appearing in series with the input signal.

In full differential mode, the high and low side board traces should run close to each other, with the same layout. This will insure that any noise coupling will be common mode, and cancelled by the converters (patent pending) full differential architecture.

If separate analog and digital ground planes are not possible, care should be used to prevent coupling between analog and digital signals. If analog and digital lines must cross, they should do so at right angles. Parallel analog and digital lines should be separated by a circuit board trace which is connected to common.

The **SP8537** VCC pin is also the reference pin for the device. This means that noise on the VCC pin will be proportionally represented as noise in the converters output data. A noise signal of 4.88mV (at a 5V supply) will produce 1 LSB of error in the output data. The VCC pin should be bypassed to the ground pin with a parallel combination of a 6.8µF tantalum and a 0.1µF ceramic capacitor. To maintain maximum system accuracy, the supply connected to the VCC pin should be well isolated from digital supplies and wide load variations. A separate conductor from the supply regulator to the A/D converter will limit the effects of digital switching elsewhere in the system. Power supply noise can degrade the converters performance. Especially corrupting are noise and spikes from a switching power supply.

To avoid introducing distortion when driving the A/D converter input, the input signal source should be able to charge the **SP8537's** equivalent 20 pF of input capacitance from zero volts to the signal level in 1.5 clock periods.
