Description

The V6309 and V6319 are microprocessor supervisory circuits used to monitor the power supplies in μ P and digital systems. They provide excellent circuit reliability and low cost by eliminating external components and adjustments when used with 5 V powered or 3 V powered circuits.

These circuits perform a single function: they assert a reset signal whenever the V_{DD} supply voltage declines below a preset threshold, keeping it asserted for at least 140 ms after V_{DD} has risen above the reset threshold. The only difference between the two devices is that the V6309 has an active-low RESET output (which is guaranteed to be in the correct state for V_{DD} down to 1 V), while the V6319 has an active-high RESET output. The reset comparator is designed to ignore fast transients on V_{DD} . Reset thresholds suitable for operation with a variety of supply voltages are available.

Low supply current makes the V6309/V6319 ideal for use in portable equipment. The V6309/V6319 come in a 3-pin SOT-23 package

Application Information

Negative-Going V_{DD} Transients

In addition to issuing a reset to the microprocessor during power-up, power-down, and brownout conditions, the V6309/V6319 are relatively immune to short duration negative-going V_{DD} transients (glitches). Fig. 8 shows typical transient duration vs. Reset comparator overdrive, for which the V6309/V6319 do not generate a reset pulse. The graph was generated using a negative-going pulse applied to V_{DD} , starting 0.5 V above the actual reset threshold and ending below it by the magnitude indicated (reset comparator overdrive). The graph indicates the maximum pulse width a negative-going V_{DD} transient can have without causing a reset pulse. As the magnitude of the transient increases (goes farther below the reset threshold), the maximum allowable pulse width decreases. Typically, for the V6309L and V6319M, a V_{DD} transient that goes 100 mV below the reset threshold and lasts 20 μ s or less will not cause a reset pulse. A 0.1 μ F bypass capacitor mounted as close as possible to the V_{DD} pin provides additional transient immunity.

Ensuring a Valid Reset Output down to $V_{DD} = 0$ V

When V_{DD} falls below 1 V, the V6309 $\overline{RESET}$ output no longer sinks current, it becomes an open circuit. Therefore, high-impedance CMOS logic inputs connected to $\overline{RESET}$ can drift to undetermined voltages. This presents no problem in most applications, since most μ P and other circuitry is inoperative with V_{DD} below 1 V. However, in applications where $\overline{RESET}$ must be valid down to 0 V, adding a pull-down resistor to $\overline{RESET}$ causes any stray leakage currents to flow to ground, holding $\overline{RESET}$ low (Fig.10). R1's value is not critical; 100 k Ω is large enough not to load $\overline{RESET}$ and small enough to pull $\overline{RESET}$ to ground. A 100 k Ω pull-up resistor to V_{DD} is also recommended for the V6319, if $\overline{RESET}$ is required to remain valid for $V_{DD} < 1$ V.

Interfacing to μPs with Bidirectional Reset I/O

Interfacing to μPs with Bidirectional Reset Pins

Microprocessors with bidirectional reset pins (such as the Motorola 68HC11 series) can connect to the V6309 reset output. If, for example, the V6309 $\overline{\text{RESET}}$ output is asserted high and the μP wants to pull it low, indeterminate logic levels may result. To correct this, connect a $4.7\text{ k}\Omega$ resistor between the V6309 $\overline{\text{RESET}}$ output and the μP reset I/O (Fig. 11). Buffer the V6309 $\overline{\text{RESET}}$ output to other system components.

Benefits of Highly Accurate Reset Threshold

Most μP supervisor ICs have reset threshold voltages between 5% and 10% below the value of nominal supply voltages. This ensures a reset will not occur within 5% of the nominal supply, but will occur when the supply is 10% below nominal. When using ICs rated at only the nominal supply $\pm 5\%$, this leaves a zone of uncertainty where the supply is between 5% and 10% low, and where the reset may or may not be asserted.

The V6309L/T and V6319L/T use highly accurate circuitry to ensure that reset is asserted close to the 5% limit, and long before the supply has declined to 10% below nominal.
