

## Intelligent Sixfold Low-Side Switch

TLE 4216 G

Bipolar IC

### Features

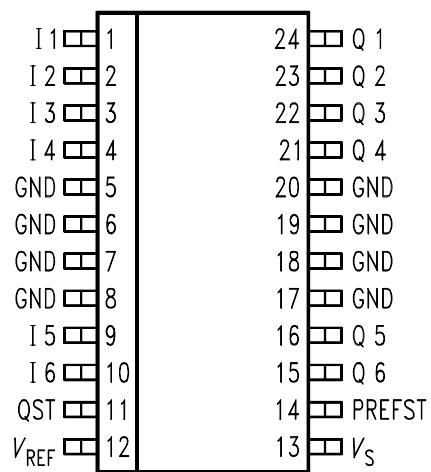

- Double low-side switch, 2 x 0.5 A
- Quad low-side switch, 4 x 50 mA
- Power limitation
- Open-collector outputs
- Overtemperature shutdown
- Status monitoring
- Shorted-load protection
- Integrated clamp Z-Diodes
- Temperature range – 40 to 110 °C

P-DSO-24-3

Type	Ordering Code	Package
TLE 4216 G	Q67000-A9108	P-DSO-24-3 (SMD)

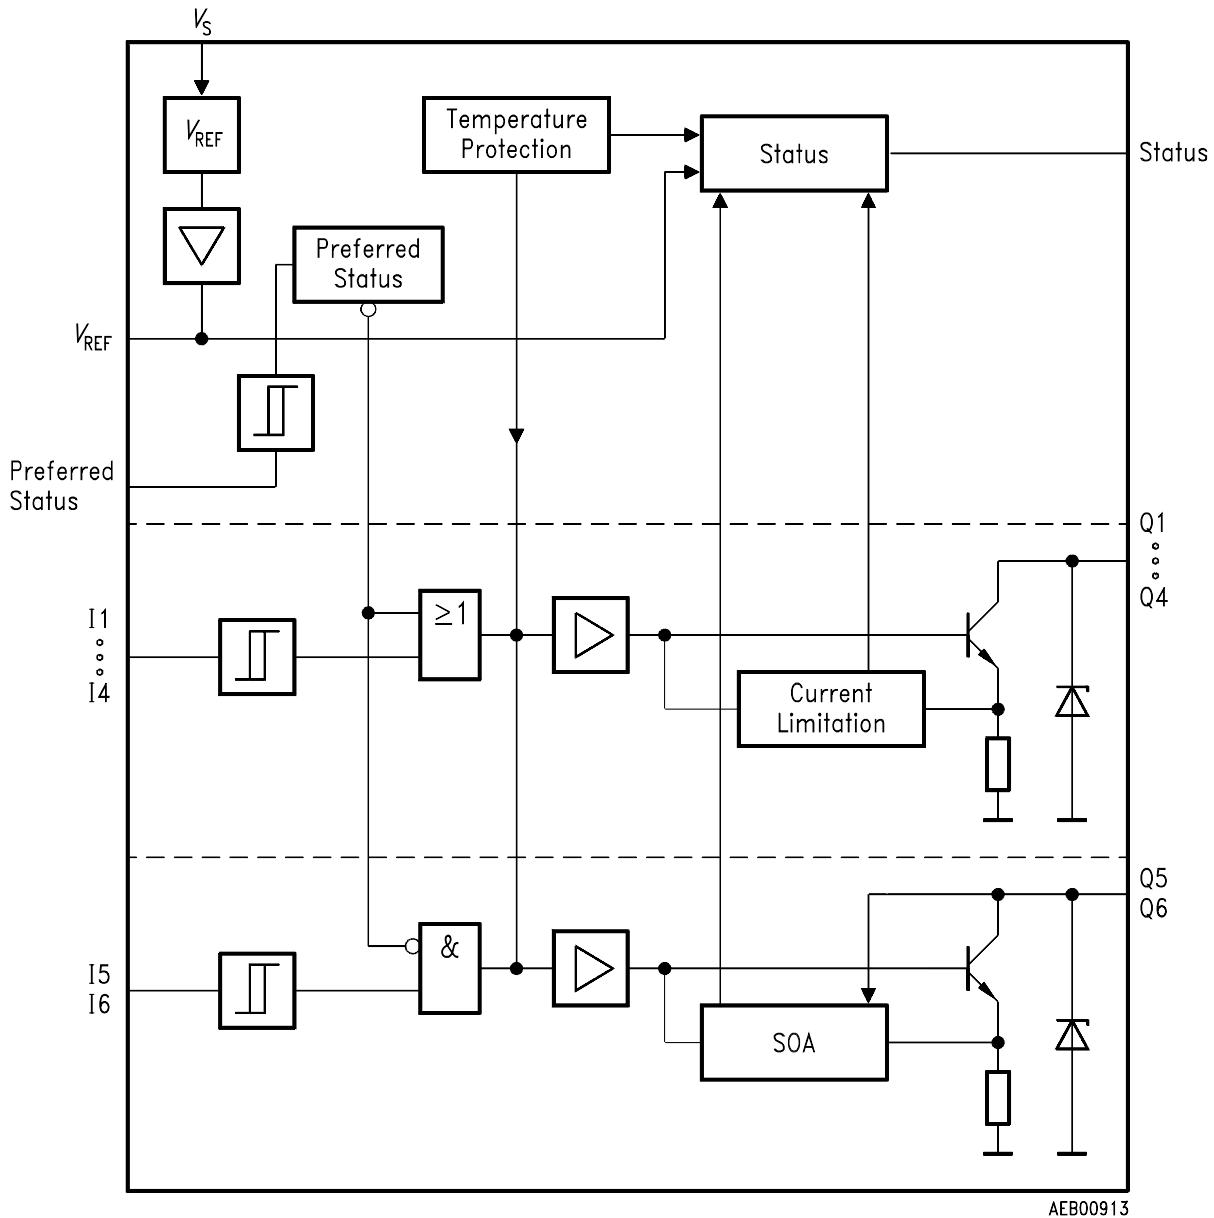

TLE 4216 G is an integrated, sixfold low-side power switch with power limiting of the 0.5 A outputs, shorted load protection of the 50 mA switches and Z-diodes on all switches from output to ground. TLE 4216 G is particularly suitable for automotive and industrial applications.

## Circuit Description

### Input Circuits

The control inputs and the preferred-state input consist of TTL-compatible Schmitt triggers with hysteresis. Driven by these stages the buffer amplifiers convert the logic signal necessary for driving the NPN power transistors.

### Switching Stages

The output stages consist of NPN power transistors with open collectors. Each stage has its own protective circuit for limiting power dissipation and shorted-load current, which makes the outputs shorted-load protected to the supply voltage throughout the operating range. Integrated Z-diodes limit positive voltage spikes that occur when inductive loads are discharged.

### Monitoring and Protective Functions

Each output is monitored in its activated status for overload. Furthermore, large parts of the circuitry are shutdown (control, output stages). The information from these malfunctions is ORed and applied to the status output. If several malfunctions appear simultaneously, the highest voltage level will dominate. The IC is also protected against thermal overload. If a chip temperature of typically 160 °C is reached, overtemperature is signalled on the status output. If the temperature continues to increase, all outputs are turned off at 170 °C.

If the minimum supply voltage for functioning is not maintained, the output stages become inactive. At a supply voltage of 2 to 4 V, the outputs are switched to a preferred state regardless of the level on pin PREFST. If the preferred state is to be maintained beyond this range, pin PREFST must be switched to low potential. Above a supply voltage of typical 3 V (max. 4 V) the preferred state is controlled by pin PREFST. From 4 to 5.2 V the logic operation of the outputs is guaranteed, but the status output cannot be evaluated. At a supply voltage of 5.2 to 30 V the full function is guaranteed.

## Application Description

Applications in automotive electronics require intelligent power switches activated by logic signals, which are shorted-load protected and provide error feedback.

The IC contains six power switches connected to ground (low-side switch). On inductive loads the integrated Z-diodes clamp the discharging voltage.

By means of TTL signals on the control inputs (active high) all six switches can be activated independently of another when a high level appears on the preferred-state input. When there is a low level on the preferred-state input, switches 1 to 4 are switched on, switches 5 and 6 are switched off regardless of the input level. The inputs are highly resistive and therefore must not be left unconnected, but should always be on fixed potential (noise immunity).

The status output signals the following malfunctions by analog voltage levels:

- Overload
- Overtemperature

When switching the maximum inductive loads, the maximum temperature  $T_j$  of 150 °C may be briefly exceeded. The IC will not be destroyed by this, but the restrictions concerning useful life should be observed.
