# **CMOS 8–Bit Microcontrollers**

# TMP90C848F

## 1. Outline and Characteristics

The TMP90C848F is a high-end 8-bit microcontroller developed in order to control power supply switching. With built-in high-speed 16-channel flush A/D converter (conversion time: 1.6 microseconds @10MHz\*), high-speed 8-channel PWM (8-bit resolution, oscillation frequencies of 80KHz, 160KHz, and 320KHz @10MHz\*) and a clock switching function, the TMP90C848F is ideal for controlling compact personal computer power supplies. (\* indicates a CPU clock with a 20MHz external clock (X1), which is divided by 2 during high-speed operation.)

The TMP90C848F is a CMOS 8-bit microcontroller which integrates an 8-bit CPU, ROM, RAM, an A/D converter, a multi-function timer, serial interface, high-speed PWM, and a clock switching function in a single chip.

The characteristics of the TMP90C848F are as follows: (Assuming high-speed external clock X1 = 20MHz, CPU clock fc = 10MHz)

- (1) Highly efficient instructions (TLCS-90 instruction sets) 163 types of basic instructions, including Multiplication/division arithmetic, 16-bit arithmetic operation, bit manipulation instruction.
- (2)Minimum instruction executing time: 400ns , ie.
- Built-in ROM: 8K bytes (3)

- (4) Built-in RAM: 512 bytes
- High-speed flash A/D converter (standard conversion (5) time: 1.6 microseconds, 16 channels)
- (6) General-purpose serial interface (1 channel)
- (7)High-speed PWM output (8 channels, effective only at high-speed clock operation) Oscillation frequency: 80KHz, 160KHz, 320KHz Resolution: 8 bits (50ns, 25ns, 12.5ns)
- (8) Multi-function 16-bit timer/event counter: 1
- (9) 8-bit timer: 4 channel
- (10)Input/Output port: 62 pins
- (11)Micro DMA function (11 channels)
- Watchdog timer function (internally connectable to (12)hardware reset)
- Interrupt function: 10 internal; 3 external (13)
- Clock switching function (high-speed/low-speed (14)switchina)
- Standby function (3 HALT modes, possible to disable (15)setting STOP mode.)
- Standby function (3 HALT modes, standby mode disable.) (16)

## 2. Pin Assignment and Functions

The assignment of input/output pins for TMP90C848F, their names and functions are described below.

#### 2.1 Pin Assignment

Figure 2.1 (1) shows pin assignment of the TMP90C848F.

Figure 2.1. Pin Assignment (80-pin Flat Package)

## 2.2 Pin Names and Functions

The names of input/output pins and their functions are summarized in Table 2.2.

Pin Name	No. of pins	I/O or tristate	Function
P00 ~ P07	8	I/O	Port 0: 8-bit I/O port. Each bit can be set for input or output.
P10 ~ P17	8	I/0	Port 1: 8-bit I/O port. Each bit can be set for input or output. Pull-up resistance included.
P20 ~ P27/	8	Output	Port 2: 8-bit output port.
HPWM0 ~ 7		Output	High-speed PWM output: High-speed 8
P30	1	Output	Port 30: 1-bit output port.
P31	1	Output	Port 31: 1-bit output port.
P32/	1	Output	Port 32: 1-bit output port.
TxD		Output	Used to transmit serial data.
P33/	1	Input	Port 33: 1-bit output port.
RxD		Input	Used to receive serial data.
P40 ~ P47	8	I/O	Port 4: 8-bit I/O port. Each bit can be set for input or output (P40 - P43 O.D. 4mA sink, P44 - 47 10mA source).
P50 ~ P57	8	Input	Port 5: 8- bit input port.
/AN0 ~ AN7		Input	Analog input: 8-bit analog input to the A/D converter.
P60 ~ 67	8	Input	Port 6: 8-bit input port.
/AN8 ~ AN15		Input	Analog input: 8-bit analog input the A/D converter.
P70 ~ P73	4	I/O	Port 7: 4-bit I/O port. Each bit can be set for input or output. Programmable pull-up resistant included.
P80	1	I/0	Port 80: 1-bit I/O port.
/T01		Output	Timer output 1: Used for timer 0 or timer 1 output.
P81	1	I/0	Port 81: 1-bit I/O port.
/T03		Output	Timer output 3: Used for timer 2 or timer 3 output.
P82	1	I/0	Port 82: 1-bit I/O port.
/INTO		Input	Interrupt request pin 0: Level/rising edge programmable interrupt request pin.
P83	1	I/0	Port 83: 1-bit I/O port.
/INT1		Input	Interrupt request pin 1: Rising/falling edge programmable interrupt request pin.
/TI4		Input	Timer input 4: Count input/capture trigger signal for timer 4.
P84	1	I/0	Port 84: 1-bit I/O port.
/INT2		Input	Interrupt request pin 2: Rising/falling edge programmable interrupt request pin.
/TI5		Input	Timer input 5: Count input/capture trigger signal for timer 5.
P85	1	I/O	Port 85: 1-bit I/O port.
/T04		Output	Timer output 4: Used as the timer 4 output.
ALE	1	Output	Address latch enable signal: No use.

## Table 2.2 Pin Names and Functions (1/2)

Pin name	No. of pins	I/O or tristate	Function				
CLK	1	Output	Clock output: Generates clock pulse at 1/4 frequency of clock oscillation. Pulled up internally during resetting.				
EA	1	Input	External access: Connected to the V <sub>CC</sub> pin when using the TMP90C848F with built-in ROM.				
RESET	1	Input	Reset: Initializes the TMP90C848F.				
X1/X2	2	I/0	High-speed crystal oscillator connection pin.				
X1′/X2′	2	I/0	Low-speed crystal oscillator connection pin.				
TEST1/TEST2	2	I/0	Testing pins: Connects directly TEST1 and TEST2 at a normal state operation.				
A VCC	1	_	Comparator power supply for the A/D converter.				
VREF	1	-	A/D converter reference voltage input.				
AVSS	1	-	Analog GND pin (0V)				
V <sub>CC</sub>	2	-	Power supply pin (+ 5V ± 10%)				
V <sub>SS</sub>	3	-	GND pin (0V)				

Table 2.2 (2/2)

# 3. Operation

This section explains the various functions and basic operations of the TMP90C848F.

## 3.1 CPU

The TMP90C848F has an internal built-in, high-performance 8-bit CPU. For a description of the CPU operation, see the book TLCS 90 Series CPU Core Architecture .

This section explains CPU functions dedicated to the TMP90C848F, which are not described in that book.

## 3.1.1 Clock

During high-speed operation of the TMP90C848F, the external clock (X1) divided by 2 is used as the CPU clock fc. During low-speed operation, the external clock (X1') is used as the CPU clock fc. In this manual, a clock indicates the CPU clock, unless stated otherwise.

#### 3.1.2 Reset

Figure 3.1 shows the basic timing of reset.

To reset the TMP90C848F, it is required that, 1) the power supply voltage is within the specified operating range, 2) the internal oscillator is stabe, and 3) the RESET input is kept at "0" at least 10 system clocks (10 states:  $2\mu$ sec at 10MHz system clock).

When reset is accepted, the following I/O ports are set to input status (with high impedance): port 0 (address data bus AD0

~ AD7), port 1 (address bus A8 ~ A15), port 4, port 7 and port 8. The output ports P30 ( $\overline{RD}$ ), P31 ( $\overline{WR}$ ) and P32, and CLK are set to "1", and ALE is cleared to "0". The input ports remain the same.

CPU registers and external memory are not changed. However, the program counter PC and the interrupt enable/ disable flag IFF are cleared to "0". Register A becomes undefined.

When the reset is released, instruction start executing from address 0000H.

Figure 3.1. TMP90C848F Reset Timing

#### 3.1.3 EXF (Exchange Flag)

The exchange flag EXF is inverted when the EXX instruction is executed to exchange data between the TMP90C848 main

registers and auxiliary registers. This flag is assigned to bit 1 at memory address FFD2H.

	$\sim$	7	6	5	4	3	2	1	0
	bit Symbol	WDTE	WDTP1	WDTP0	WARM	HALTM1	HALTM0	EXF	DRIVE
WDMOD	Read/Write	R/W	R/W		R/W	R/W		R	R/W
(FFD2H)	After reset	1	0	0	0	0	0	Un-defined	0
	Function	0: WDT Enable	WDT dete 00: 2 01: 2 10: 2 11: 2	<sup>16</sup> /fc <sup>18</sup> /fc <sup>20</sup> /fc	Warming up time (To release stop mode 0: 211/fc (1: 213/fc) (To switch clock 0: 211/fc (1: 213/fc)	Standby m 00: R 01: S 10: II 11: -	TOP DEL1	Inverts each time the EXX instructio n is executed.	1: Drives the pin even in the STOP mode

#### 3.2 Memory Map

The TMP90C848F can provide a maximum 64K byte program and data memory.

The program and data memories may be allocated to the addresses 0000H  $\sim$  FFFFH.

(1) Built-in ROM

The TMP90C848F has an internal 8-byte ROM. This ROM is located at addresses 0000H ~ 1FFFH. Program execution starts from address 0000H after a reset operation.

The addresses 0008H ~ 0068H in the internal ROM area are used as the interrupt processing entry area.

(2) Built-in RAM

TMP90C848F contains a 512-byte RAM which is allo-

cated to the addresses FFC0H ~ FFBFH. The CPU can also access some portions of the RAM (192 byte area FF00H ~ FFBFH) using short instruction codes in the direct addressing mode.

Addresses of FF18H  $\sim$  FF6DH this RAM area are used as the parameter area for micro DMA processing. (This area can freely be used when the micro DMA function is not used.)

(3) Built-in I/O

TMP90C848F uses 56 bytes of the address space as a built-in I/O area. The area is allocated to the addresses FFC0H ~ FFF7H. The CPU can access the built-in I/O using short instruction codes in the direct addressing mode.

Figure 3.2 shows the memory map and the access ranges of the CPU for each addressing mode.

Figure 3.2. TMP90C848F Memory Map

#### **3.3 Interrupt Functions**

The TMP90C848F provides the two processing modes for internal and external interrupt requests; a general-purpose interrupt processing mode and a micro DMA processing mode in which the CPU can automatically transfer data.

Immediately after a reset is released, all the responses to

interrupt requests are set in the general-purpose interrupt processing mode. Using DMA enable/disable register which will be described later, each interrupt request can be set to the micro DMA processing mode.

Figure 3.3 (1) shows a flowchart of the interrupt response sequence.

Figure 3.3 (1). Interrupt Response Flowchart

When an interrupt is generated, it is reported to the CPU via the built-in interrupt controller. The CPU starts the interrupt processing if it is a non-maskable or maskable interrupt requested in the El state (interrupt enable/disable flag (IFF bit of the F register) = "1").

However, a maskable interrupt requested in the DI state (IFF = "0") is ignored and not accepted. (The CPU samples interrupt requests at the fall edge of CLK signal of the last bus cycle of each instruction.)

When an interrupt is accepted, the CPU first reads the interrupt vector from the built-in internal interrupt controller to find out the source of the interrupt request.

Then, the CPU checks if the request should be processed in the general-purpose interrupt processing mode or micro DMA processing mode, and proceeds to the appropriate process.

The interrupt vector is read in an internal operation cycle, so the bus cycle results in dummy cycles.

#### 3.3.1 General Purpose Interrupt Processing

Figure 3.3 (2)shows the flow of general-purpose interrupt processing.

The CPU first saves the contents of the program counter PC and register AF (including the interrupt enable/disable flag just before the interrupt is issued) into the stack, and resets the interrupt enable/disable flag IFF to "0" (interrupt disable). Finally, it transfers the contents "V" of interrupt vector to the program counter and jumps to the interrupt processing program.

The overhead for the entire process from accepting an interrupt to jumping to an interrupt processing program is 20 states.

Figure 3.3 (2). General Purpose Interrupt Processing Flowchart

The interrupt processing program ends with RETI instruction for both non-maskable and maskable interrupts.

When this instruction is executed, the contents of the program counter PC and register AF will be restored from the stack (returns to the interrupt enable/disable flag just before the interrupt was issued).

When the CPU reads an interrupt vector, the interrupt request source acknowledges that the CPU accepts the request, and clears the request.

Non-maskable interrupts cannot be disabled by program.

Maskable interrupts, however, can be enabled or disabled by programming. An interrupt enable/disable flip-flop (IFF) is provided on the bit 5 of Register F in the CPU.

Interrupts are enabled by setting IFF to "1" with the EI instruction and disabled by resetting IFF to "0" with the DI instruction. IFF is reset to "0" by the reset operation or the acceptance of any interrupt (including non-maskable interrupts). Interrupt enabled with the EI instruction become effective

when the instruction after the El is executed. Table 3.3 (1) shows the interrupt sources.

Priority order	Туре	Interrupt source	Vector value	Start address of general- purpose interrupt processing	Start address of Micro DMA processing parameter
1	Non-	SWI instruction	08H	0008H	_
2	maskable	INTWD (watchdog)	10H	0010H	-
3		INTO (External input 0)	18H	0018H	FF18H
4		INTTO (Timer 0)	20H	0020H	FF20H
5		INTT1 (Timer 1)	28H	0028H	FF28H
6		INTT2 (Timer 2)	30H	0030H	FF30H
7		INTT3 (Timer 3)	38H	0038H	FF38H
8	Maskable	INTT4 (Timer 4)	40H	0040H	FF40H
9		INT1 (External input 1)	48H	0048H	FF48H
10		INTT5 (Timer 5)	50H	0050H	FF50H
11		INT2 (External input 2)	58H	0058H	FF58H
12		INTRX (Serial receiving end)	60H	0060H	FF60H
13		INTTX (Serial transmission end)	68H	0068H	FF68H

Table 3.3 (1) Interrupt Sources

The "priority order" in the Table 3.3 (1) shows the order of the interrupt source to be acknowledge by the CPU when more than one interrupt are requested at one time.

If interrupt request of 4th and 5th orders are generated at the same time, for example, an interrupt of the "5th" priority is acknowledged after the "4th" priority interrupt processing has been completed by a RETI instruction. However, the "5th" priority interrupt can be acknowledged immediately by executing an El instruction in a program that processes the "4th" priority interrupt.

The built-in interrupt controller only determines the priority of the interrupt sources which are to be accepted by the CPU when two or more interrupts are requested at a time.

It is, therefore, unable to compare the priority of interrupt being executed with the one being requested.

To enable other interrupt while an interrupt is being processed, set an interrupt enable/disable flag for the interrupt source to be enabled and execute El instruction.

#### 3.3.2 Micro DMA Processing

Figure 3.3 (3) shows the flowchart of the micro DMA processing. The CPU first loads parameters (addresses of source and destination, and transfer mode) necessary for the data transfer between memories from an address modified by an interrupt vector value. After the data transfer between memories according to these parameters, the parameters are updated and saved into the original locations. The CPU then decrements the number of transfers, and completes the micro DMA processing unless the result is "0". If the number of transfers become "0", the CPU proceeds to the general-purpose interrupt handling described in the previous section.

Figure 3.3 (3). Micro DMA Processing Flowchart

Since most interrupt processing involves only simple transfers, the micro DMA processing executes such processing only by hardware. Accordingly, the micro DMA processing can handle the interrupt in a higher speed than the conventional process using software. Naturally, the CPU registers are not affected by the micro DMA processing.

Figure 3.3 (4) shows the functions of parameters used in the micro DMA processing.

Figure 3.3 (4). Parameters for Micro DMA Processing

Parameters for micro DMA processing are located in the internal RAM area (See Table 3.3 (1) Interrupt Sources). The start address of each parameter becomes "FF00H + interrupt vector value", 6 bytes space are used for the parameter. When micro DMA processing is not used, the area can be freely used as user memory.

The parameters consist of the number of transfer, destination of addresses and source, and transfer mode. The number of transfer specifies the number of data transfers accepted by the micro DMA processing. A single time micro DMA processing transfers 1-byte or 2-byte data. The number of transfers is 256 when the number of transfers value is "00H". Both the destination and source addresses are specified by 2-byte data. The address space available for the micro DMA processing ranges from  $0000H \sim FFFFH$ .

Bits 0 and 1 of the transfer mode indicates the mode updating the source and/or destination, and the bit 2 indicates the data length (one byte or two bytes).

Table 3.3 (2) shows the relation between the transfer modes and the decremented/incremented values of the destination/source addresses.

Transfer Mode	Function	Destination address	Source address
000	1-byte transfer: Fix the current destination /source addresses	0	0
001	1-byte transfer: Increment the destination address	+1	0
010	1-byte transfer: Increment the source address	0	+1
011	1-byte transfer: Decrement the source address	0	-1
100	2-byte transfer: Fix the current destination /sourc addresses	0	0
101	2-byte transfer: Increment the destination address	+2	0
110	2-byte transfer: Increment the source address	0	+2
111	2-byte transfer: Decrement the source address	0	-2

In the 2-byte transfer mode, data are transferred as follows:

(Destination address)  $\leftarrow$  (Source address) (Destination address + 1)  $\leftarrow$  (Source address + 1)

Similar data transfers are made in the modes that "decrement the source address", but the updated address are different as shown in the Table 3.3 (2).

Address increment/decrement modes are applied to memory address space and fixed addressing modes are applied to the I/O address space. Because of that, the micro DMA was designed for both I/O to memory transferes and memory to I/O transfers.

Figure 3.3 (5) shows an example of the micro DMA processing that handles data receiving of internal serial I/O.

This is an example of executing "an interrupt processing program after serial data receiving" after receiving 7-frame data (Assume 1 frame = 1 byte for this example) and saving them into the memory addresses from FF00H to FF06H.

CALL	SIOINIT	;	Initial setting for serial receiving.
SET	3,(0FFF6H)	;	Enable an interrupt for serial data receiving.
SET	3,(OFFF8H)	;	Set the micro DMA processing mode for serial receiving interrupt.
LD	(OFF60H),7	;	Set the number of transfers $= 7$ .
LDW	(OFF61H),OFF00H	;	Set FF00H for the destination start address.
LDW	(OFF63H),OFFDFH	;	Set FFDFH for the source (serial receiving buffer) address.
LD	(OFF65H),1	;	Set the transfer mode (1-byte transfer; increment destination address).

Figure 3.3 (5). Example of Micro DMA Processing

For the bus operation in the general-purpose interrupt processing and the micro DMA processing, see "Table 1.4 (2) Bus Operation for Executing Instructions" in the previous section "TLCS-90 CPU".

Execution time for micro DMA processing (when decre-

mented number of transfers is not zero) is 46 states (5.75 $\mu$ s at 16MHz oscillation), regardless of whether 1-byte/2-byte transfer mode is used.

Figure 3.3 (6) shows the flowchart of overall interrupt processing.

Figure 3.3 (6). Interrupt Processing Flowchart

#### 3.3.3 Interrupt Controller

Figure 3.3 (8) shows the block diagram of interrupt circuit. The left half of this diagram shows the interrupt controller, and the right half includes the CPU's interrupt request signal circuit and HALT release signal circuit.

The interrupt controller has an interrupt request flip-flops, interrupt enable/disable flag, and micro DMA enable/disable flag for each o interrupt channel (total; 13 channels). The interrupt request flip-flop latches an interrupt request when it is issued from the peripheral devices. This flip-flop is reset to "0" when reset operation or interrupt is accepted by the CPU and the vector of that interrupt channel is read by the CPU, or when the CPU executes an instruction that clears the interrupt request for the specified channel (write "vector divided by 8" into the memory address FFEAH). For example, when executing

LD (0FFEAH), 38H/8,

the interrupt request flip-flop of the interrupt channel "INTT3" whose vector is 38H will be reset to "0". (Write to FFEAH even when clearing the interrupt request flag that is assigned to FFEBH.)

The status of an interrupt request flip-flop is can be known by reading the memory address FFEAH or FFEBH. "0" denotes there is no interrupt request, and "1" denotes that an interrupt is requested. Figure 3.3 (7) shows the bit configuration of the interrupt request flip-flops.

Note: When "vector value/8" is written in memory address FFEAH, the specified interrupt request flag will be cleared.

### Figure 3.3 (7). Interrupt Request Flip-flops

Figure 3.3 (8). Block Diagram of Interrupt Controller

The interrupt enable/disable flags provided for all interrupt request channels are assigned to the memory address FFF6H or FFF7H. Interrupts for a channel are enabled by setting the flag to "1". The flags are cleared to "0" by resetting.

Clear the interrupt enable flag in the DI status.

The micro DMA enable/disable flag also provided for each interrupt request channel is assigned to the memory address

FFE8H or FFE9H. The interrupt processing for each channel is placed in the micro DMA processing mode by setting this flag to "1". This flag is cleared to "0" (general-purpose interrupt processing mode) by resetting.

Figure 3.3 (9) shows the bit configurations for interrupt enable/disable flag and micro DMA enable/disable flag. External interrupt features are as follows.

Interrupt	Common pin	Mode	How to set
INTO	P82	Level	INTEH <edge> = 0</edge>
	F OZ	 Rise edge	INTEH <edge> = 0</edge>
INIT4	Doo	 Rise edge	T4MOD <capm1, 0=""> = 0, 0 or 0, 1 or 1, 1</capm1,>
INT1	P83	Fall edge	T4MOD <capm1, 0=""> = 1, 0</capm1,>
INT2	P84	 Rise edge	-

For the pulse width for the external interrupts, refer to "4.7 Interrupt Operations".

Be careful that the following two are exceptional circuits.

INTO Level mode	As the INTO is not an edge based interrupt, the interrupt request flip-flop function is cancelled and thus an interrupt request from peripheral devices passes through S input of the flip-flop to become Q output. When the mode is changed over (from edge type to level type), the previous interrupt request flag will be cleared automatically. When the mode is changed from level to edge, the interrupt request flag set in the level mode is not cleared. Thus, use the following sequence to clear the interrupt request flag. DI SET 6, (OFFE7H) : Switch the mode from level to edge LD (OFFEAH), 03H : Clear interrupt request flag El
INTRX	The interrupt request flip-flop is cleared only by reset or reading the serial channel receiving buffer, and cannot by an instruction.

Figure 3.3 (9). Interrupt Enable/Disable Flags

→ INTO DMA enable/disable flag

Figure 3.3 (10). Micro DMA Enable/Disable Flag

#### **3.4 Clock Switching Function**

The TMP90C848F has the following clock modes.

① Low speed clock mode

The high-speed clock stops and the CPU operates in low-speed clock mode.

② High-speed clock mode

Both the high-speed clock and the low-speed clock generate, and the CPU operates in high-speed clock mode.

#### 3.4.1 Operation

The clock mode setting register (CLKMOD) is assigned at bit 0 of the memory address "FFC7H" in the internal I/O register area.

Switching between low-speed clock mode and high-speed clock mode is controlled by commands.

When resetting DCLK (bit 0 of the clock mode setting register CLKMOD) is initialized to "0", and the CPU operates in lowspeed clock mode.

In low-speed clock mode, SLS (bit 3 of the clock mode register CLKMOD) is set to "0"; and in high-speed clock mode, "1".

Because the watchdog timer counter is also used as the warm-up timer, the watchdog timer counter is cleared when the clock mode is switched from low-speed to high-speed.

		7	6	5	4	3	2	1	0
	bit Symbol			STBYD	WDRESE	SLS			DCLK
CLKMOD (FFC7H)	Read/Write			R/W	R/W	R			w
(110/11)	After reset			1	1	0			0
	Function			1: Standby enable 0: Standby disable	1: Interrupt 0: RESET	0: low- speed 1: high- speed			0: low- speed 1: high- speed

Switching from low-speed clock mode to high-speed clock mode

In order to switch to WARM (bit 4 of watchdog mode register address FFD2), set the warm-up period to 0: 2<sup>11</sup>/fc or 1: 2<sup>13</sup>/ fc, and DCLK to "1". After completing the specified warm-up period, the clock mode is switched to high-speed clock mode. In this case, the low-speed clock does not stop.

# Switching from high-speed clock mode to low-speed clock mode

This clock mode is switched to low-speed by setting DCLK to "0". The high-speed clock stops.

#### **3.5 Standby Function**

When a HALT instruction is executed, the TMP90C848F enters the RUN, IDLE1, or STOP mode according to the contents of the halt mode setting register. The features are as follows:

- (1) RUN: Only the CPU halts, and the power consumption remains unchanged.
- (2) IDLE1: Only the internal oscillator operates, while all other internal circuits halt. Power consumption is 1/10 or less than that during normal operation.
- (3) STOP: All internal circuits halt, including the internal oscillator. The power consumption is extremely reduced.

The HALT mode setting register WDMOD <HALTM 1, 0> is assigned to the bits 2 and 3 of memory address FFD2H in the built-in I/O register area (all other bits are used to control other block functions). The RUN mode ("00") is entered by resetting.

These HALT states can be released by resetting an interrupt or resetting. Table 3.4 (2) shows how to release the HALT state. If the CPU is in the El state for non-maskable or maskable interrupt, the interrupt will be acknowledged by the CPU and the CPU starts interrupt processing. If the CPU is in the DI state for maskable interrupt, the CPU restarts execution from the instruction following HALT instruction, but the interrupt request flag remains at "1".

Even when HALT state is released by reset operation, the state (including the built-in RAM) just before entering the HALT state can be retained. However, if HALT instruction has already been executed in the built-in RAM, the RAM contents may not be retained.

	$\square$	7	6	5	4	3	2	1	0

Figure 3.5 (1). HALT Mode Setting Register

#### 3.5.1 Standby Disable Function

The standby disable function prevents the watchdog timer from being stopped and enabled it to escape from a malfunction (runaway), when the TMP90C848F enters standby mode because of a CPU runaway.

STBYD (bit 5 of clock mode register FFC7H) is reset to "0", standby mode is disabled and the TMP90C848F does not enter standby mode even if the HALT instruction is executed. The watchdog timer continues its operation, without stopping.

When standby mode is not used, STBYD is reset to "0". In this case, although standby mode is set by the halt mode register (HALTM), executing the halt instuction does not access standby mode (it accesses RUN mode).

Once STBYD is reset to "0", it cannot be set to "1" (standby mode enable). Standby mode becomes effective only by resetting. Table 3.5 (1) shows a standby state when the standby disable function is executed.

		7	6	5	4	3	2	1	0

0	0	Х	Х			

#### Table 3.5 (1) Standby State at Standby Disable Function

O: Executes specified standby mode.

X: Switched to RUN mode.

#### 3.5.2 RUN Mode

Figure 3.5 (3) shows the timing for releasing the halt state by interrupts in the RUN/IDLE2 mode.

In the RUN mode, the system clock in the MCU continues

to operate after the HALT instruction is executed. Only the CPU stops executing the instruction. Until the halt state is released, the CPU repeats dummy cycles. In the halt state, interrupt request is sampled with the rising edge of CLK signal.

Figure 3.5 (3). HALT Release Timing Using Interrupts in RUN Mode

## 3.5.3 IDLE 1 Mode

Figure 3.5 (4) shows the timing for releasing the HALT state by interrupts in the IDLE1 mode.

In the IDLE1 mode, only the internal oscillator operates, the

system clock inside MCU stops, and CLK signal is fixed to "1". In the HALT state, interrupt request are sampled asynchronously with the system clock, whereas the HALT release (restart of operation) is performed synchronously with it.

Figure 3.5 (4). HALT Release Timing Using Interrupts in IDLE1 Mode

#### 3.5.4 STOP Mode

Figure 3.5 (5) shows the timing of HALT release caused by interrupts in STOP mode.

In the STOP mode, all internal circuits stop including the internal oscillator. When the STOP mode is activated, all pins except special ones are put in the high-impedance state, isolated from the internal operation of MCU. Table 3.4 (1) shows the state of each pin in the STOP mode. However, if WDMOD <DRVE> (drive enable: bit 0 of memory address FFD2H) of the built-in I/O register is set to "1", the pre-halt state of the pins can be retained. The register is cleared to "0" by reset operation.

When the CPU accepts an interrupt request, the internal oscillator first restarts. However, to get the stabilized oscillation, the system clock starts its output after the time set by the warming up counter has passed. WDMOD <WARM> (warming up: bit 4 at memory address FFD2H) is used to set the warming up time. Warming up is executed for 2<sup>14</sup> clock oscillation time when this bit is set to "0", while 2<sup>16</sup> clock oscillation time when set to "1". This bit is initialized to "0" by reset operation.

Figure 3.5 (5). HALT Release Timing Using Interrupt in STOP Mode

The internal oscillator can be also restarted by inputting RESET signal at "0" to the CPU.

However, the warming-up counter remains inactive in order to make the CPU rapidly operate when the power is turned on. Accordingly, wrong operation may occur due to unstable clocks immediately after the internal oscillator has restated. To release the HALT state by resetting the STOP mode, RESET signal must be kept at "0" for a sufficient period of time.

### **3.6 Function of Ports**

The TMP90C848F has a total of 62 I/O port pins. These ports function not only as the general-purpose I/O ports but also as

the I/O ports for the internal CPU and built-in I/O. Table 3.6 shows the functions of these port pins.

Port Name	Pin Name	No. of Pins	Direction	Direction Setting Unit	Pin Name for Internal Function
Port 0	P00 ~ P07	8	I/O	Bit	-
Port 1	P10 ~ P17	8	I/O	Bit	-
Port 2	P20 ~ P27	8	Output	Bit	HPWM0 ~ HPWM7

## Table 3.6 Functions of Ports

These port pins function as the general-purpose input/ output ports by resetting. The port pins, for which input or output is programmably selectable, function as input ports by resetting. A separate program is required to use them for an internal function.

### 3.6.1 Port 0 (P00 ~ P07)

Port 0 is the 8-bit general-purpose I/O port P0, each bit of which can be set independently for input or output. The control

register POCR is used to set input or output. Reset operations clear all output latch and control register bits to "0" and set port 0 to the input mode.

Figure 3.6 (1). Port 0 (P00 ~ P07)

#### 3.6.2 Port 1 (P10 ~ P17)

Port 1 is an 8-bit general-purpose I/O port (P1: memory address FFC2H) which can be set to input or output bits. The port 1 control register (P1CR: memory address FFC3H) is

used to set input or output.

Executing the reset operations clears all output latch and control register bits to "0" and sets all bits of port 1 to input mode.

Figure 3.6 (2). Port 1 (P10 ~ P17)

Read modify write are not possible.

### 3.6.3 Port 2 (P20 ~ P27)

Port 2 is an 8-bit port (P2: memory address FFC4H). Executing the reset operation sets all output latch bits to "1" and sends "1" from the port.

In addition to the output port functin, port 2 also functions

as the high-speed PWM output (HPWM0 ~ HPWM7). This is specified by the function register (P2FR: memory address FFC5H). The output port and high-speed PWM output can be selected by bits. Executing the reset operation resets all function register bits to "0" and sets the port to output port mode.

#### 3.6.4 Port 3 (P30 ~ P33)

Port 3 is a 4-bit general-purpose I/O port (P3: memory address FFC6H) which can be set to input or output by bits. Executing the reset operation sets all output latch bits to

"1" and sends "1" to the output port.

In addition to the I/O port function, P32 ~ P33 also function

as the I/O port for the internal serial interface, and P30 ~ P31 function as the extremal memory control. This is specified by the function register (P3FR: memory address FFC8H). Executing the reset operation resets all function register bits to "0" and sets the port to general-purpose I/O port mode.

## 3.6.5 Port 4 (P40 ~ 47)

Port 4 is an 4-bit general-purpose I/O (P4: memory address FFC9H) which can be set to input or output by bits. The port 4 control register (P4CR: memory addres FFCAH) is used to set

input or output.

Executing the reset operation sets all output latch bits to "1", resets all control register bits to "0", and sets the port to input port mode.

Figure 3.6 (6) A. Port 4

Port 4 is an open drain pin (as shown in Figure 3.6 (6) B): P40 ~ P43 function as an open drain sink, and P44 ~ P47

function as an open drain source.

## 3.6.7 Port (P70 ~ P73)

Port 7 is a 4-bit general-purpose I/O port, each bit of which can be set for input or output. The control register P67CR <P73C ~ P70C> is used to set for input or output. When

reset, this control register will be cleared to "0", placing the port 7 in the input mode. Each port is with programmable pullup (FET).

Figure 3.6 (11). Registers for Port 7

## 3.6.8 Port 8 (P80 ~ P85)

Port 8 is a 6-bit general-purpose I/O port (P8: memory address FFCFH). The port 8 control register (P8CR: bits 0 ~ 5 memory address FFD0) is used to set input or output.

In addition to the general-purpose port function, port 8 also functions as an interrupt request input, clock input for a timer/event counter, and timer output. (1) P80, P81, P85

P80, P81 and P85 are general-purpose I/O ports and are also used as timer output pins (T01, 3, 4). The timer output function is set by the function register (P8FR: bits 0, 1 and of memory address FFD1H).

Figure 3.6 (12). Port 8 (P80, P81, P85)

# TMP90C848F

#### (2) P82/INT0

P82 is a general-purpose I/O port and is also used as an external interrupt request input pin INTO. INTO

selects either an "H" level interrupt or a rising edge interrupt from the control register (INTEH: bit 6 of memory address FFE7H).

Figure 3.6 (13). Port 8 (P82)

## (3) P83/INT1/TI4

P83 is a general-purpose input port and is also used as an external interrupt request input pin INT1 an a clock input pin Tl4 for a timer/event counter. P83 has a built-in zero-cross detection circuit which enables it to detect a zero cross, when it is connected to an external capacitor. The zero-cross detection function can be set to disable/enable by the function register (P8FR: bit 3 of memory address FFD1H). Executing the reset operation resets the control register to "0" and sets the zero-cross detection function to disable. The rising/falling edge interrupt control is assigned to bit 3/ 4 of the 16-bit timer T4MOD register, which is also used for a capture control.

#### (4) P84/INT2/TI5

P84 is a general-purpose I/O port, similar to P83, and is also used as an external interrupt request input pin INT2 and a clock input pin TI5 for a timer/event counter. P84 also has a built-in zero-cross detection circuit which is set to disable/enable by the function register (P8FR: bit 4 of memory address FFD1H). When reset, the port is set to disable.

Figure 3.6 (14). Port (P83, P84)

Figure 3.6 (15). Registers for Port 8

# 3.7 8-bit Timers

The TMP90C848F contains four 8-bit timers (timers 0, 1, 2 and 3), each of which can be operated independently. The cascade connection allows these timers to be used as 16-bit timers.

The following four operating modes are provided for the 8-bit timers:

- 8-bit interval timer mode (4 timers)
- 16-bit interval timer mode (2 timers)
- 8-bit programmable square wave pulse generation (PPG: variable duty with variable cycle) output mode (2 timers)
- 8-bit pulse width modulation (PWM: variable duty constant with cycle) output mode (2 timers)

The upper two can be combined (two 8-bit timers and one 16-bit timer).

Figure 3.7 (1) shows the block diagram of the 8-bit timer (timer 0 and timer 1).

Timer 2 and timer 3 have the same circuit configuration as timer 0 and timer 1. Each interval timer consists of an 8-bit upcounter, 8-bit comparator, and 8-bit timer register. Besides, one timer flip-flop (TFF1 or TFF3) is provided for each pair of Timer 0 and timer 1 as well as timer 2 and timer 3.

Among the input clock sources for the interval timers, the internal clocks of ØT1, ØT4, ØT16, and ØT256 are obtained from the 9-bit prescaler shown in Figure 3.7 (2).

The operation modes and timer flip-flops of the 8-bit timer are controlled by five control registers T01MOD, T23MOD, TFFCR, TRUN, and TRDC.

Figure 3.7 (1). Block Diagram of 8-bit Timers (Timers 0 and 1)

#### ① Prescaler

This 9-bit prescaler generates the clock input to the 8bit, 16-bit timer/event counters, and baud rate generators by further dividing the fundamental clock (fc) after it has been divided by 4 (fc/4).

Among them, 8-bit timer uses 4 types of clock: øT1,

øT4, øT16 and øT256.

This prescaler can be run or stopped by the timer operation control register TRUN <PRRUN>. Counting starts when <PRRUN> is set to "0". Resetting clears <PRRUN> to "0", which clears and stops the prescaler.

Figure 3.7 (2). Prescaler

## 2 Up-counter

This is an 8-bit binary counter which counts up by the input clock pulse specified by the timer 0/timer 1 mode register T01MOD and timer 2/timer 3 mode register T23MOD.

The input clock of timer 0 and timer 2 is selected from the external clock from TIO pin (commonly used as P44) and TI2 pin (commonly used as P45 or INT0) and the three internal clocks øT1 (8/fc), øT4 (32/fc), and øT16 (128/fc), according to the set value of T01MOD and T23MOD.

The input clock of timer 1 and timer 3 differs depending on the operation mode. When set to 16-bit timer mode, the overflow output of timer 0 and timer 2 is used as the input cock.

When set to any other mode than 16-bit timer mode, the input clock is selected from the internal clocks ØT1 (8/fc), ØT4 (32/fc), ØT16 (128/fc), and ØT256 (2048/fc) as well as the comparator output (match detection signal) of timer 0 and timer 2, according to the set value of T01MOD and T23MOD.

Example: When T01MOD <T01M1,0> = 01 the overflow output of timer 0 becomes the input clock of Timer 1. (16-bit timer.) When T01MOD <T01M1, 0> = 00 and T01MOD <T1CLK1,0> = 0, 1, øT1 (8/fc) becomes the input clock to timer 1. Operation mode is also set by the T01MOD and T23MOD. When reset, it is initialized to T01MOD <T01M1, 0> = 00, T23MOD <T23M1, 0> = 00, whereby the up-counter is placed in the 8-bit timer mode.

The counting, halt, and clear of up-counter can be controlled for each interval timer by the timer operation control register TRUN. When reset, all up-counters will be cleared to stop the timers.

#### ③ Timer register

This is an 8-bit register for setting an interval timer. When the set value of timer registers TREG0, TREG1, TREG2 and TREG3 matches the value of up-counter, the comparator match detect signal becomes active. If the set value is 00H, this signal becomes active when the up-counter overflows.

Timer registers TREG0 and TREG2 are of double buffer structure, each of which makes a pair with register buffer.

The TREG0 and TREG2 control whether the double buffer should be enabled or disabled through the timer register double buffer control register TRDC <TRODE, TR2DE>. It is disabled when <TR0DE>/TR2DE> =0, and enabled when they are set to 1.

The timing to transfer data from the register buffer to the timer register in the double buffer enable state is the moment  $2^n$  - 1 overflow occurs in PWM mode or the moment compare cycles will be equal in the PPG mode.

When reset, it will be initialized to <TRODE>/TR2DE> = 0 to disable the double buffer. To use the double buffer, write data in the timer register, set <TR0DE> and TR2DE> to 1, and write the following data in the register buffer.

## Figure 3.7 (3). Configuration of Timer Registers 0 and 2

Note: Timer register and the register buffer are allocated o the same memory address. When <TRODE>/TR2DE> = 0, the same value is written in the register buffer as well as the timer register, while when <TRODE>/TR2DE> = 1 only the register buffer is written.

The memory address of each timer register is as follows.

TREG2: FFD6H TREG3: FFD7H

TREG0: FFD4H TREG1: FFD5H

All the registers are write-only and cannot be read.

Figure 3.7 (4). Timer 0/Timer 1 Mode Register (T01MOD)

Figure 3.6 (5). Timer 2/Timer 3 Mode Register (T23MOD)

Figure 3.7 (6). 8-Bit Timer Flip-flop Control Register (TFFCR)

Figure 3.7 (7). Timer Operation Control Register (TRUN)

Figure 3.7 (8). Timer Register Double Buffer Control Register (TRDC)

(4) Comparator

> A comparator compares the value in the up-counter with the values to which the timer register is set. When they match, the up-counter is cleared to zero and an interrupt signal (INTTO ~ INTT3) is generated. If the timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

(5) Timer flip-flop (timer F/F)

> The status of the timer flip-flop is inverted by the match detect signal (comparator output) of each interval timer and the value can be output to the timer output pins TO1 (also used as P80) and TO3 (also used as P81). A timer F/F is provided for each pair of timer 0 and timer 1 as well as that of timer 2 and timer 3 and is called TFF1 and TFF3. TFF1 is output to TO1 pin, while TFF3 is output to TO3 pin.

The operation of 8-bit timers will be as follows:

8-bit Timer Mode (1)

> Four interval timers 0, 1, 2 and 3 can be used independently as an 8-bit interval timer. All interval timers operate in the same manner, and thus, only the operation of timer 1 will be explained below.

① Generating interrupts in a fixed cycle To generate timer 1 interrupt at constant intervals

using timer 1 (INTT1), first stop timer 1, then set the operation mode, input clock, and synchronization to T01MOD and TREG1, respectively. Then, enable interrupt INTT1 and start the counting of timer 1.

Example: To generate timer 1 interrupt every 40 microseconds at fc = 10MHz, set each register in the following manner.

Stop timer 1, and clear it to "0". Set the 8-bit timer mode, and select  $\phi$ T1 (0.8  $\mu$ s @ fc = 10 MHz) as the input clock. Set the timer register at 40  $\mu$ s  $\phi$ T1 = 50. Enable INTT1. Start timer 1 counting.

P4CR ←		- 1 \	Select P40 as TO1 pin.
P4FR ←	X X	- 1 )	Select P40 as TOT plit.
TRUN ←	X X 1	1 -	Start timer 1 counting.

(Note) X; Don't care -; No change

Figure 3.7 (9). Square Wave (50% Duty) Output Timing Chart

③ Making timer 1 count up by match signal from timer 0 comparator Set the 8-bit timer mode, and set the comparator output of timer 0 as the input clock to timer 1.

④ Output inversion with software

The value of timer flip-flop (timer F/F) can be inverted, independent of timer operation.

Writing "00" into TFFCR <FF1C1, 0> inverts the value of TFF1, and writing "00" into TFFCR <FF3C1, 0> inverts TFF3.

⑤ Initial setting of timer flip-flops (timer F/F)

The value of timer F/F can be initialized to "0" or "1", independent of timer operation. For example, write "10" in TFFCR <FF1C1, 0> to clear TFF1 to "0", while write "01" in TFFCR <FF3C1, 0> to set TFF1 to "1".

Note: The value of timer F/F and timer register cannot be read.

## (2) 16-bit timer mode

A 16-bit interval timer is configurated by using the pair of timer 0 and timer 1 or that of time 2 and timer 3. As the above two pairs operate in the same manner, only the case of combining timer 0 and timer 1 is discussed. To make a 16-bit interval timer by cascade connection timer 0 and timer 1, set timer 0/timer 1 mode register T01MOD <T01M1, 0> to "0, 1".

When set in 16-bit timer mode, the overflow output of timer 0 will become the input clock of timer 1, regardless of the set value of T01MOD <T1CLK1, 0>. Table 3.6 (2) shows the relation between the cycle of timer (interrupt) and the selection of input clock.

Interrupt cycle (@fc = 10MHz)	Resolution	Input clock		
0.8µs ~ 52.43ms	0.8µs	øT1 (8/fc)		
12.8µs ~ 838.86ms	12.8µs	øT16 (128/fc)		

# Table 3.7 (2) 16-bit Timer (Interrupt) Cycle and Input Clock

The lower 8 bits of the timer (interrupt) cycle are set by the timer register TREGO, and the upper 8 bits are set by TREG1. Note that TREGO always must be set first (Writing data into TREGO disables the comparator temporarily, which is restarted by writing data into TREG1).

Setting example: To generate interrupts INTT1 every 1 seconds at fc = 8 MHz, set the following values for timer register TREG0 and TREG1. When counting with input clock of  $\phi$ T16 (16 $\mu$ s @ 8MHz) 1sec  $\div$ 16 $\mu$ s = 62500 = F424H Therefore, set TREG1 = F4H and TREG0 = 24H, respectively. The comparator match signal is output from timer 0 each time the up-counter matches UC0, where the up-counter UC0 is not be cleared.

With the timer 1 comparator, the match detect signal is output at each comparator timing when up-counter UC1 and TREG1 values match. When the match detect signal is output simultaneously from both comparators of timer 0 and timer 1, the up-counters UC0 and UC1 are cleared to "0", and the interrupt INTT1 is generated. If inversion is enabled, the value of the timer flip-flop TFF1 is inverted

		Timer 0		Timer 1				
	INTTO	TO1	match	INTT1	TO1	match		
16 bit Timer Mode (Count-up Timer 1 by overflow of Timer 0	Interrupt is generated.	Can't output (Can't Output the matching with TREG0	TREG0 ( Continue counting when match )	Interrupt is generated.	Can output (Can't Output the matching with both TREG0 and TREG1	TREG 1 * 2 <sup>8</sup> + TREG0(16bit) (Cleared by matching with both registers)		
8 bit Timer Mode ( Count-up Timer 1 by matching of Timer 0	Interrupt is generated.	Can output (Timer 0 or Timer 1	TREGO (Clear when (match)	Interrupt is generated.	Can output (Timer 0 or Timer 1	TREG1* TREG0 (Multiplied Value (Cleared by matching		

Example: When TREG1 = 04H and TREG0 = 80H,

(3) 8-bit PPG (Programmable Pulse Generation) Mode

Square wave pulse can be generated at any frequency and duty by timer 1 and timer 3. The output pulse may be either low-active or high-active.

In this mode, timer 0 and timer 2 cannot be used. Timer 1 outputs pulse to TO1 pin (also used as P80), and timer 3 outputs pulse to TO3 pin (also used as P81).

# TMP90C848F

#### As an example, the case of timer 1 will be explained

#### below. (Timer 3 also functions in the same way.)

Figure 3.7 (12). Block Diagram of 8-bit PPG Mode

When the double buffer of TREG0 is enabled in this mode, the value of register buffer will be shifted in TREG0 each TREG1 matches UC0. Use of the double buffer makes easy the handling of low duty waves (when duty is varied).

Calculate the value to be set for timer registers.

should be: 1/50KHz = 20µs. Given  $\phi$ T1 = 1.0µs (@ 8MHz), 20µs ÷ 1.0µs =20 Consequently, to set the timer register 1 (TREG1) to

To obtain the frequency of 50kHz, the pulse cycle t

TREG1= 40 = 28H and then duty to 1/4, t x 1/4 = 20 $\mu$ s x 1/4 = 5 $\mu$ s

Therefore, set timer register 0 (TREG0) to TREG0 = 5 = 5AH.

MSB LSB ← 76543210 TRUN ← X X - - - - 0 0 Stop timer 0, and clear it to "0". T01MOD← 1 0 X X X X 0 1 Set the 8-bit PPG mode, and select  $\phi$ T1 as input clock. (Note) X; Don't care -; No change

# TMP90C848F

## (4) 8-bit PWM (Pulse Width Modulation) Mode

This mode is valid only for timer 1 and timer 3. In this mode, maximum two PWMs of 8-bit resolution (PWM1 and PWM3) can be output.

PWM pulse is output to TO1 pin (also used to P80) when using timer 1, and to TO3 pin (also used as P81) when using timer 3.

Timer 0 and timer 2 can also be used as 8-bit timer. As an example, the case of timer 1 will be explained below. (Timer 3 also operates in the same way.) Timer output is inverted when up-counter (UC0) matches the set value of timer register TREG0 or when 2n - 1 (n = 6, 7 or 8; specified by T01MOD < PWM01, 0>) counter overflow occurs. Up-counter UC1 is cleared when 2n - 1 counter overflow occurs.

To use this PWM mode, the following conditions must be satisfied.

(Set value of timer register) < (set overflow value of 2<sup>n</sup> - 1 counter)

(Set value of timer register)  $\neq 0$ 

#### Figure 3.7 (13). Block Diagram of 8-bit PWM Mode

In this mode, the value of register buffer will be shifted in TREG0 if 2<sup>n</sup> - 1 overflow is detected when the double buffer of TREG0 is enabled.

Use the double buffer makes easy the handling of small duty waves.

 Table 3.7 (4) Timer Mode Setting Register

# 3.8 Multi-Function 16-bit Timer/Event Counter (Timer 4)

The TMP90C845 contains one multifunctional 16-bit timer/ event counter with the following operating modes:

- 16-bit timer
- 16-bit event counter
- 16-bit programmable pulse generation (PPG)

- Frequency measurement
- Pulse width measurement
- Time differential measurement

Figure 3.8 (1) shows the block diagram of the 16-bit timer/  $\ensuremath{\mathsf{event}}$  counter.

Figure 3.8 (1). Block Diagram of 16-Bit Timer/Event Counter (Timer 4)

Timer/event counter consists of 16-bit up-counter, two 16-bit timer registers, two 16-bit capture registers, two comparators, register buffer, capture input controller, timer flip-flop, and the control circuit. Timer/event counter is controlled by 4 control registers T4MOD, T4FFCR, TRUN, and TRDC. TRUN register includes 8-bit timer controller. For TRUN and TRDC registers, see Figure 3.7 (7) and Figure 3.7 (8).

Figure 3.8 (2). 16-bit Timer/Event Counter (Timer 4) Controller/Mode Registers (1/2)

Figure 3.8 (3). 16-Bit Timer/Event Counter Timer Flip-flop Control Register

#### ① Up-counter (UC16)

UC16 is a 16-bit binary counter which counts up according to the input clock specified by T4MOD <T4CLK1, 0> register.

As the input clock, one of the internal clocks  $\sigma$ T1 (8fc),  $\sigma$ T4 (32fc), and  $\sigma$ TI6 (128fc) from 9-bit prescaler (also used as 8-bit timer), and external clock from TI4 pin (commonly used as P46/INT1 pin) can be selected. When reset, it will be initialized to <T4CLK1, 0> = 00 to select TI4 input mode. Counting, stop, or clearing of the counter is controlled by timer operation control register TRUN <T4RUN>.

Up-counter UC16 will be cleared to zero each time it coincides or matches the timer register TREG5. The

"clear enable/disable" is set by T4MOD <CLE>. If clearing is disabled, the counter operates as a freerunning counter.

② Timer Registers (TREG4 and TREG5)

These two 16-bit registers are used to set the value of counter. When the value of up-counter UC16 matches the set value of this timer register, the comparator match detect signal will be active.

Setting data for timer register (TREG4 and TREG5) is executed using 1-byte date road instruction twice for lower 8 bits and upper 8 bits in order.

TR	EG4	TREG5			
Upper 8 bits	Lower 8 bits	Upper 8 bits	Lower 8 bits		
FFE1H	FFEOH	FFE3H	FFE2H		

TREG4 timer register is of double buffer structure, which is paired with register buffer. TREG4 controls whether the double buffer should be enabled or disabled, using the timer register double buffer control register TRDC <TR4DE>: disable when <TR4DE> = 0, while enable when <TR4DE> = 1.

When the double buffer is enabled, the timing to transfer data from the register buffer to the timer register is at the match between the up-counter and TREG5.

When reset, it will be initialized to  $\langle TR4DE \rangle = 0$ , whereby the double buffer is disabled. To use the double buffer, write data in the timer register to set to  $\langle TR4DE \rangle = 1$  then write the following data in the register buffer. TREG4 and register buffer 4 are allocated to the same memory addresses FFE0H and FFE1H. When <TR4DE> = 0, same value will be written in both the TREG4 and register buffer 4. When <TR4DE> = 1, the value is written into only the register buffer 4.

③ Capture Register (CAP1 and CAP2)

These 16-bit registers are used to hold the values of the up-counter UC16. Data in the capture registers should be read by a 2-byte load instruction or two 1byte data load instruction, from the lower 8 bits followed by the upper 8 bits.

CA	AP1	CAP2		
Upper 8 bits	Lower 8 bits	Upper 8 bits	Lower 8 bits	
FFE1H	FFEOH	FFFE3H	FFE2H	

## ④ Capture Input Control Circuit

This circuit controls the timing to latch the value of up-counter UC16 into CAP1 and CAP2. The latch timing of capture register is controlled by register T4MOD <CAPM1, 0>.

• When T4MOD <CAPM1, 0 > = 0.0Capture function is disabled. Disable is the default on reset.

• When T4MOD <CAPM1, 0> = 01

Data is loaded to CAP1 at the rise edge of TI4 pin (commonly used as P83/INT1) input, while data is loaded to CAP2 at the TI5 pin (also used as P25/INT2) rising edge (Time difference measurement)

• When T4MOD <CAPM1, 0> = 10

Data is loaded to CAP1 at the rise edge of the Tl4 pin input while data is loaded to CAP2 at the fall edge. Only in this setting, interrupt INT1 occurs at the falling edge. (Pulse width measurement)

• When T4MOD <CAP1, 0> = 11

Data is loaded to CAP1 at the rise edge of timer flip-flop TFF1, while to CAP2 at the fall edge. (Frequency measurement)

Besides, the value of up-counter can be loaded to capture registers by software. Whenever "0" is written in T4MOD <CAPIN>, the current value of up-counter will be loaded to capture register CAP1. It is necessary to keep the prescaler in RUN mode (TRUN <PRUN>to be "1").

(5) Comparator (CP4 and CP5)

These are 16-bit comparators which compare the upcounter UC16 value with the set value of TREG4 or TREG5 to detect the match. When a match is detected, the comparators generate an interrupt INTT4 and INTT5, respectively. The up-counter UC16 is cleared only when UC16 matches TREG5. (The clearing of upcounter UC16 can be disabled by setting T4MOD <CLE> = 0).

© Timer Flip-flop (TFF4)

This flip-flop is inverted by the match detect signal from the comparators (CP4 and CP5) and the latch signal to the capture registers (CAP1 and CAP2). Disable/enable the inversion can be set for each element by T4FFCR <CAP2T4, CAP1T4, EQ5T4, EQ4T4>. TFF4 will be inverted when "00" is written in T4FFCR < TFF4C1, 0>. Also it is set to "1" when "10" is written, and cleared to "0" when "10" is written. The value of TFF4 can be output to the timer output pin TO4 (commonly used as P85).

(1) 16-bit Timer Mode

In this example, the interval time is set in the timer register TREG5 to generate the interrupt INTT5.

TRUN ←	X X - 0	Stop timer 4.
INTEL ←	0 - 1	Enable INTT5 and disable INTT4.
T4FFCR←	X X 0 0 0 0 1 1	Disable trigger.
T4MOD ←	X X 1 0 0 1 * * (**=01,10,11)	Select internal clock for input and disable the capture function.
TREG5 ←	**** **** ****	Set the interval time (16 bits).
TRUN ←	X X 1 1	Start timer 4.

(Note) X; Don't care -; No change

#### (2) 16-bit Event Counter Mode

In timer mode as described in above (1), the timer can be used as an event counter by selecting the external clock (TI4 pin input) as the input clock. To read the value of the counter, first perform "software capture" once and read the captured value.

The counter counts at the rise edge of TI4 pin input. TI4 pin can also be used as P83/INT1.

TRUN	٠	X	X	-	0	-	-	-	-	Stop timer 4.
P8FR	٠	X	X	-	-	٠	X	-	-	* = 0 :TI4 input pulse is square wave

INTEL	٠	0	0	1	-	-	-	-	-	Enable INTT5, while disables INTT4 and INT1.
T4FFCF	₹⊷	X	X	0	0	0	0	1	1	Disable trigger.
T4MOD	٠	X	X	1	0	0	1	0	0	Select TI4 as the input clock.
TREG5	٠	••	•••		***	••	**	***	* ****	Set the number of counts (16 bits).
_TURN	+	-	-	1	1	-	-	-	-	Start timer 4.
(Note)	(Note) When used as an event counter, set the prescaler in RUN mode.				er, set the prescaler in RUN mode.					

(3) 16-bit Programmable Pulse Generation (PPG) Mode

The PPG mode is entered by inversion of the timer flipflop TFF4 that is to be enabled by match of the up-counter UC16 with the timer register TREG 4 or 5 and to be output to TO4 (also used as P85). In this mode, the following conditions must be satisfied. (Set value of TREG4) < (Set value of TREG5)

```
TRUN ← X X - 0 - - - -
                                     Stop timer 4.
TREG4 ←
                                     Set the duty.
TREG5 ← ****
                     **** ****
               ****
                                     Set the cycle.
T4FFCR← X X 0 0 1 1 0 0
                                     Set the TFF4 inversion to be effected by match with TREG4 or
                                     TREG5. Initialize TFF4 to "0".
T4MOD ← X X 1 0 0 1 * *
                                     Select the internal clock for the input, and disable the capture
                   (**=01,10,11)
                                     function.
P8CR ←
         X X 1
                  _
                      - -
                   (**=00,01,10)
                                     Assign P85 as TO4.
P8FR ← X X 1 - - X - -
TRUN ← X X 1 1 - - - -
                                     Start timer 4.
(Note) X; Don't care
                           -; No change
  Match with TREG4
  (interrupt INTT4)
  Match with TREG5
  (interrupt INTT5)
  TO4 pin
```
When the double buffer of TREG4 is enabled in this mode, the value of register buffer 4 will be shifted in TREG4 at match with TREG5. This feature makes easy the handling of low duty waves (when duty rate is varied).

(4) Application examples of capture function

The loading of up-counter (UC16) values into the capture registers CAP1 and CAP2, the timer flip-flop TFF4 inversion due to the match detection by comparators CP4 and CP5, and the output of the TFF4 status to TO4 pin can be enabled or disabled. Combined with interrupt function, they can be applied in many ways, for example:

- ① One-shot pulse output from external trigger pulse
- ② Frequency measurement
- ③ Pulse width measurement
- ④ Time difference measurement

① One-shot pulse output from external trigger pulse

Set the up-counter UC16 in free-running mode with the internal input clock, input the external trigger pulse from TI4 pin, and load the value of up-counter into the capture register CAP1 at the rising edge of TI4 pin. Then set to T4MOD <CAPM1, 0 > = 01.

When the interrupt INT1 is generated at the rising edge of TI4 input, set the CAP1 value (c) plus a delay time (d) to TREG4 (= c + d). and set the above set value (c + d) pulse a one shot pulse width (p) the TREG5 (= c + d + p). When the interrupt INT1 occurs the T4FFCR (BIT 2 ~ 5) register should be set that the TFF4 inversion is enabled only when the up-counter value matches TREG4 or 5. When interrupt INTT5 occurs, this inversion will be diabled.

Figure 3.8 (4). One-Shot Output (with Delay)

Setting example: To output 2ms one-shot pulse with a

3ms delay to the external trigger pulse to TI4 pin.

Main setting Keep counting (Free-runnig) Count with  $\phi$ T1. T4MOD ← X X 1 0 1 0 0 1 Load the up-counter value into CAP1 at the rise edge T4FFCR← X X 0 0 0 0 0 of T14 pin input. Clear TFF4 to zero. Disable TFF4 inversion. P8CR ← X X 1 - 0 - - -(\*\*=00,01,10)Select P85 as the TO4 pin. P8FR ← X X 1 - - X - -INTEL ← 0 1 0 - - - - -Enable INT1, and disable INTT4 and INTT5. TRUN ← X X 1 1 - - - -Start timer 4.

Setting of INT1

TREG4 ←	CAP1+3ms∕¢T1	
TREG5 ←	TREG4+2ms/∳T1	
T4FFCR←	X X 1 1	
	└ <u></u>	Enable TFF4 inversion when the up-counter value
		matches TREG4 or 5.
LINTEL ←	1	Enable INTT5.

Setting of INT5	
T4FFCR← X X 0 0	Disable TFF4 inversion when the up-counter value matches TREG4 or 5.
_INTEL ← 0	Disable INTT5.
(Note) X; Don't care -; No cha	nge

When delay time is unnecessary, invert timer flip-flop TFF4 when the up-counter value is loaded into capture register 1 (CAP1), and set the CAP1 value (c) plus the one-shot pulse width (p) to TREG5 when the interrupt INT1 occurs. The TFF4 inversion should be enabled before the up-counter (UC16) value matches TREG5, and disabled when generating the interrupt INTT5.

Figure 3.8 (5). One-Shot Pulse Output (without Delay)

<sup>②</sup> Frequency measurement

The frequency of the external clock can be measured in this mode. The clock is input through the Tl4 pin, and its frequency is measured by using the 8-bit timers (Timer 0 and Timer 1) and the 16-bit timer/event counter (Timer4). The TI4 pin input should be selected for the input clock of Timer 4. The value of the up-counter is loaded into the capture register CAP1 at the rise edge of the timer flip-flop TFF1 of 8-bit timers (Timer 0 and Timer 1), and into CAP2 at its fall edge.

The frequency is calculated by the difference between the loaded values CAP1 and CAP2 when the interrupt (INTT0 or INTT1) is generated by either 8-bit timer.

For example, if the value for the level "1" width of TFF1 of the 8-bit timer is set to 0.5 sec. and the difference between CAP1 and CAP2 is 100, the frequency will be 100/0.5 [s] - 200 [Hz].

3 Pulse width measurement

This mode allows to measure the "H" level width of an external pulse. While keeping the 16-bit timer/event counter counting (free-running) with the internal clock input, the external pulse is input through the Tl4 pin.

Then the capture function is used to load the UC16 values into CAP1 and CAP2 at the rising edge and falling edge of the external trigger pulse respectively. The interrupt INT1 occurs at the falling edge of TI4. The pulse width is obtained from the difference between the values of CAP1 and CAP2 and the internal clock cycle.

For example, if the internal clock is 8.0 microseconds and the difference between CAP1 and CAP2 is 100, the pulse width will be  $100 \times 0.8 = 80$  microseconds.

#### Figure 3.8 (7) Pulse Width Measurement

Note: Only in this pulse width measuring mode (T4MOD <CAPM1, 0> = 10), external interrupt INT1 occurs at the falling edge of TI4 pin input. In other modes, it occurs at the rising edge.

The width of "L" level can be measured from the difference between the first C2 and the second C1 at the second INT1 interrupt.

④ Time difference measurement

This mode is used to measure the difference in time between the rising edges of external pulses input through TI4 and TI5.

Keep the 16-bit timer/event counter (Timer 4) counting

(free-running) with the internal clock, and load the UC16 value into CAP1 at the rising edge of the input pulse to TI4. Then the interrupt INT1 is generated. Similarly, the UC16 value is loaded into CAP2 at the rising edge of the input pulse to TI5, generating the interrupt INT2.

The time difference between these pulses can be obtained from the difference between the time counts at which loading the up-counter value into CAP1 and CAP2 has been done.

#### **3.9 Serial Channel**

The TMP90C848F contains a serial I/O channel for full duplex asynchronous transmission (UART) as well as for I/O

extension.

The serial channel has the following operating modes:

 Asynchronous transmission (UART) mode
 Mode 1: 7-bit data Mode 2: 8-bit data Mode 3: 9-bit data

The mode 1 and mode 2, a parity bit can be added. Mode 3 has wake-up function for making the master controller start slave controllers serial link (multi-controller system).

Figure 3.9 (1) shows the data format (for one frame) in each mode.

Figure 3.9 (1). Data Formats

The serial channel has a buffer register for transmitting and receiving operations, in order to temporarily store transmitted or received data, so that transmitting and receiving operations can be done independently (full duplex).

The receiving buffer register is of a double buffer structure to prevent the occurrence of overrun error and provides one frame of margin before CPU reads the received data. Namely, the one buffer stores the already received data while the other buffer receives the next frame data.

In the UART mode, a check function is added not to start the receiving operation by error start bits due to noise. The channel starts receiving data only when the start bit is detected to be normal at least twice in three samplings. When the transmission buffer becomes empty and requests the CPU to send the next transmission data or when data is stored in the transmission buffer and the CPU is requested to read the data, INTTX or INTRX interrupt occurs. Besides, if an overrun error, parity error, or framing error occurs during receiving operation, flag SCCR <OERR, PERR, FERR> will be set.

The serial channel includes a special baud rate generator, which can set any baud rate by dividing the frequency of 4 clocks (ØT0, ØT2, ØT8, and ØT32) from the internal prescaler (shared by 8-bit/16-bit timer) by the value 2 to 16.

#### **3.9.1 Control Registers**

The serial channel is controlled by 4 control registers SCMOD,

SCCR, TRUN, BRGCR, and P3FR. Transmitted and received data are stored into SCBUF.

Transmission data bit 8

Figure 3.9 (2). Serial Channel Mode Register (SCMOD)

Note: As all error flags are cleared after reading, do not test only a single bit with a bit-testing instruction.

# 3.9.2 Configuration

Figure 3.9 (7) is a block diagram of the serial channel.

Figure 3.9 (7). Block Diagram of the Serial Channel

#### ① Baud-rate generator

Baud-rate generator comprises a circuit that generates transmission and receiving to determine the transfer rate of the serial channel.

The input clock to the baud-rate generator  $\sigma$ T0(fc/4),  $\sigma$ T2 (fc/16),  $\sigma$ T8 (fc/64), or  $\sigma$ T32 (fc/256) is generated by the 9-bit prescaler which is shared by the timers. One of these input clocks is selected by the baud rate generator control register BRGCR <BG1, 0>.

The baud rate generator includes a 4-bit frequency divider, which divides frequency by 2 to 16 values to determine the transfer rate.

How to calculate a transfer rate when the baud rate generator is used is explained below.

Transfer rate =	Input clock of baud rate generator	$\div 16$
Transfer Tate -	Frequency divisor of baud rate generator	÷ 10

The relation between the input clock and the source clock (fc) is as follows.

Accordingly, when source clock fc is 9.8304MHz, input clock is øT2 (fc/16), and frequency divisor is 4, the transfer rate in UART mode becomes as follows:

Transfer rate =  $\frac{fc/16}{5} \div 16$ 

 $= 9.8304 \times 10^{6}/16/4/16 = 9600$  (bps)

Table 3.9 (1) shows shows an example of the transfer rate UART mode.

Also with 8-bit timer 2, the serial channel can get a transfer rate. Table 3.9 (2) shows an example of baud rate using timer 2.

#### Table 3.9 (1) Selection of Baud Rate (1) (When Baud Rate Generator is Used) (Units [Kbps]

	Input clock	øT0	øT2	øT8	øT32	
fc	Frequency divisor	(fc/4)	(fc/16)	(fc/64)	(fc/256)	
9.8304MHz	2	76.800	19.200	4.800	1.200	
-	4	38.400	9.600	2.400	0.600	
-	8	19.200	4.800	1.200	0.300	
-	0	9.600	2.400	0.600	0.150	

# Table 3.9 (2) Selection of Transfer Rate (2)(When Timer 2 (Input Clock T1) is Used)

fc	9.8304	8	6.144
TREG2	MHz	MHz	MHz
1H	76.8	62.5	48
2H	38.4	31.25	24
ЗН	-	-	16
4H	19.2	-	12
5H	-	-	9.6
8H	9.6	-	6
AH	-	-	4.8
10H	4.8	-	3
14H	-	_	2.4

How to calculate the baud rate (when timer 2 is used):

Baud rate =

 $\frac{1}{\text{TREG2}} \times \frac{1}{16} \times (\text{Input clock of timer 2})$ 

Input CLK of timer 2

<sup>(2)</sup> Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

According to the setting of SCMOD <SC1, 0>, the above baud rate generator clock, internal clock ø1(fc/2) (312.5Kbaud at 10MHz), or the match detect signal from timer 2 will be selected to generate the basic clock SIOCK.

#### ③ Receiving counter

The receiving counter is a 4-bit binary counter used in asynchronous communication (UART) mode and counts up by SIOCLK clock. 16 pulses of SIOCLK are used for receiving 1 bit of data, and the data bit is sampled three times at the 7th, 8th and 9th clock. With the three samples, the received data is evaluated by the rule of majority.

For example, if the sample data bits is "1", "0" and "1" at 7th, 8th and 9th clock, respectively, the received data is evaluated as "1". The sampled data "0", "0" and "1" is evaluated the received data is "0".

#### ④ Receiving control

The receiving control has a circuit for detecting the start bit by the rule of majority. When two or more "0" are detected during three samples, it is recognized as normal start bit and the receiving operation is started. Data being received are also evaluated by the rule of majority.

#### ⑤ Receiving buffer

To prevent overrun from occurring, the receiving buffer has a double structure. Received data are stored one bit by on bit in the receiving buffer 1 (shift register type). When 7 or 8 bits of data is stored in the receiving buffer 1, the stored data are transferred to another receiving buffer 2 (SCBUF), generating an interrupt INTRX. The CPU reads receive buffer 2 (SCBUF). Even before the CPU reads receive buffer 2 (SCBUF), the received data can be stored in the receiving buffer 1. However, unless the receiving buffer 2 (SCBUF) is read before all bits of the next data received by the receiving buffer 1, an overrun error occurs. If an overrun error occurs, the contents of the receiving buffer 1 will be lost, although the contents of the receiving buffer 2 and SCCR <RB8> is still preserved.

When 9-bit UART, wake-up function of the slave controllers is enabled by setting SCMOD <WU> to "1" and interrupt INTRX occurs only SCCR <RB8> is set to "1".

The parity bit added in 8-bit UART mode and the mosy significant bit (MSB) in 9-bit UART mode are stored in SCCR <RB8>.

<sup>®</sup> Transmission counter

Transmission counter is a 4-bit binary coutner which is used in asynchronous communication (UART) mode and, like the receiving counter, counts by SIOCLK clock, generating TXDCLK is generated every 16 clock pulses.

#### $\ensuremath{\mathcal{O}}$ Transmission controller

When transmission data are written in the transmission buffer sent from the CPU, transmission starts at the rising edge of the next TxDCLK, generating a transmission shift clock TxDSFT.

#### Transmission buffer

Transmission buffer SCBUF shifts out and sends the transmission data written by the CPU from the least signicant bit (LSB) in order, using transmission shift clock TxDSFT which is generated by the transmission control. When all bits are shifted out, the transmission buffer becomes empty and generates INTTX interrupt.

#### Parity control circuit

When serial channel control register SCCR <PE> is set to "1", it is possible to transmit and receive data with parity. However, parity can be added only in 7-bit UART or 8-bit UART mode. When SCCR <EVEN> register, even (odd) parity can be selected.

For transmission mode, parity is automatically generated

according to the data written into the transmission buffer SCBUF, and data are transmitted after being stored in SCBUF <TB7>when in 7-bit UART mode while in SCMOD <TB8> when in 8-bit UART mode. <PE> and <EVEN> must be set before transmission data are written in the transmission buffer.

For receiving, data are shifted in the receiving buffer 1 and parity is added after the data are transferred in the receiving buffer 2 (SCBUF), and then compared with <RB7> of SCBUF when in 7-bit UART mode and with SCCR <RB8> when in 8-bit UART mode. If they are not equal, a parity error occurs, and SCCR <PERR> flag is set.

#### 1 Error flag

Three error flags are provided to increase the reliability of receiving data.

#### 1. Overrun error (SCCR <OERR>)

If all bits of the next data are received in receiving buffer 1 while valid data are still stored in receiving buffer 2 (SCBUF), an overrun error will occur. 2. Parity error (SCCR < PERR>)

The parity generated for the data shifted in receiving buffer 2 (SCBUF) is compared with the parity bit received from the RxD pin. If they are not equal, a parity error occurs. 3) Framing error (SCCR <FERR>)

The stop bit of received data is sampled three times around the center. If the majority is "0", a framing error occurs.

#### ① Generating Timing

#### Receiving

Mode	9 Bit	8 Bit + Parity	8 bit, 7 Bit + Parity, 7 Bit
Interrupt timing	Center of last bit	Center of last bit (Parity Bit)	Center of stop bit
Framing error timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity error timing	Center of last bit (Bit 8)	Center of last bit (Parity Bit)	Center of stop bit
Over-run error timing	Center of last bit (Bit 8)	Center of last bit (Parity Bit)	Center of stop bit

#### Transmitting

Mode	9 Bit	8 Bit + Parity	8 Bit, 7 Bit + Parity, 7 Bit
Interrupt timing	Just before last bit is transmitted	$\leftarrow$	←

# (1) Mode 1 (7-bit UART Mode)

The 7-bit mode can be set by setting serial channel mode register SCMOD <SM1, 0> to "01".

In this mode, a parity bit can be added, and the addition of a parity bit can be enabled or disabled by serial channel control register. SCCR <PE>, and even parity or odd parity is selected by SCCR <EVEN> when <PE> is set to "1" (enable).

Setting example: When transmitting data with the following format, the control registers should be set as described below.

← Transfer direction (transfer rate: 2400 bps at fc=9.8304 MHz)

		7	6	5	4	3	2	1	0	
P3FR	←	-	Х	χ	Х	Х	1	-	Х	Select P32 as the TxD pin.
SCMOD	←	Х	0	-	Х	0	1	0	1	Set 7-bit UART mode.
SCCR	←	Х	1	1	Х	Х	Х	Х	Х	Add an even parity.
BRGCR	←	0	Х	1	0	0	1	0	0	Set transfer rate at 2400 bps.
TRUN	←	Х	Х	1	-	-	-	-	-	Start the prescaler for the baud rate generator.
INTEL	←	-	-	-	-	-	1	-	-	Enable INTTX interrupt.
SCBUF	←	*	*	*	*	*	*	*	*	Set data for transmission.

(Note) X; Don't care -; No change

(2) Mode 2 (8-bit UART Mode)

The 8-bit UART mode can be specified by setting SCMOD <SM1, 0> to "10". In this mode, parity bit can be added. the addition of a parity bit is enabled or disabled by SCCR <PE>, and even parity or odd parity

Г

is selected by SCCR <EVEN> when <PE> is set to "1" (enable).

Setting example: When receiving data with the following format, the control register should be set as described below.

Direction of transmission (transmission rate: 9600 bps @ fc = 9.8304 MHz)

Main setting

Γ		7	6	5	4	3	2	1	0	
SCMOD	←	-	0	1	Х	1	0	0	1	Enable receiving in 8-bit UART mode.
SCCR	←	Х	0	1	Х	Х	Х	Х	Х	Add an odd parity.
BRGCR	٠	0	Х	0	1	0	1	0	0	Set transfer rate at 9600 bps.
TRUN	←	Х	Х	1	-	-		-	-	Start the prescaler for the baud rate generator.
INTEL	←	-	-	-	-	1	-	-	-	Enable INTRX interrupt.
_										

INTRX processing

```
Acc ← SCCR AND 00000011 Check for error.

if Acc ≠ 0 then error

Acc ← SCBUF Read the received data.

(Note) X; don't care -; no change
```

#### (3) Mode 3 (9-Bit UART Mode)

The 9-bit UART mode can be specified by setting serial channel mode register SCMOD0 <SM01, 00> to "11". In this mode, a parity bit cannot be added. For transmission, the MSB (9th) bit is written to SCMOD <TB8>, while in receiving it is stored in SCCR <RB8>. For writing and reading the buffer, the MSB is read or written first then SCBUF.

#### Wake-up function

In 9-bit UART mode, the wake-up function of the slave controllers is enabled by the setting SCMOD <WU> to "1". The interrupt INTRX is generated when SCCR <RB8> = 1.

Note :  $\ensuremath{\operatorname{TxD}}$  pin of the slave controllers must be in open drain output mode.

#### Figure 3.9 (13). Serial Link Using Wake-up Function

# Protocol

- ① Select the 9-bit UART mode for the master and slave controllers.
- ② Set SCMOD <WU> bit of each slave controller to "1" to enable receiving.
- ③ The master controller transmits one frame data including the 8-bit select code for the slave controllers. The MSB (bit 8) SCMOD <TB8> is set to "1".

- ④ Each slave controller receives the above frame, and clears the WU bit to "0" if the above select code matches its own select code.
- (5) The master controller transmits data to the specified slave controller whose SCMOD <WU> bit is cleared to "0". The MSB (bit 8) SCMOD <TB8> is cleared to "0".

(e) The other slave controllers (with the SCMOD <WU> bit remaining at "1") ignore the receiving data because their MSBs (bit 8 or SCCR <RB8>) are set to "0" is disable the interrupt INTRX.

When the WU bit is cleared to "0", the interrupt INTRX occurs, so that the slave controller can read the receiving data.

The slave controllers (WU = 0) transmit data to the master controller, and it is possible to indicate the end of data receiving to the master controller by this transmission.

Setting example: To link two slave controllers serially with the master controller, and use the internal clock ø1 (fc/2) as the transfer clock.

```

# 3.10 8-Bit Half-Flash A/D Converter

The TMP90C848 has an 8-bit high-speed, half-flash A/D converter with 16-channel analog input. The features are as follows.

- 8-bit half-flash A/D converter with 16-channels analog input pins
- Minimum sampling rate: 4 states (800ns @fc =10MHz)
- Software start (register write) trigger with single or repeat conversion mode

The A/D converter block diagram is shown in Figure 3.10 (1).

Figure 3.10 (1). A/D Converter Block Diagram

# 3.10.1 Basic Operation of the Half-Flash A/D Converter

This is a two-time conversion type A/D converter that converts

the upper four bits and lower four bits separately. The function outline is shown in Figure 3.8 (2).

When the A/D converter start signal (ADS) is input, the analog input voltage in T1 is sampled by the A/D converter for the upper four bits and the A channel for the lower four bits. The A/D converter for the upper four bits compares the output voltage from the internal ladder resistance with input voltage in T2, and outputs the conversion results of the upper four bits. The A channel A/D converter for the lower four bits compares in T4 in the same way that held the voltage in T1. The 8-bit conversion results can be obtained in T5.

The A/D converter for the lower four bits has two channels (A and B). The next analog input voltage in T3 is sampled by the A/D converter for the upper four bits and B channel A/D converter for the lower four bits.

This type of processing enables the high-speed A/D conversion with a minimum sampling rate of 4 states (800ns @ 10MHz).

# 3.10.2 Operation

(1) A/D converter start operation

The A/D converter starts by writing "1" to ADMOD <ADS>. <ADS> is always read as "0".

(2) A/D converter repeat specification

In the repeat mode, the A/D converter starts automatically after completion each conversion.

The A/D conversion in repeat mode is started by writing "1" to both <ADS> and <ADRPT>.

To end the repeat mode operation, write "0" to <RPT>. The repeat mode will end when the current conversion is completed.

Read the A/D conversion result storage register ADREG in the repeat mode since it contains the newest conversion data. The repeat mode operation timing is shown in Figure 3.10 (3).

A/D converter becomes the one-time conversion mode.

<ADRPT> is cleared to "0" by resetting: therefore, the

Figure 3.10 (3). Repeat Mode Operation Timing

(4) Analog input channel

Before starting the A/D conversion, select one of the 16 analog input channels (AN0  $\sim$  AN15) with ADMOD <ADCH>.

ANO (P30) is set as the analog input pin by clearing <ADCH> to "0" by reset. To use AN1 (P31), write "1" to <ADCH>.

The pin which is not used as an analog input can be used as an ordinary input port.

#### 3.10.3 Control Register

Figure 3.10 (5). A/D Converter Related Register

#### 3.10.4 Analog Reference Voltage

The VREF pin is the High A/D converter analog reference voltage input pin. The A Vcc and A Dss pins are used as the A/D converter power supply.

The VREF pin is variable ( $3.5 \le VREF \le Vcc$ ); however, when the VREF voltage is below 5V, the conversion error for the LSB tends to increase. Refer to "4.3 A/D Converter Electrical Characteristics" for the specifications.

Program Example

To A/D convert the analog input voltage of the AN1 (P51) pin in the repeat mode:

ADMOD←1 X 100001 Starts conversion with channel 1 in the repeat mode.

(Note) X; Don't care

#### 3.11 Watchdog Timers (Runaway Detecting Timer)

When CPU operation malfunctions (runaway) usually caused by noise or other disturbances, the watchdog timer (WDT) detects the situation and returns it to a normal state. When the WDT detects a malfunction, a non-maskable interrupt or a hardware reset is generated.

#### 3.11.1 Configuration

Figure 3.11 (1) shows the block diagram of the watchdog timer (WDT).

The watchdog timer consists of: a 20-stage binary counter which uses  $\phi 1$  (@fc/2) as the input clock, a selector, which slects one of four outputs sent from the binary counter, a flip-flop, for enable/disable control, and two control registers.

Figure 3.11 (1). Block Diagram of Watchdog Timer

#### 3.11.2 Control Registers

The watchdog timer (WDT) is controlled by two control registers WDMOD, WDCR, and CLKMOD.

- (1) Watchdog Timer Mode Register (WDMOD)
  - ① Setting a watchdog timer detection period (WDTP)

A 2-bit register is used to set the watchdog timer interrupt time or hardware reset time in order to detect a runaway. The WDTP is initialized to "00" when reset, and therefore  $2^{16}$ /fc is set. (The number of states is approx. 32,768 [state].)

 Watchdog Timer Enable/Disable Control Register (WDTE) When reset WDTE is initialized to "1", which sets the watchdog timer to disable.

To enable the watchdog timer, it is necessary to clear this bit to "0".

The mode cannot be switched back from enable to disable.

3 Setting Watchdog Timer Mode

When reset, the WDRESE is initialized to "1", which sets the watchdog timer to interrupt mode. When the WDRESE is reset to "0", the watchdog timer initiates a hardware reset. Once the hardware reset mode is set, the mode cannot be changed to interrupt mode. (Interrupt mode is set only by reset.)

(Note) The watchdog timer cannot be reset from enable to disable.

Figure 3.11 (2). Watchdog Timer Mode Register

(2) Watchdog Timer Control Register (WDCR)

This register is used to disable the watchdog timer function and clear the binary counter.

• Disable control

The watchdog timer cannot be reset from enable to disable.

• Enable control

Set the WDMOD <WDTE> to "0".

• Clear control of binary counter

The binary counter can be cleared and resumes counting by writing the clear code (4EH) in the WDCR register.

WDCR ← 0 1 0 0 1 1 1 0 Write a clear code (4EH)

Figure 3.11 (3). Watchdog Timer Control Register

# 3.11.3 Operation

The watchdog timer generates an interrupt INTWD or a hardware reset after a specified detection timewhich is set with the WDMOD <WDTP1,0> register, and software (instruction) clears the watchdog timer binary counter to zero before the interrupt INTWD or the hardware reset occurs. If the CPU malfunctions (runaway) due to noise or other reasons and does not execute an instruction to clear the binary counter, the binary counter overflows. This results in an interrupt INTWD or hardware reset execution. The CPU is notified of malfunction (runaway) by the interrupt INTWD and executes the anti-malfunction (runaway) program to return to normal operation.

The watchdog timer does not operate after a reset is released. The watchdog a timer starts by writing "0" to the WDMOD <WDTE>, and does not change to disable afterward.

The watchdog timer stops its operation in the STOP and IDLE1 modes. After STOP is released, the watchdog timer resumes its operation as soon as the warm-up period is finished.

The watchdog timer operates in RUN mode.

Example : ① Clear the binary counter.

WDCR ← 0 1 0 0 1 1 1 0 Write a clear code (4EH)

2 Set the watchdog timer detection period to  $2^{18}/\text{fc.}$ 

 $\mathsf{WDMOD} \leftarrow \mathsf{1} \ \mathsf{0} \ \mathsf{1} \ \mathsf{-} \ \mathsf{-} \ \mathsf{X} \ \mathsf{X}$ 

(3) Set STOP mode. (Warm-up time :  $2^{16}$ /fc) (Except that HALTD is not set to "1".)

WDMOD  $\leftarrow$  - - - 1 0 1 X X Execute the HALT instruction.

Set STOP mode. Set standby mode.

(Note) Since the watchdog timer is also used as a warm-up timer, the watchdog timer is cleared when switching from low-speed to high-speed clock mode, or when releasing standby mode.

# 3.12 8-Bit High-speed PWM

The TMP90C848F has an internal 8-channel high-speed PWM. The 8-channel high-speed PWM can generated different waves from a data register of each channel by writing data to the register. The high-speed PWM operates only in high-speed clock mode, not in low-speed clock mode. Figure 3.12 (1) shows the block diagram of the high-speed PWM.

Each channel of the HPWM consists of an 8-bit data register, 8-bit comparator and additionally, a pulse generation circuit. Also, there is an 8-bit up-counter which is used commonly by all channels. The clock input of the up-counter is sent by the high-speed clock (X1).

Figure 3.12 (1). Block Diagram for High-Speed PWM

HPWM data register

3

1

0

4

Figure 3.12 (2). Registers of High-Speed PWM

# 3.12.1 Operation

The high-speed PWM is controlled by the controlled register (HPWMCR), output enable register (HPWMER), and data register (HPWMR0 - 7). To write data to the above registers, set the HPWMCR < PWCCR> to "0", which is enable mode. When the HPWMCR <PWCCR> is set to "1", these registers are in reset mode, which sets up the high-speed PWM for a software reset.

#### (1)**Operation Mode**

The high-speed PWM has three operation modes.

- 8-bit mode: (T = 2<sup>8</sup> x clock cycle, f = \*80KHz)
  7-bit mode: (T = 2<sup>7</sup> x clock cycle, f = \*160KHz)
- 6-bit mode: (T =  $2^6$  x clock cycle, f = \*320KHz)

(Note)\* indicates the value when the high-speed clock (x1) operates at 20MHz.

Operation mode is set by HPWMCR < PWMMOD0, 1>. Operation mode applies commonly to all channels. Two modes cannot be used at any given time.

1 8-bit mode

8-bit mode generates a pulse with 12.8µs cycle at a frequency of approximately 80KHz (x1 = 20MHz).

The minimum pulse width is 50ns (data "1") and the maximum pulse width is 12.0µs (data "F0").

Pulse width = 8-bit data  $\times$  50ns

A wave cycle example is shown below. (The value is when x1 = 20MHz.)

#### 2 7-bit mode

frequency of approximately 160KHz (x1 = 20MHz).

The 7-bit mode generates a pulse with  $6.4\mu s$  cycle at a

7-bit mode has for a cycle  $(2^7 \times 5ns^*/cycle)$  and 1 bit for a 25ns resolution (1/2 cycle of high-speed clock (x1)). When the lower 1 bit is "1", the additional 25ns pulse is output.

The minimum pulse width is 25ns (data "1") and the maximum pulse width is  $6.025\mu s$  (data "F1").

Pulse width = (Upper 7-bit data x 50ns) + (Lower 1-bit data x25ns)

A wave cycle example is shown below. (The value is when x1 = 20MHz.)

3 6-bit mode

6-bit mode generates a pulse with  $3.2\mu s$  cycle at a frequency of approximately 320 KHz (x1 = 20 MHz).

6-bit mode has 6 bits for a cycle (2<sup>6</sup> x 50ns \*/cycle) and 2 bits for a 12.5ns resolution. Although the actual resolution every other cycle is 25ns, a 12.5ns resolution is simulated in the following way: The first cycle outputs a 25ns pulse, which is averaged with the second cycle of 0ns. The pattern alternates continually and averages to a 12.5ns (data "1") and the maximum equivalent pulse width is 3.0375µs (data "F3").

Pulse width = (Upper 6-bit data x 50ns + (\*Lower 2-bit data) Equivalent time added for lower 2-bit data is shown below.

2-bit data	Equivalent time added
00	Ons
01	12.5ns
10	25.0ns
11	37.5ns

A wave cycle example is shown below. (The value is when x1 = 20MHz.)

(2) Output port setting

The high-speed PWM is used together with P2 and can output PWM waves by setting P2FR <P20F  $\sim$  P27F> to "1">.

(3) Output enable bit register setting

To output PWM waves, the output enable bit register HPWMER <HPE0  $\sim$  7> needs to be set to "1". (This register is cleared to "0" after reset.)

(4) Output data setting

Output data is set by writing to HPWMR0 ~ 7 (FFF0H ~ FFF7H).

Example: To output  $4.525\mu$ s wave with HPWM0 in 7bit mode with a high-speed clock (x 1) = 20MHz:

When the resolution in 7-bit mode is 25ns, a 4.525 $\mu$ s pulse is output by setting the following to HPWM0: 4.525 $\mu$ s ÷ 25ns =181 = B5H

	MSB						LSB	
	76	5	4	3	2	1	0	
P2FR		-	-	-	-	-	1	Set P20 to HPWM.
HPWMCR	ΧХ	Х	Х	Х	0	-	-	Specify setting enable mode.
HPWMCR	ΧХ	Х	Х	Х	0	0	1	Set 7-bit mode.
HPWMR0	1 0	1	1	0	1	0	1	Write "B5H".
HPWMER		-	-	-	-	-	1	Switch HPWM output to enable.

(Note)x; don't care -: no change
