description

The TMS28F400BZx is a 524288 by 8-bit/262144 by 16-bit (4194304-bit), boot-block flash memory that can be electrically block-erased and reprogrammed. The TMS28F400BZx is organized in a blocked architecture consisting of one 16K-byte protected boot block, two 8K-byte parameter blocks, one 96K-byte main block, and three 128K-byte main blocks. The device can be ordered with either a top or bottom boot-block configuration. Operation as a 512K-byte (8-bit) or a 256K-word (16-bit) organization is user-definable.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

BOOT-BLOCK FLASH MEMORIES

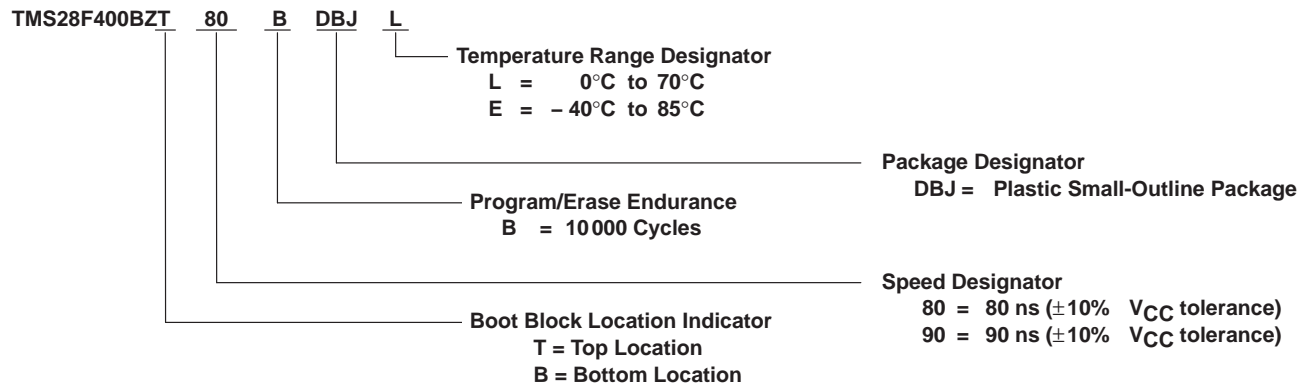

SMJS400E – JUNE 1994 – REVISED JANUARY 1998

description (continued)

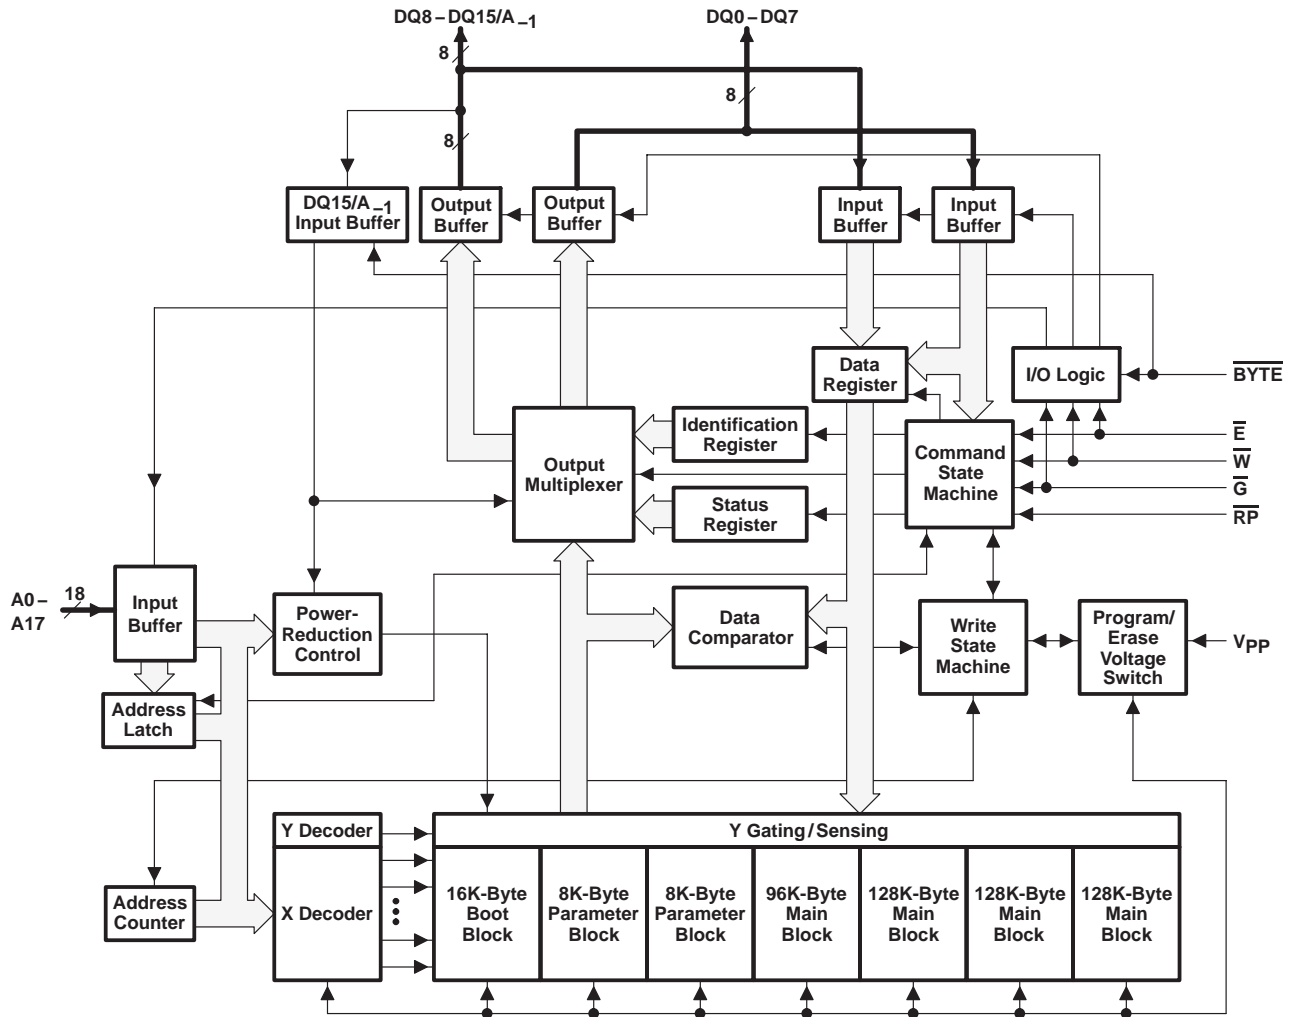

Embedded program and block-erase functions are fully automated by an on-chip write state machine (WSM), simplifying these operations and relieving the system microcontroller of these secondary tasks. WSM status can be monitored by the on-chip status register to determine progress of program/erase tasks. The device features user-selectable block erasure.

The TMS28F400BZx flash memory is offered in a 44-pin PSOP. It is available in two temperature ranges: 0°C to 70°C and – 40°C to 85°C.

device symbol nomenclature

functional block diagram

architecture

The TMS28F400BZx uses a blocked architecture to allow independent erasure of selected memory blocks. The block to be erased is selected by using any valid address within that block.

block memory maps

The TMS28F400BZx is available with the block architecture mapped in either of two configurations: the boot block located at the top or at the bottom of the memory array, as required by different microprocessors. The TMS28F400BZB (bottom boot block) is mapped with the 16K-byte boot block located at the low-order address range (00000h to 01FFFh). The TMS28F400BZT (top boot block) is inverted with respect to the TMS28F400BZB (bottom boot block) since the boot block is located at the high-order address range (3E000h to 3FFFFh). Both of these address ranges are for word-wide mode. Figure 1 and Figure 2 show the memory maps for these configurations.

boot-block data protection

The 16K-byte boot block can be used to store key system data that is seldom changed in normal operation. To protect data within this memory sector, the $\overline{\text{RP}}$ pin can be used to provide a lockout to eliminate either accidental erase or program operations. When $\overline{\text{RP}}$ is operated with normal TTL/CMOS logic levels, the contents of the boot block cannot be erased or reprogrammed. Changes to the contents of the boot block can be made only when $\overline{\text{RP}}$ is at V_{HH} (nominally 12 V) during normal write/erase operations.

parameter block

Two parameter blocks of 8K bytes each can be used as a scratch pad to store frequently updated data. Alternatively, the parameter blocks can be used for additional boot- or main-block data. If a parameter block is used to store additional boot-block data, caution should be exercised because the parameter block does not have the boot-block data-protection safety feature.

main block

Primary memory on the TMS28F400BZx is located in four main blocks. Three of the blocks have storage capacity for 128K bytes and the fourth block has storage capacity for 96K bytes.

command state machine

Commands are issued to the CSM using standard microprocessor write timings. The CSM acts as an interface between the external microprocessor and the internal WSM. The available commands are listed in Table 1 and the description of these commands are shown in Table 2. When a program or erase command is issued to the CSM, the WSM controls the internal sequences and the CSM only responds to status reads. After the WSM completes its task, the WSM status bit (SB7) is set to a logic-high level (1), allowing the CSM to respond to the full command set again.

operation

Device operations are selected by entering standard JEDEC 8-bit command codes with conventional microprocessor timing into an on-chip CSM through I/O pins DQ0–DQ7. When the device is powered up, internal reset circuitry initializes the chip to a read-array mode of operation. Changing the mode of operation requires a command code to be entered into the CSM. Table 1 lists the CSM codes for all modes of operation.

The on-chip status register allows the progress of various operations to be monitored. The status register is interrogated by entering a read-status-register command into the CSM (cycle 1) and reading the register data on I/O pins DQ0–DQ7 (cycle 2). Status-register bits SB0 through SB7 correspond to DQ0 through DQ7.

Table 1. Command State Machine Codes for Device Mode Selection

| COMMAND CODE ON DQ0–DQ7† | DEVICE MODE |
|--------------------------------|----------------------------------|
| 00h | Invalid/Reserved |
| 10h | Alternate Program Setup |
| 20h | Block-Erase Setup |
| 40h | Program Setup |
| 50h | Clear Status Register |
| 70h | Read Status Register |
| 90h | Algorithm Selection |
| B0h | Erase-Suspend |
| D0h | Erase-Resume/Block-Erase Confirm |
| FFh | Read Array |

† DQ0 is the least significant bit. DQ8–DQ15 can be any valid 2-state level.

SMJS400E – JUNE 1994 – REVISED JANUARY 1998

command definition

Once a specific command code has been entered, the WSM executes an internal algorithm generating the necessary timing signals to program, erase, and verify data. See Table 2 for the CSM command definitions and data for each of the bus cycles.

Following the read-algorithm-selection-code command, two read cycles are required to access the manufacturer-equivalent code and the device-equivalent code. The codes are shown in Table 4 and Table 5.

Table 2. Command Definitions

| COMMAND | BUS CYCLES REQUIRED | FIRST BUS CYCLE | | | SECOND BUS CYCLE | | |
|---|---------------------------|-----------------|---------|--------------|------------------|---------|----------------|
| | | OPERATION | ADDRESS | CSM INPUT | OPERATION | ADDRESS | DATA IN/OUT |
| Read Operations | | | | | | | |
| Read Array | 1 | Write | X | FFh | Read | X | Data Out |
| Read Algorithm-Selection Code | 3 | Write | X | 90h | Read | A0 | M/D |
| Read Status Register | 2 | Write | X | 70h | Read | X | SRB |
| Clear Status Register | 1 | Write | X | 50h | | | |
| Program Mode | | | | | | | |
| Program Setup/Program (byte/word) | 2 | Write | PA | 40h or 10h | Write | PA | PD |
| Erase Operations | | | | | | | |

| Erase-Suspend/ Erase-Resume | 2 | Write | X | B0h | Write | X | D0h |

Legend:

- BEA Block-erase address. Any address selected within a block selects that block for erase.
- M/D Manufacturer-equivalent/device-equivalent code
- PA Address to be programmed
- PD Data to be programmed at PA
- SRB Status-register data byte that can be found on DQ0–DQ7
- X Don't care

status register

The status register allows the user to determine whether the state of a program/erase operation is pending or complete. The status register is monitored by writing a read-status command to the CSM and reading the resulting status code on I/O pins DQ0–DQ7. This is valid for operation in either the byte- or word-wide mode. When writing to the CSM in word-wide mode, the high order I/Os (DQ8–DQ15) can be set to any valid 2-state level. When reading the status bits during word-wide read operation, the high order I/Os (DQ8–DQ15) are set to 00h internally so the user only needs to interpret the low order I/Os (DQ0–DQ7).

After a read-status command has been given, the data appearing on DQ0–DQ7 remains as status-register data until a new command is issued to the CSM. To return the device to other modes of operation, a new command must be issued to the CSM.

Register data is updated on the falling edge of \overline{G} or \overline{E} . The latest falling edge of either of these two signals updates the latch within a given read cycle. Latching the data prevents errors from occurring should the register input change during a status-register read. To ensure that the status-register output contains updated status data, \overline{E} or \overline{G} must be toggled for each subsequent status read.

The status register provides the internal state of the WSM to the external microprocessor. During periods when the WSM is active, the status register can be polled to determine the WSM status. Table 3 defines the status-register bits and their functions.

status register (continued)

Table 3. Status-Register Bit Definitions and Functions

| STATUS BIT | FUNCTION | DATA | COMMENTS |
|------------|-------------------------------|---|--|
| SB7 | Write-state-machine status | 1 = Ready 0 = Busy | If SB7 = 0 (busy), the WSM has not completed an erase or programming operation. If SB7 = 1 (ready), other polling operations can be performed. Until this occurs, the other status bits are not valid. If the WSM status bit shows busy (0), the user must periodically toggle \bar{E} or \bar{G} to determine when the WSM has completed an operation (SB7 = 1) since SB7 is not automatically updated at the completion of a WSM task. |
| SB6 | Erase-suspend status (ESS) | 1 = Erase suspended 0 = Erase in progress or completed | When an erase-suspend command is issued, the WSM halts execution and sets the ESS bit high (SB6 = 1) indicating that the erase operation has been suspended. The WSM status bit is also set high (SB7 = 1) indicating that the erase-suspend operation has been successfully completed. The ESS bit remains at a logic-high level until an erase-resume command is input to the CSM (code D0h). |
| SB5 | Erase status (ES) | 1 = Block-erase error 0 = Block-erase good | SB5 = 0 indicates that a successful block erasure has occurred. SB5 = 1 indicates that an erase error has occurred. In this case, the WSM has completed the maximum allowed erase pulses determined by the internal algorithm, but this was insufficient to completely erase the device. |
| SB4 | Program status (PS) | 1 = Byte/word-program error 0 = Byte/word-program good | SB4 = 0 indicates successful programming has occurred at the addressed block location. SB4 = 1 indicates that the WSM was unable to correctly program the addressed block location. |
| SB3 | V _{PP} status (VPPS) | 1 = Program abort: V _{PP} range error 0 = V _{PP} good | SB3 provides information on the status of V _{PP} during programming. If V _{PP} is lower than V _{PP_L} after a program or erase command has been issued, SB3 is set to a 1 indicating that the programming operation is aborted. If V _{PP} is between V _{PP_H} and V _{PP_L} , SB3 is not set. |
| SB2–SB0 | Reserved | | These bits should be masked out when reading the status register. |

byte-wide or word-wide mode selection

The memory array is divided into two parts: an upper-half that outputs data through I/O pins DQ8–DQ15 and a lower-half that outputs data through DQ0–DQ7. Device operation in either byte-wide or word-wide mode is user-selectable and is determined by the logic state of \bar{BYTE} . When \bar{BYTE} is at a logic-high level, the device is in the word-wide mode and data is written to, or read from, I/O pins DQ0–DQ15. When \bar{BYTE} is at a logic-low level, the device is in the byte-wide mode and data is written to, or read from, I/O pins DQ0–DQ7. In the byte-wide mode, I/O pins DQ8–DQ14 are placed in the high-impedance state and DQ15/A₁ becomes the low-order address pin and selects either the upper or lower half of the array. Array data from the upper half (DQ8–DQ15) and the lower half (DQ0–DQ7) are multiplexed in order to appear on DQ0–DQ7. Table 4 and Table 5 summarize operations for word-wide mode and byte-wide mode, respectively.

| | | | | | | | | | | Device-equivalent code 71h (bottom boot block) |
| Output disable | V _{IL} | V _{IH} | V _{IH} | V _{IH} | X | X | X | X | Hi-Z | Hi-Z |
| Standby | V _{IH} | X | V _{IH} | X | X | X | X | X | Hi-Z | Hi-Z |
| Reset/deep power down | X | X | V _{IL} | X | X | X | X | X | Hi-Z | Hi-Z |
| Write (see Note 1) | V _{IL} | V _{IH} | V _{IH} or V _{HH} | V _{IL} | X | X | V _{PPL} or V _{PPH} | X | Hi-Z | Data in |

X = Don't care

NOTE 1: When writing commands to the '28F400BZx, V_{PP} must be V_{PPH} for block-erase or program commands to be executed and \overline{RP} must be held at V_{HH} for the entire boot-block program or erase operation.

command state machine operations

The CSM decodes instructions for clear status-register, read array, read algorithm-selection code, read status-register, program, erase, erase-suspend, and erase-resume operations. The 8-bit command code is input to the device on DQ0–DQ7 (see Table 1 for CSM codes). During a program or erase cycle, the CSM informs the WSM that a program or erase cycle has been requested. During a program cycle, the WSM controls the program sequences and the CSM responds only to status reads.

command state machine operations (continued)

During an erase cycle, the CSM responds to status read and the erase-suspend commands. When the WSM has completed its task, the WSM status bit (SB7) is set to a logic-high level and the CSM responds to the full command set. The CSM stays in the current command state until the microprocessor issues another command.

The WSM successfully initiates an erase or program operation only when V_{PP} is within its correct voltage range (V_{PPH}). For data protection, it is recommended that \overline{RP} be held at a logic-low level during a CPU reset.

clear status register

The internal circuitry can set only the V_{PP} status bit (SB3), the program status bit (SB4) and the erase status bit (SB5) of the status register. The clear status-register command (50h) allows the external microprocessor to clear these status bits and synchronize internal operations. When the status bits are cleared, the device returns to the read array mode.

read operations

There are three read operations available: read array, read algorithm-selection code, and read status register.

- **Read array**

The array is read by entering the command code FFh on DQ0–DQ7. Control pins \overline{E} and \overline{G} must be at a logic-low level (V_{IL}) and \overline{W} and \overline{RP} must be at a logic-low level (V_{IH}) to read data from the array. Data is available on DQ0–DQ15 (word-wide mode) or DQ0–DQ7 (byte-wide mode). Any valid address within any of the blocks selects that block and allows data to be read from the block.

- **Read algorithm-selection code**

Algorithm-selection codes are read by entering command code 90h on DQ0–DQ7. Two bus cycles are required for this operation. The first bus cycle is used to enter the command code and the second bus cycle is used to read the device-equivalent code. Control pins \overline{E} and \overline{G} must be at a logic-low level (V_{IL}) and \overline{W} and \overline{RP} must be at a logic-high level (V_{IH}). Two identifier bytes are accessed by toggling A0. The manufacturer-equivalent code is obtained on DQ0–DQ7 with A0 at a logic-low level (V_{IL}). The device-equivalent code is obtained when A0 is set to a logic-high level (V_{IH}). Alternatively, the manufacturer- and device-equivalent codes can be read by applying V_{ID} (nominally 12 V) to A9 and selecting the desired code by toggling A0 high or low. All other addresses are in the “don’t care” category (see Table 2, Table 4, and Table 5).

- **Read status register**

The status register is read by entering the command code 70h on DQ0–DQ7. Control pins \overline{E} and \overline{G} must be at a logic-low level (V_{IL}) and \overline{W} and \overline{RP} must be at a logic-low level (V_{IH}). Two bus cycles are required for this operation: one to enter the command code and a second to read the status register. In a given read cycle, the status-register contents are updated on the falling edge of \overline{E} or \overline{G} , whichever occurs last within the cycle.

boot-block programming/erasing

Should changes to the boot block be required, \overline{RP} must be set to V_{HH} (12 V) and V_{PP} must be set to the programming voltage level (V_{PPH}). If an attempt is made to write, erase or erase-suspend the boot block without \overline{RP} at V_{HH} , an error signal is generated on SB4 (program-status bit) or SB5 (erase-status bit).

A program-setup command can be aborted by writing FFh (in byte-wide mode) or FFFFh (in word-wide mode) during the second cycle. After writing FFh or FFFFh during the second cycle, the CSM responds only to status reads. When the WSM status bit (SB7) is set to a logic-low level, signifying termination of the nonprogram operation, all commands to the CSM become valid again.

TMS28F400BZT, TMS28F400BZB

524 288 BY 8-BIT/262 144 BY 16-BIT

BOOT-BLOCK FLASH MEMORIES

SMJS400E – JUNE 1994 – REVISED JANUARY 1998

normal programming

There are two CSM commands for programming: program setup and alternate program setup (see Table 1). After the desired command code is entered, the WSM takes over and correctly sequences the device to complete the program operation. During this time, the CSM responds only to status reads until the program operation has been completed, after which all commands to the CSM become valid again. Once a program command has been issued, the WSM cannot normally be interrupted until the program algorithm has been completed (see Figure 3 and Figure 4). Taking \overline{RP} to V_{IL} during programming aborts the program operation. During programming, V_{PP} must remain at V_{PPH} . Only 0s are written and compared during a program operation. If 1s are programmed, the memory cell contents do not change and no error occurs.

A program-setup command can be aborted by writing FFh (in byte-wide mode) or FFFFh (in word-wide mode) during the second cycle. After writing all 1s during the second cycle, the CSM responds only to status reads. When the WSM status bit (SB7) is set to a logic-high level, signifying the nonprogram operation is terminated, all commands to the CSM become valid again.

erase operations

There are two erase operations that can be performed by the TMS28F400BZx devices: block erase and erase suspend/erase resume. An erase operation must be used to initialize all bits in an array block to 1s. After block-erase confirm is issued, the CSM responds only to status reads or erase-suspend commands until the WSM completes its task.

- **Block erasure**

Block erasure inside the memory array sets all bits within the addressed block to logic 1s. Erasure is accomplished only by blocks; data at single address locations within the array cannot be individually erased. The block to be erased is selected by using any valid address within that block. \overline{RP} must be at V_{HH} for changing the data content of the boot block. Block erasure is initiated by a command sequence to the CSM: block-erase setup (20h) followed by block-erase confirm (D0h) (see Figure 5). A two-command erase sequence protects against accidental erasure of memory contents.

Erase setup and confirm commands are latched on the rising edge of \overline{E} or \overline{W} , whichever occurs first. Block addresses are latched during the block-erase-confirm command on the rising edge of \overline{E} or \overline{W} (see Figure 10 and Figure 11). When the block-erase-confirm command is complete, the WSM automatically executes a sequence of events to complete the block erasure. During this sequence, the block is programmed with logic 0s, data is verified, all bits in the block are erased, and finally, verification is performed to ensure that all bits are correctly erased. Monitoring of the erase operation is possible through the status register (see the subsection, "read status register").

- **Erase suspend/erase resume**

During the execution of an erase operation, the erase-suspend command (B0h) can be entered to direct the WSM to suspend the erase operation. Once the WSM has reached the suspend state, it allows the CSM to respond only to the read-array, read-status-register, and erase-resume commands. During the erase-suspend operation, array data should be read from a block other than the one being erased. To resume the erase operation, an erase-resume command (D0h) must be issued to cause the CSM to clear the suspend state previously set (see Figure 5 and Figure 6).

automatic power-saving mode

Substantial power savings are realized during periods when the array is not being read. During this time, the device switches to the automatic power-saving (APS) mode. When the device switches to this mode, I_{CC} is typically reduced from 40 mA to 1 mA ($I_{OUT} = 0$ mA). The low level of power is maintained until another read operation is initiated. In this mode, the I/O pins retain the data from the last memory-address read until a new address is read. This mode is entered automatically if no address or control pins toggle within a 200-ns time-out period. At least one transition on \overline{E} must occur after power up to activate this mode.

reset/deep power-down mode

Very low levels of power consumption can be attained by using a special pin, \overline{RP} , to disable internal device circuitry. When \overline{RP} is at a CMOS logic-low level of $0.0\text{ V} \pm 0.2\text{ V}$, an I_{CC} value on the order of $0.2\text{ }\mu\text{A}$, or $1\text{ }\mu\text{W}$ of power, is achievable. This is important in portable applications where extended battery life is of major concern.

A recovery time is required when exiting from deep power-down mode. For a read-array operation, a minimum of $t_{d(RP)}$ is required before data is valid, and a minimum of $t_{rec(RPHE)}$ and/or $t_{rec(RPHW)}$ in deep power-down mode is required before data input to the CSM can be recognized. With \overline{RP} at ground, the WSM is reset and the status register is cleared, effectively eliminating accidental programming to the array during system reset. After restoration of power, the device does not recognize any operation command until \overline{RP} is returned to a V_{IH} or V_{HH} level.

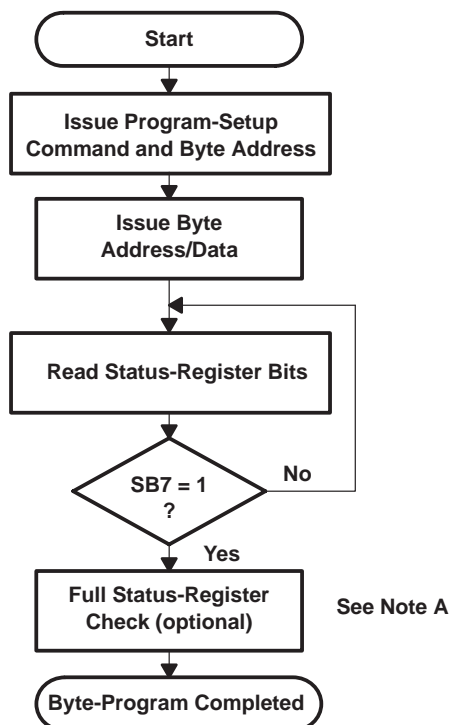

Should \overline{RP} go low during a program or erase operation, the device will power down and, therefore, will become nonfunctional and data being written or erased will be invalid or indeterminate, requiring that the operation be performed again after power restoration.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)[†]

| | |
|---|---------------------------|
| Supply voltage range, V_{CC} (see Note 2) | – 0.6 V to 7 V |
| Supply voltage range, V_{PP} (see Note 2) | – 0.6 V to 14 V |
| Input voltage range: All inputs except A9, \overline{RP} | – 0.6 V to $V_{CC} + 1$ V |
| \overline{RP} , A9 (see Note 3) | – 0.6 V to 13.5 V |
| Output voltage range (see Note 4) | – 0.6 V to $V_{CC} + 1$ V |
| Operating free-air temperature range, T_A , during read/erase/program: L suffix | 0°C to 70°C |
| E suffix | – 40°C to 85°C |
| Storage temperature range, T_{stg} | – 65°C to 150°C |

[†] Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTES: 2. All voltage values are with respect to V_{SS} .

3. The voltage on any input can undershoot to – 2 V for periods less than 20 ns.

4. The voltage on any output can overshoot to 7 V for periods less than 20 ns.

MECHANICAL DATA

DBJ (R-PDSO-G44)

PLASTIC SMALL-OUTLINE PACKAGE

- NOTES: A. All linear dimensions are in millimeters.
 B. This drawing is subject to change without notice.
 C. Body dimensions do not include mold flash or protrusion.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
