

VA2708

**DUAL HIGH-SPEED, FAST-SETTLING,
HIGH OUTPUT CURRENT
OPERATIONAL AMPLIFIER, $A_{CL} \geq 3$**

T-79-07-20

FEATURES

- Fast Settling Time: $\pm 0.1\%$ in 150ns
- High Slew Rate: 90V/ μ s
- Large Gain-Bandwidth: 100MHz
- Full Power Bandwidth: 4.8MHz at 6V p-p
- Ease Of Use: Internally Compensated for $A_{CL} \geq 3$ with 50° - 60° Phase Margin
- Large Output Current: ± 50 mA
- Low Supply Voltage Operation: ± 4 V
- Minimal Crosstalk: >90dB Separation
- Short Circuit Protection
- Available In Commercial and Military Versions

DESCRIPTION

The VA2708 offers the high-speed and fast-settling advantages of the VA708 in a dual package configuration. The high slew rate, output drive and open-loop gain allows the amplifier to fit analog amplification and high-speed processing applications capable of driving large capacitance loads at high speeds.

The VA2708 is offered in an 8-pin Cerdip, plastic or metal can package, as well as a 20-pin LCC.

ABSOLUTE MAXIMUM RATINGS

Supply Voltages ± 6 V
Differential Input Voltage ± 9 V
Common Mode Input Voltage $|V_S| - 0.5$ V
Power Dissipation (Note 1) 450mW
Output Short Circuit Current Duration (Note 2) Indefinite
Operating Temperature Range:

Commercial (2708 J, K) 0° to 70°C
Military (2708 S) -55° to +125°C

Storage Temperature Range -65° to +150°C
Lead Temp. Range (Soldering to 60 Sec.) 300°C

Note 1: Power derating above $T_A = 70^\circ\text{C}$ to be based on a maximum junction temperature of 150°C and the following thermal resistance factors:

PACKAGE	θ_{JC} (°C/W)	θ_{JA} (°C/W)
DIP	75	180
TO-99	115	250

Note 2: Continuous short circuit protection is allowed on one amplifier per time up to the following case and ambient temperatures:

PACKAGE	T_C (°C)	T_A (°C)
DIP	100	30
TO-99	75	(Note 3)

Note 3: Long duration shorts (>5 sec) will result in junction temperature exceeding 150°C which may result in part damage.

APPLICATION INFORMATION

AC Characteristics

The 35MHz 10dB crossover point of the VA2708 is achieved without feed forward compensation, a technique which can produce long tails in the recovery characteristics. The single pole rolloff follows the classic 20dB/decade slope to frequency approaching 50MHz. The 10dB (3.2 V/V) phase margin of 50°, even with a capacitive load of 50pF, gives stable and predictable performance down to non-inverting gain configurations of approximately 3 V/V (inverting gains of -2V/V). At frequencies beyond 50MHz, the 20dB/decade slope is disturbed by an output stage zero, the damping factor of which is dependent upon the R_L , C_L load combination. This results in loss of gain margin (gain at loop phase = 360°) at frequencies of 70 to 100MHz which at a gain margin of 5dB ($R_L = 2K$, $C_L = 50pF$) results in a peak in the gain of 3 amplifier configurations as shown in Figures 3 and 4.

Figure 3 shows a blow up of the open loop characteristics in the 10MHz to 200MHz frequency range, as well as the corresponding closed loop characteristics for a gain of 3 non-inverting amplifier at similar load conditions. It should be noted that the open loop characteristic does not show the additional phase shift covered by the input capacitance pole — this is why the closed loop peaking at 30 to 40MHz is greater than what would be expected from the 50 to 60 degrees of phase margin indicated by the open loop characteristics. Corresponding small signal step response characteristics show well behaved pulse waveforms with 16-33% overshoot.

The input capacitive pole can be neutralized by adding a feedback capacitor to R_2 . The value of capacitance is selected according to $R_1 C_{IN} = R_2 C_{FB}$, where C_{IN} is the sum of the common mode and differential input capacitance $\approx 5pF$. For $R_2 = 2R_1$, $C_{FB} = C_{IN}/2 \approx 2.5pF$.

Figure 4 shows the results of this feedback capacitor addition. Neutralizing the input capacitance demonstrates the peaking that can result from the loss of gain margin at 70 to 100MHz. As the load time constant ($R_L C_L$) increases the peaking gets progressively worse $\approx 6dB$ at $R_L = 2K$, $C_L = 50pF$. The step response waveforms are as expected with a very strong 88MHz ring being exhibited at $R_L = 2K$, $C_L = 50pF$ and no overshoot at $R_L = 50\Omega$, $C_L = 5pF$.

Layout Considerations

As with any high-speed wideband amplifier, certain layout considerations are necessary to ensure stable operation. All connections to the amplifier should be kept as short as possible, and the power supplies bypassed with 0.1 μF capacitors to signal ground. It is suggested that a ground plane be considered as the best method for ensuring stability because it minimizes stray inductance and unwanted coupling in the ground signal paths.

To minimize capacitive effects, resistor values should be kept as small as possible, consistent with the application.
